"2. *Anæmia and Exhaustion.* — Puerperal mania has been known to come on in females in regard to whom no other cause was discovered for its appearance than the fact that they have lost a large quantity of blood during some stage of labour; and the anæmia which is sometimes seen to such a marked degree in patients who are the subjects of puerperal mania, has been recognised by some authors as a characteristic cause and feature of the disease, more particularly in its chronic forms. Dr Marshall Hall, indeed, has, as a general principle, attributed the occurrence of mania in puerperal females principally to the exhaustion so common to their condition, combined with some degree of intestinal irritation. But mere, simple anæmia and exhaustion, either by hæmorrhage or even lactation, is not of itself sufficient to produce mania. At all events, the alleged cause is very, very often present in practice without the alleged effect following. The theory at best, if applicable at all, is applicable only to a very limited number of cases, and affords no more satisfactory explanation of the origin of the disease than does the more general statement that puerperal mania results from

"3. *The Peculiar State of the Sexual System which occurs after Delivery.*—This theory was that pronounced by Dr Gooch, in his original essay on Puerperal Insanity. He explained and illustrated his hypothesis by calling to mind the intimate sympathy that exists between all parts of the body and the sexual system in its periodic actions, and by insisting on the high degree of nervous susceptibility induced in lying-in women as a result of the organic changes that succeed delivery. But even when thus explained, the theory hardly helps us to a clearer comprehension of the real origin of the disease. Bearing in mind the peculiar nervous excitability of a puerperal patient, we can understand why she should be more readily acted on by any agent capable of producing a morbid action of the brain or mind at such a time, rather than under other circumstances; but the nature of the morbific agent still remains to be determined. Nervous susceptibility, in a greater or less degree, is confessedly common, to a greater or less extent, to all puerperal women; and yet only a limited number of them are attacked with puerperal mania. Perhaps this fact can only be explained, as it seems to me, by supposing that in those so attacked there is present some specific morbid alteration which acts on the enfeebled and excitable nervous system so as to call forth the peculiar phenomena that characterise the disease. The scalpel and microscope have hitherto so entirely failed in establishing, in the brain itself or its envelopes, any determinate pathological changes in connection with puerperal insanity, in its more acute forms at least, and earlier stages, that we are perhaps so far justified in laying it down as a high probability, that 'the specific morbid alteration' in the economy which constitutes the pathological cause and essence of puerperal insanity does not exist in the solids of the body, or rather, let me say, of the encephalon. Various circumstances, on the other hand, appear to show that the specific morbid alteration in question exists, in the first instance at least, in the presence of a morbid change or morbid agent in the blood; or, in other words, that the disease originates in a state of blood-poisoning, or

"4. *Toxæmia.*—The absolute want of any determinate pathological changes in the brain or its membranes in recent fatal cases of puerperal mania—the rapidity with which the disease sometimes comes on, as well as the rapidity also with which it occasionally disappears, and the phenomena themselves of the malady, so similar as they are in character, at their first supervention, to the toxicological phenomena of blood-poisoning by alcoholic and narcotic poisons,—are all circumstances pointing to the probable toxæmic origin of puerperal insanity. But if you ask further, What is the special morbid change, or what is the special morbid agent in the blood, which, when accumulated there in sufficient quantity, produces puerperal mania? then I can only answer, We know not yet, and will not know till pathological chemistry—which is still in its first infancy—has grown and advanced to an extent and certainty infinitely beyond its present very limited bounds. Some men have already ventured to name the probable poison which produces puerperal mania. Thus I have seen it referred to the use of various narcotic vegetable poisons, of alcohol, and latterly of chloroform. The gentleman who has taken up this last notion,—forgetting that puerperal mania was as well known and as prevalent before the discovery of chloroform as it is now,—reasons exactly as that Medical logician did, who, when denouncing the introduction of vaccination, ascribed to it all the evils which had occurred in the world from the decline and fall of the Roman Empire down to the breaking out of the French Revolution. Let me here merely state that I have seen puerperal insanity occur after the use of chloroform in labour, but certainly not more frequently than I have seen it occur without the use of chloroform during parturition. Some years ago, when this objection to chloroform was first brought out, I went out to the Morningside Lunatic Asylums and there found, with Dr Skae, that eleven case,

of puerperal mania had been admitted from Edinburgh into that institution during the preceding year; but, by an extraordinary series of chances, none of these eleven patients happened to take chloroform during their labours. And I have no doubt that the obstetric use of anæsthetics sometimes prevents, rather than produces, the supervention of puerperal insanity. I have already alluded to an illustrative case. After her first five labours, a patient, as I stated to you, was each time attacked with puerperal insanity, and was each time sent to a lunatic asylum for recovery. During her sixth labour she insisted on getting chloroform, averring that her mind had always previously become upset, in consequence of the extreme intensity of the sufferings which she endured. After this, her sixth labour, and the first in which she used chloroform, no symptoms of insanity appeared. She attributed, and perhaps quite correctly, her escape on this occasion from her dreaded malady, and from the horrors of a lunatic asylum, to the use of chloroform during her labour.

"But, recurring again to the question of the toxæmic origin of puerperal insanity, I would beg further to observe that we have an additional argument in favour of this view, in the fact that in a large proportion of cases of the disease we have present at its commencement a marked state of *Albuminuria.*

Dr John Conolly continues his *Recollections of the Varieties of Insanity,* in the same periodical. Dr Edward Smith communicates some *Remarks on Sun-stroke,* which we will reproduce next week.

The subject of *Glaucoma and Iridectomy* being now in controversy, Mr Hulke has contributed to the 'Medical Times and Gazette' a paper on the subject. He says:

"The treatment of glaucoma by iridectomy, so vehemently attacked by the writer of the article on 'Medical Epidemics—Glaucoma and Iridectomy,' in the 'Dublin Quarterly Journal of Medical Science,' must stand or fall by its results; its success or its failure can be established by experiment only. The experience of the last three years has so completely demonstrated the immense value of Von Graefe's brilliant discovery, that I cannot help regretting the Reviewer's attempts to damage, in the eyes of the Profession, what I have already, in your pages and elsewhere, maintained to be the only known successful treatment of this previously incurable disease. Having, on a former occasion, discussed its relative value in the different forms of glaucoma, and in cognate diseases, I shall not now reopen this part of the subject, but simply state that I have seen no reason to alter the opinions I then expressed. I deny that there has been any suppression of facts, which the Reviewer insinuates; the practice of the Royal London Ophthalmic Hospital is, and has been, before the Profession; and I have reason to believe that the Reviewer, whose style betrays him, was invited, when in London a few months ago, to visit our hospital, that he might see and judge for himself. The desire to thoroughly test the permanency of cures by a considerable period of time, has hitherto prevented me from publishing cases; but, under the present circumstances, I have selected from my case-book a couple, which are good types of acute and subacute glaucoma, and capital examples of what iridectomy can accomplish. The previous loss of one eye by each patient gives these cases an additional interest. I shall abstain from further comments, and let them speak for themselves.

"Case 1.—*Subacute Glaucoma in the Right Eye—Great Contraction of the Visual Field—Dim Perception of large Objects only—Inability to read No.* 20 (*8-line Roman*) *Test-type—Iridectomy—Complete Relief, Patient Reading No.* 1 (*Brilliant*), *and working with her Needle.*

"Esther S., aged 30, was admitted into the Royal London Ophthalmic Hospital, Jan. 17, 1860, with great dimness of the right (her only) eye; this began as an occasional obscuration two years before, but soon became constant. I found she could not read No. 20 test-type, and that there was great contraction of the field of vision, chiefly of its lower part. The pupil was dilated, and nearly motionless. The globe was very hard, much congested, and painful. A haziness of the humours prevented an accurate exploration of the fundus. I could only see that the retinal veins were turgid, and I thought that the optic nerve-entrance was very slightly excavated.

"20th.—I excised the upper and outer one-seventh of the whole iris in its complete breadth.

"24th.—The congestion was much less; the tension of the globe was natural, and she could read the smallest type on her ticket (nearly equal to No. 10 test-type).

"31st.—She was made an out-patient. The redness of the globe had disappeared. Vision continued to improve.

February 10th.—The tension of the globe continues natural. She reads No. 2 test-type.

17th.—Read No 1.

May 11th.—Ditto.

August 25th.—When I last saw her was about a month ago; she read No. 1 with ease, and did needlework. Her left eye-ball was sunken. She said it had been pricked in an operation for squint fourteen years ago; and this statement was borne out by a puckered in-drawn scar in the sclerotic, at the nasal side of the globe, and a great retraction of the caruncle.

"This patient's mother has lost both eyes from glaucoma.

"Case 2.—*Sub-acute Glaucoma in the Left Eye—Complete Blindness—Iridectomy on account of Intolerable Pain—Great Relief—Acute Glaucoma in the Right Eye—No Perception of Objects and a minimun quantitative Perception of Light—Iridectomy—Complete Relief of the Pain, and the Patient able to read average Type and do Needlework.*

"Mary B., aged 64, sought relief at the Royal London Ophthalmic Hospital on account of intolerable pain in her left eye, which had been quite blind for several months. She was a pale, feeble, nervous woman, mother of ten children, supported herself by her needle, and often stitched from nine o'clock in the morning till ten o'clock at night. Early in 1859 she was an inmate of St Thomas's Hospital with erysipelas in the leg, and while there had fever. At this time what seems to have been sub-acute glaucoma commenced in the left eye; it became exceedingly painful; its sight failed, and in four months was quite lost. When she came under my care in 1859, the cornea of this eye was dull and vesicated; the pupil widely dilated and fixed; there was great ciliary congestion, and the subconjunctival veins were particularly swollen and varicose. The eyeball was very hard, and excessively painful. The right eye was occasionally painful and dim, and the flame of a candle appeared to it as if surrounded by a halo. I made an iridectomy in the left eye with the object of relieving the extreme pain, but without any idea of regaining vision, because the ocular tissues were too spoiled to hope for this.

"The operation was successful, and when I saw her on Tuesday, July 26, the congestion had subsided; she had none of the former severe pain, but occasionally a slight ache only, and expressed herself greatly relieved. She was now anxious about her right eye, which was painful and soon tired; ita pupil was sluggish, its anterior chamber small, and the subconjunctival veins varicose. The field of vision at 1′ distance had an area scarcely as large as the palm of my hand, and she could with difficulty pick out the letters of No. 16 test-typo (Jaëger). The globe was a little hard; there was commencing excavation of the optic nerve entrance; and very slight pressure caused pulsation of the vena and arteria centralis retinæ. Foreseeing that acute symptoms were impending, I strongly urged her to come into the hospital on the Friday following, and to let me make an iridectomy in this (her only) eye. When the time came, she got frightened and stayed away. On the Saturday night an outbreak of acute glaucoma took place. She was seized with violent pain in the eyeball, severe headache, rapid and complete blindness, vomiting, and great prostration. On Sunday there was a slight remission, she could just distinguish light and shade. On Tuesday (August 2), when she was brought to the hospital, the great hardness of the globe indicated excessive intra-ocular tension. The cornea was dull, the pupil dilated and motionless; the ciliary region had a dull red colour; the radicles of the efferent ciliary veins encircled the cornea with arches, and their trunks were greatly swollen and highly tortuous. She was suffering agonizing pain, and had not the faintest perception of objects, and quantitative perception of light was reduced to a minimum. I at once put her under the influence of chloroform, and made an iridectomy upwards. In consequence of her moving, owing to anæsthesia being incomplete, the conjunctiva, which was very friable, tore away from the forceps with which I fixed the globe, and the incision into the anterior chamber was smaller than I intended. I enlarged it to the necessary extent with scissors, and then drew out and excised, up to its extreme periphery, a large segment of the iris, in its whole breadth.

"August 5.—Greatly relieved; had a little pain last night, but has none now; she can see my fingers, but cannot count them. From this time she made steady progress. On the 23rd she could count my fingers at three feet distance, and could tell the back from the palm of my hand.

"September 23.—She found her way to the hospital alone.

"November 1.—With a + 16″ lens she easily read No. 10 test-type (pica), and was again at needlework."

Mr H. H. Raymond reports a case of *Rheumatic Fever with Endocarditis,* treated without depletion or mercury. We reproduce the Author's remarks upon the case:

"In this case I could get from the patient no history of previous disease; but the sudden and violent onset of the heart affection made me suspect it; and the suspicion in a great degree directed the treatment. It subsequently turned out that, when a child, she had had an acute attack of rheumatic fever. The treatment, consisting in the total absence of depleting agents, and in the use of sedatives and nourishment, was pursued solely on the merits of the case as it stood. Although the rheumatic affection was most acute, there was that about the patient which gave plain warning against bleeding and mercury, and indicated an opposite course. If the heart mischief could be checked and life supported, she would probably get well. The blisters, both over the heart and the joints, were followed by marked relief; and in each case I adopted the plan of using a number of small ones, instead of a large one, for they are just as efficacious, and less irritating. Opium produced no effect whatever, while the henbane was of great service from the very first dose. I was careful not to check the diarrhœa that came on on the 26th, for, taken in conjunction with the absence of perspiration throughout the case, it looked much more like a benefit than an injury. It was coincident with the improvement of the patient, and stopped in forty-eight hours of its own accord.

"My object in publishing this case is not to point to it as one treated on any system, for I cannot but believe that systematic treatment of diseases is the ruin of Medicine. The stimulants were by no means urgently given, but solely with the view of keeping up the action of a heart that was labouring under the difficulties of disease, which, as I rightly conjectured, were partly recent, and partly of old standing. The only sound inference from this, and similar cases, is, not that the stimulating plan is always the right one for rheumatic fever, but that there are instances in which it is the only method of saving life."

Dr Sweeting communicates some observations on the *Leprosy of the West Indies.*

'The Dublin Medical Press' contains a report of *Two Cases of Ranula* by Dr T. G. Geoghegan. We reproduce the cases.

"*True Ranula, with Dilatation of the Submaxillary Duct.*

"A stout, dark-complexioned young woman, previously healthy, presented herself at the City of Dublin Hospital, having a tumour of about the size of a large Spanish nut in the floor of the mouth. It was lodged beneath the free portion of the tongue, at the left side of the frænum. The swelling was rather prominent and uniformly convex, presented a bluish translucent appearance at its most prominent point, and fluctuated distinctly. Although destitute of pain and tenderness, it was inconvenient in consequence of its creating the sensation of a foreign body in the mouth. Its walls were moderately thin. No

satisfactory cause could be assigned for its development, nor was there any sign of ulceration or abrasion of the adjoining mucous surface.

"The general condition of the swelling led me to determine on attempting the cure by excision of a portion of the sac. Having transfixed the latter, therefore, with a tenaculum, and drawn it well upwards, I removed a tolerably large elliptical piece of the anterior wall of the tumour by a stroke of the scissors. The sac immediately collapsed, and about half an ounce of a glairy, transparent, inodorous fluid escaped. A plug of lint was now introduced into the cavity. There was hardly any bleeding, and the trivial operation was scarcely attended with pain. The excised portion was found to consist of three layers; in the centre, a thin but firm one of condensed fibro-cellular structure; whilst, on the outer surface of this, was the mucous membrane of the floor of the mouth, and, within, what appeared to be the mucous lining of the submaxillary duct, expanded internally on the swelling. A few days subsequently, the probe discovered a track leading from the deepest part of the cavity, backwards and downwards for half an inch. This, from its character and relations, I did not doubt was the submaxillary duct. On the day but one afterwards, the cavity of the swelling was found quite exposed, its inner surface smeared with puriform matter, and the edges of the artificial opening red and healthy. On the subsequent day, the cavity had contracted, and was beginning to granulate. Its interior was now touched with a solution of nitrate of silver. On the seventh day, the track above noted was shorter, and the cure nearly complete. Two months subsequently, there was a slight tumescence at the original seat of the tumour, which yielded a glairy fluid as before on puncture with a grooved needle. Slight occasional twinges of pain were also experienced in that situation. There was also more redness than at the corresponding point of the opposite side. After the lapse of four months no further increase was observable. At the end of eight months the patient again presented herself for the relief of another complaint. The original disease was now found to have been cured, without the employment of any ulterior measures. After a year the part remained quite exempt from recurrence of the swelling. Occasional pain, of which she was still sensible, I referred to the circumstance, that, from other causes, her general health had declined.

"2nd. *Congenital Ranula, with partial Suppuration of the Sac.*

"In 1850, I visited the child of Mr C., in consultation with Dr Bagot. This was a puny infant, eight months old, having premonitory indications of water on the brain. The mother informed us, that the swelling was visible at birth, and had since increased gradually. It had now attained the size of a small apple, and occupied nearly the entire breadth of the floor of the mouth, from its anterior part to about the junction of the middle and posterior thirds of the tongue, to the under surface of which it was rather closely attached for nearly the above extent, commencing a little behind the point of the organ. The tongue rode on its upper surface as a sort of flattened cake. The frænum linguæ was obliterated. The front aspect of the swelling was uniform, convex, of a red colour, fluctuated distinctly, and presented numerous vascular twigs ramifying beneath the mucous membrane. At the lower and anterior part of the tumour, there was an irregular prominence corresponding to the seat of the sublingual glands, and also an abrupt projection externally beneath the chin. There was no pain on pressure, but the tongue was thrust towards the roof of the mouth, thus preventing the child from feeding except when the end of the bottle was passed towards the base of the organ.

"Under the circumstances of this case, it was considered expedient by Dr Bagot and myself to resort, in the first instance, to palliative measures, until the other more serious accompaniments had been, if possible, surmounted. To remove the impediments to respiration and nutrition created by the tumour, seemed the only pressing indication. This was accordingly effected by puncturing it with a grooved needle, about an inch external to the median line, when a considerable quantity of a thin, turbid fluid, of a dirty yellowish brown colour, exuded. The opening was then moderately enlarged. A similar opening was made at a corresponding point of the opposite side of the tumour, the least vascular point of the surface having been selected. The oozing of blood was trivial. The swelling had now collapsed, but was not entirely empty. The enlargement under the chin had, however, disappeared. On the next day there was a slight increase of the tumour beneath the tongue. Further treatment of the ranula was now arrested by more pressing cerebral and pulmonary disturbances, under which the little patient not long afterwards succumbed. No opportunity was allowed of examining the parts.

"In neither of these cases was any calculous or sabulous matter discovered in the interior of the tumour, or in the contents.

"In the first of the above examples of ranula, sufficient evidence seems afforded that the disease really consisted in dilatation of the excretory duct of the submaxillary gland. This appears established by the constitution of the walls of the sac, which, like the above canal, consisted of a mucous membrane supported by an envelope of dense cellular structure; by the narrow track leading backwards in the direction of the gland; and, lastly, by the nature of the contents of the tumour. Dupuytren states that pathological examination has not established that the disease is seated in the Whartonian duct. The appearances, however, in the present case, go some way at least to solve the doubt. That distinguished surgeon also hints (although he has not supported his view by any very definite facts) that tumours in this situation may occasionally consist merely of a serous sac, or possess a more complex nature.

"In the second example above recorded, the seat of the disease, considered as in the salivary duct, although matter of inference merely, is supported by the structure of the sac (as far as was indicated by the edge of the incision), and by the gradual growth, configuration, and painlessness of the swelling on pressure. The semi-purulent character of its contents renders it probable that the lining membrane had been at some time the seat of inflammatory action. This case further distinctly refutes the notion of Dupuytren that such tumours are never congenital, and sustains the views of earlier observers to the opposite effect. The assumed closure of the openings of the submaxillary (and more rarely of the sublingual) ducts has not been verified by clinical observation, and seems merely an assumption; although, of course, inflammatory action, or perhaps superficial or aphthous ulceration of the adjoining mucous membrane, appears to be adequate to the production of such a result. Indeed, the translucent swelling described by me in my observations on glossitis, as noticed in the direction of the duct beneath the tongue, may possibly be the result of temporary occlusion of the apertures just alluded to; whilst such occlusion, when the accompanying inflammation is unrelieved by prompt and suitable treatment, may possibly hasten the occurrence of sublingual abscess. The occasional formation of calculus by the deposition of the carbonate and phosphate of lime of the retained secretion, is obviously to be viewed, not as the cause, but rather as a consequence of the disease, and is but an exceptional occurrence.

"As respects the methods in vogue for combating the disease, the various procedures from time to time recommended sufficiently attest that success has, perhaps, not been very usual. Mere incisions appear on all hands to have been viewed as palliative only, and justly so. Excision of the whole swelling is probably reserved for some ultra-adherent of the school of 'conservative surgery.' Injection seems based on a misapprehension of the nature of the complaint, and accordingly has yielded negative results. The maintenance of an opening for the continuous discharge of the secretion, with a view to the final contraction of the cavity, appears to have found most favour with practitioners. The methods, however, employed for this end, apart from their occasional failure, I venture to consider as unnecessarily operose in their character, and tedious and inconvenient in their action. Of this nature are the tents and metallic setons, under which latter head may be ranked the silver *bouton à deux têtes* of Dupuytren. Indeed, this instrument does not seem to present any practical advantage over the setons of the earlier surgeons. Under its use the cure also has been often tedious. Thus, in one instance, the instrument was worn for several months, whilst the shortest period was fifteen days: in one, there appears to have been a relapse. The figure of Dupuytren's instrument—its presence also as an inconveniently-shaped foreign substance in the mouth, and the fœtor attendant on the accumulation of particles of food in the cavity of its stem, are obvious objections to its use. Excision of a sufficient portion of the outer wall of the sac appears adequate to prevent closure of the opening by cicatrization, and consequent recurrence of the disease, and thus fulfils all the indications requisite for the cure, provided due attention be paid to the after-treatment, which should include, when necessary, moderate stimulation of the remainin portion of the edges and lining membrane of the sac. In the first of the cases now presented, the disease was cured in seven days, and with scarcely any annoyance or pain to the patient. There does not appear any valid reason for adopting the advice of restricting the method of partial excision of the sac-wall to those ranulæ which are of considerable size, or whose parietes are thick and resisting—conditions which, indeed, seem of an unusual kind. The translucent and semi-globular swellings occasionally met with in the mucous membrane of the interior of the cheeks, or (more rarely) on the gums, are probably pathologically analogous to the ranula, and formed by occlusion of the ducts of the buccal glands. To the eye, they rather strikingly resemble the small serous cysts so often found embedded in the exterior of the kidney."

PARISIAN CORRESPONDENCE.

In going round the wards of the Charite with M. Beau, a novice will be not a little puzzled at seeing him scrutinize closely the finger-nails of each newly-admitted patient, telling him occasionally, after a few moments' examination of his cuticular appendage, "My friend, you had a bad illness so many months ago, a very severe illness, that pulled you down a good deal; and then you had a relapse," and so on. This sort of inverted palmistry puzzled me sorely at first, and I confess that even the explanation, when given, left me very sceptical as to the infallibility of this retrospective fortune-telling. Nevertheless, although I do not believe in Hume the spirit-medium, any more than in Hahnemann and his microdosic followers, I do believe in this sign of the past as indicated by the nails. If you look at the fingers of a man who had typhus fever three months ago, let us say, you will find on the nails, towards their centre (at that interval of time), a transverse furrow, deep and well marked, coinciding with the moment when the check in their nutrition occurred—the depth of the depression being in proportion to the severity of the illness, its breadth with the duration; and the several consecutive relapses if such occurred) being each notched on the ungual appendices as on so many tally-sticks. Few men know that they have the past history of their own cases so thoroughly at their fingers' ends.

Professor Mantegazza, of Milan, has lately made some curious researches on the vitality of the zoosperms of the frog; these he has frozen on the one hand, and parboiled on the other, without being able to extinguish their generative powers. As regards the former case, he has found that the zoosperm will stand four separate and consecutive freezings before its vitality is put an end to; but the fifth repetition of this cool treatment proves a little too much for the minute entity, which in this particular is only half as fortunate as the cat with her nine lives. Another and a very droll discovery made by the same Professor (who, by the way, should be called to order by some member of the Society for the Prevention of Cruelty to Animals) is, that the testicle of one frog may be engrafted into the body of another animal of the same species, so that one "froggy" may "go a-wooing" with the testicles of another froggy, and not at all *à ses propres frais:* this seems a "leetle" too much. His last experiment is far more intelligible than the preceding—in part, at least. He says, "If you transplant into the abdomen (under the skin) of a female frog, a few days before the laying of her eggs, a frog's testicle, such is the attraction between this body and the eggs, that ulceration of the abdominal muscles taken place, the male and female elements coming in contact, and so violently that the frog dies." This last result is, I confess, the only portion of the whole paper which I can conveniently credit. (For further particulars, see Reports of the Academy of Sciences.)

They now make here empty gelatine capsules, which for humanity's sake, ought to be generalized in the, practice of those gentlemen addicted to the giving of nasty medicines. They are in make like the old-fashioned needle-cases—a larger tube (shaped as is the test-tube) fiting over a smaller one, this latter being the reservoir, and varying in width and length according to dose. For the administration of creasote, turpentine, *et hoc genus omne* of unpalatable liquids, they are very convenient. They are not of novel invention, but their general use would be.—'Lancet.'

MEDICAL REGISTRAR, IRELAND.—At a meeting of of the Branch Council for Ireland, held, pursuant to advertisment, on Friday, the 24th August, Dr. Apjohn in the chair, William Edward Steele, M.D., Registrar to the King and Queen's College of Physicians, was elected Registrar and Secretary to the Branch Council, in the room of Dr. Maunsell.

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

THE MEDICAL CIRCULAR.

WEDNESDAY, SEPTEMBER 5, 1860.

THE PROROGATION OF PARLIAMENT.

Parliament is up; the Members are gone to shoot partridges, and Ministers to prepare their plans for another campaign. What has the last Parliament done for our Profession? Big with promise, what has it achieved? There was a Bill introduced for the redress of Poor-law Medical grievances, and notwithstanding the energy with which it was pressed by Mr Griffin, and the hopeful spirit of its proposer, Mr Paget, M.P., it was so unsatisfactory to a considerable number of the Profession, and so coldly received by the House, that it was speedily withdrawn from criticism. It was understood that another Bill would be introduced during the Session, to give the Poor-law Surgeons an opportunity to consider it during the recess; but this expectation has not been realised. It is not probable, however, that this important subject will be allowed to drop; the evils are too wide-spread and too generally confessed to suffer the question to repose in the pigeon-holes of an amateur Member of Parliament. Mr Griffin has exhibited uncommon energy in the advocacy of this question, and would, no doubt, like to see such a conclusion of it as would be a reward of his persevering efforts. He will, therefore, continue to agitate. The Union Surgeons, however, must be more united than they have been, before there can be any serious probability of satisfactory legislation upon the question. Every Union in the country should send a delegate to London, to consider the principles of a new measure: these delegates should be prepared to yield on extreme points, with the view of agreeing upon some general terms of arrangement, and they should not attempt to limit too rigorously the powers of Local Boards. It must be borne in mind that nearly all the most influential Members of the House of Commons are Guardians in their several districts, and they do not desire to see too much centralisation in parochial matters. A *minimum* rate of remuneration should be fixed as a *sine quâ non*; and for the rest, let any new measure be reduced to as simple and intelligible a form as is consistent with the correction of the chief grievances. No private Member will be suffered by the Government to pass an elaborate measure comprehending a variety of purposes and interfering with numerous interests, so that it will be mere loss of time to exercise ingenuity in concocting such a scheme.

During the Session there has been a Bill passed to amend the Medical Act. This measure was brought forward at the instance of the Royal College of Physicians, with the concealed purpose of interdicting the admission of Edinburgh Licentiates into the London College, as now prescribed by the provisions of the Act. This attempt was defeated by the Licentiates. It could hardly be expected that either the Government or the House of Commons would reverse previous legislation upon the exceptional grounds which alone could be urged on behalf of the change. There is not, among the public, sufficient sympathy with the exclusiveness of the Colleges to warrant an expectation of such retrograde legislation. The Colleges may rely upon it, that any step taken by the House of Commons in favour of liberality in Medical government will not be retraced. We may remark upon this subject, that the Government should decisively reject any proposal for altering the Medical Act that is not brought forward, or, at least, has not been considered, by the Medical Council. This is the great representative body of the Profession—imperfectly constructed though it be—and nothing should be done by the Colleges to alter the relations of the several Universities and Colleges to the great mass of the Profession except through its instrumentality. If the Government do not support the Council to this extent, it would be better that it should abolish that body at once, as it would become a screen behind which any amount of selfish and pernicious legislation might be clandestinely attempted.

Some important alterations have been made in the law respecting the payment of Coroners, and much, we hope, to the satisfaction of those officers. Coroners' law is still, however, in a chaotic state, and requires to be dealt with in a larger spirit. Various other matters, such as adulterations and local sanitary requirements, have received the attention of the past Parliament.

With reference to sanitary subjects, we may advert to the passing of an Act providing for the construction of a grand Central Meat Market in the Metropolis. In a recent *résumé* of the important public works executed by the Emperor Napoleon, the formation of a Central Market in Paris occupies a place among the four or five grandest operations of that remarkable genius for government: in England, however, such an achievement seems to be of so little importance, that the public press has scarcely noticed it, except in the way of disparagement; and even the pages of the 'Times' have been vigilantly closed against the advocacy of the design. Surely that which is considered by the Press of England and France a work of the greatest honour to an Emperor, should not be deemed either trivial or censurable in the case of private citizens of our own country. It is about six years ago that a few private traders in the neighbourhood of Smithfield wished, in behalf of their own interests, to see various large vacant spaces in Smithfield and its neighbourhood beneficially appropriated, and appealed to Dr Ross to take up the public duty of promoting that object. For the site of Smithfield itself, a great Central Provision Market, in lieu of that huge opprobrium of civilisation Newgate Market, was suggested: the neighbouring sites had been already included in a design for a Railway Terminus, which had been vigorously promoted during twenty years by the indefatigable advocate of public improvements, Mr Charles Pearson. So soon as Dr Ross proposed the design of a Market, opposition started from all quarters; the 'Times' leading the attack. That influential organ of public opinion had refused to insert any statement to explain the objects of the promoters, and continued to alarm the public with exaggerated pictures of the mischief that a great Central Meat Market would, in its sovereign opinion, be sure to cause. In order to counteract this opposition, Dr Ross, assisted by some friends, called a Public Meeting in the City of London; and from that time, it is but due to the good sense and fairness of the 'Times' to say that it ceased its antagonism. St Bartholomew's Hospital, the Charterhouse, and other local institutions, however, continued their hostility, and, at length, the Government appointed a Commission, which was presided over by Mr Cowper, M.P., to take evidence upon the subject. At this time the Corporation of London professed their disinclination to incur the vast expense of erecting any new Market, and certainly not, at any rate, unless possession could be confirmed to them of the entire area of Smithfield up to the walls of the Hospital. In the evidence which Dr Ross gave before the Government Commission, however, he proposed a site for the Market which obviated the objections of St Bartholomew's, but which did not in the same degree meet with the concurrence of the Corporation. Having become a member of the Corporation for the express purpose of carrying out his designs, he was in a condition to make the best of his opportunities to induce the influential members of that body to adopt his views. In the course of time, the only opponents left were the officials of the Charterhouse, and the overwise young gentlemen who indite leaders for our contemporary the 'Lancet.' This sort of opposition was, however, too puerile to be feared. We have now the satisfaction of recording that an Act has been pro-

cured, authorising the establishment of a Provision Market on the site indicated by Dr Ross; that this Market will have a Railway Terminus in the basement, by which means goods from every part of England and Scotland will be brought immediately into the Market, and, with the aid of hydraulic lifts, raised to the level of the Market-floor. Everything that experience or art can suggest will be done to make this the most convenient and perfect market that modern times have seen; and it is estimated that it will cost the Corporation of London about half a million of money. Large and commodious Railway Stations will be made in the immediate neighbourhood; and thus, taken in the aggregate, one of the grandest improvements of a public nature that the Metropolis has ever seen will, within the next two or three years, be consummated. The Corporation of London deserves infinite credit for its liberality and devotedness to the public interests in resolving to carry out these great works.

In a sanitary point of view, these works will be of the greatest importance. About two thousand poor persons—paupers, in short—living in the most abject state in dark and comfortless houses, and forming a nidus for the nursing and propagation of epidemic disease, will be removed. Layers and slaughter-houses where four or five thousand animals are killed weekly will be abolished, and the character of the entire neighbourhood will undergo a great improvement. Anything that facilitates the distribution of food must tend to diminish its cost; and we have no doubt, therefore, that the new Market, which we hope to see superior even to the boasted establishment at Paris, and a noble ornament of London, will exercise a powerful influence in promoting the health and well-being of the three millions of people who now inhabit this Metropolis.

SUMMARY OF THE WEEK.

JOHN HUNTER'S TOMB.

Every man who honours the memory of John Hunter, and who can conveniently visit his resting-place in Westminster Abbey, should do so on an early opportunity, to inspect the beautiful tablet which has been sunk, by order of the Council of the College of Surgeons, in the floor of the Cathedral over the site of his grave. It is really one of the most unique and tasteful things in the Abbey, and, so far as it goes, very creditable to the Council. There may still be an opinion among many, that a statue in the Abbey would have been the most honourable way of commemorating the labours of so great a man; but, short of that, the Council have manifested much elegance of taste in the design which they have selected for a memorial tablet. The slab is of polished red granite, inlaid with a Gothic design in brass, which encloses an inscription in Old English letters, descriptive of the character and labours of the man whose revered dust it enshrines. This inscription has already appeared in the CIRCULAR; it characterises John Hunter very appropriately as the "Founder of Scientific Surgery." This slab has been placed about a week, and is at present guarded from the tread of careless sight-seers. While yet bright and untarnished, it should be seen to be admired; by-and-by all its shining brass and beautiful lettering will have been trodden under foot and despoiled of their attractiveness. It is a pity that this tablet is placed where it must necessarily be defaced.

THE OPERATION ON SIR BENJAMIN BRODIE.

The notoriety given to the surgical proceeding for the cure of the malady under which our great Surgeon is labouring has brought the question of Iridectomy to the surface of discussion. The friends of Mr Bowman are following the lead of that gentleman, and express themselves with considerable warmth against the opponents of the operation. On the other hand, there are Surgeons in this Metropolis, as well as in Dublin, who think the operation sometimes mischievous, and frequently hazardous. Mr Dixon, in his recent work, has condemned it; and we know that there are other eminent Ophthalmic Surgeons who regard it as a sort of chirurgical heresy, although Mr Bowman has given to it his faith or his credulity. Graefe's theory is considered rather fanciful, or, at any rate, a doubtful basis for such an operation. Then, again, a mistake was made in the diagnosis in Sir Benjamin's case; and Messrs Hodgson and White Cooper are exceedingly anxious that it should be known that they diagnosed the disease to be cataract, and not glaucoma; and that, not they, but Mr Bowman performed the operation. We think that Mr Bowman would be wise to curb his propensity for disputation and self-justification; for he certainly will not improve either his position or reputation by it in the present instance.

CARELESS SIGNING OF LUNACY CERTIFICATES.

The daily papers have contained an account of a neglect of duty on the part of Mr Jefferys, one of the Parochial Surgeons of St Pancras, who most imprudently signed a certificate to the effect that a person was a dangerous lunatic, without having previously visited the patient. This is one of those instances of irregularity in the discharge of duty, which not even the warmest friends of the Union Surgeons can overlook. The tenderest interests of humanity are confided to the Union Surgeon in relation to the proper care and protection of the lunatics who are committed to his charge. We should, therefore, regard with extreme jealousy any omission of duty by which the interests of this unfortunate and helpless class might be imperilled. We hope that the perfunctory and routine way of signing certificates of lunacy practised in this instance by Mr Jefferys is quite exceptional, and that it will meet with the general condemnation it deserves.

SMOKE!

Sir Benjamin's star is certainly in the ascendant, for his name nearly fills the hemisphere of Medical Journalism. It is shining with peculiar brilliancy this week through a cloud of tobacco-smoke. What powerful motive has induced Sir Benjamin to address the public on the manifold evils of tobacco, it is not easy to say, unless it be lack of occupation, or that love of meditation on speculative topics into which practical men frequently fall when shut out from a participation in the active duties of life—that introspective tendency, perhaps, which made Milton a poet, or that proneness to exercise the mind upon curious crotchet, which made Newton a writer on chronology. However it may be, Sir Benjamin's observations upon the mischievous consequences of smoking are calculated to produce beneficial results. We are fully persuaded of the injury to the system arising from the abuse of this practice, and have witnessed it so often that we have learned to deplore this monster folly of our times. Sir Benjamin adverts to the impairment of vision, and to other affections of the nervous system, induced by this practice: his experience can be corroborated by any individual of ordinary perception. It is difficult to estimate with exactness the dire consequences of this most injurious practice, owing to its being generally associated with another, that of dram-drinking, which is still more pernicious. Snuffing is another dirty and unwholesome habit which Sir Benjamin might have noticed with advantage. Can anything be conceived more absurd than that of a man feeding his nose with a brown powder by the aid of a spoon? Is there any figure so ludicrous as that of a man who, whilst gravely discoursing in a large company, is reduced to the necessity of keeping guard over his nose with a brown pocket-handkerchief? The powers of digestion are always impaired when this practice is carried to excess. Then look at the heavy-eyed, somnolent, incurious smoker, who, in the very thick of the most exciting conversation, wraps himself in his cloud like another Jupiter, utterly indifferent to all the concerns of this world. That lethargic mind is robbed of half its powers. The solace of the pipe is purchased at so high a price, that we can hardly believe that any rational man who foresaw the ultimate cost would consent to the sacrifice. It is time, indeed, that a protest was raised against this practice, and we thank Sir Benjamin for making it. This is far better than denouncing Special Hospitals.

REPORT ON MEDICAL EDUCATION.

(We annex a very important Report by the General Committee of Education of the Medical Council. We are unable at present to comment on the several recommendations of the Council; but we cannot withhold our praise from the suggestions for establishing a Preliminary Examination in Arts in connection with a code of Medical Examination.)

Report of the General Committee on Education, adopted by the General Council of Medical Education and Registration of the United Kingdom, June 23, 1860.

"The Committee on Education, composed of the whole Council, have held several Meetings during this Session of Council, the Minutes of which are herewith presented.

"The Committee recommend the Council to defer for the present the consideration of the subject of the 'Visitation of Examinations,' regarding which the Minutes contain a full Report from a Sub-Committee.

"The Resolutions agreed to by the Committee, which they recommend the General Council to adopt, are as follows:

"I.—GENERAL EDUCATION AND EXAMINATION.

"The Medical Council are of opinion that it is desirable—

"1. That all Students pass an Examination in General Education before they commence their professional studies.

"2. That, as far as may be practicable, Testimonials of Proficiency granted by the National Educational Bodies, according to the following list, be accepted, with such additions as the Medical Council may from time to time think proper to make:

- A Degree in Arts of any University of the United Kingdom, or of the Colonies, or of such other Universities as may be specially recognised from time to time by the Medical Council.
- Oxford Responsions or Moderations.
- Cambridge Previous Examinations.
- Matriculation Examination of the University of London.
- Oxford Middle Class Examinations, Senior and Junior.
- Cambridge Middle Class Examinations, Senior and Junior.
- Durham Middle Class Examinations, Senior and Junior.
- Durham Examinations for Students in Arts in their second and first years.
- Dublin University Entrance Examination.
- Queen's University, Ireland, two years Arts' Course for the Diploma of Licentiate in Arts.
  - Preliminary Examinations at the end of the A.B. course.
  - Middle Class Examinations.
  - Matriculation Examinations.
- An Examination by any other University of the United Kingdom, equivalent to the Middle Class Examinations of Oxford and Cambridge.

"3. That the Examination on General Education be eventually left entirely to the Examining Boards of the National Educational Bodies recognised by the Medical Council.

"4. That Students who cannot produce any of the Testimonials referred to in the Second Resolution, be required to pass an Examination in Arts, established by any of the Bodies named in Schedule (A) of the Medical Act, and approved by the General Council; provided that such Examination shall be, in every case, conducted by a Special Board of Examiners in Arts.

"5. That, without professing to lay down any complete scheme of General Education for persons intending to become Members of the Medical Profession, the Committee recommend that the scheme of Examination in Arts of the Licensing Bodies be, as nearly as practicable, similar to that of any one of the National Educational Bodies above specified.

"6. That after October 1st, 1861, all Medical Students be required to be registered.

"7. That the lists of Students registered be closed within fifteen days after the commencement of each Session or Term.

"8. That no Student beginning Professional Study after September, 1861, be registered who has not passed an Arts Examination, in conformity with Resolutions 2 or 4.

"9. That the several Bodies in Schedule (A) of the Medical Act, either jointly or severally, open a Register for Students commencing their Studies in Medicine, in the form annexed.

SCHEDULE.

REGISTER OF MEDICAL STUDENTS.

No.	Name.	Date of Birth.	Place of Birth.	Present Residence.	Date of Registration.	Place of Registration.	Registering Body.	When and by what Body the Examination in Arts was conducted, and its Date.
1	A B	—	—	London	—	University College, London	University of London	Matriculation Examination of University of London; May, 1861
2	C D	—	—	Birmingham	—	Birmingham General Hospital	Royal College of Surgeons of England	Oxford Middle Class Examination; Aug 1861

"10. That the said Register be opened on the first day of each Session or Term, and remain open for fifteen days; and that within seven days after its close, the Officer in charge be required to transmit a duly-authenticated copy thereof to the Registrar of the Branch Council of that Division of the United Kingdom to which the Body or Bodies belong.

"11. That the Registrar of the Branch Council lay the list before the Branch Council, in order that the Branch Council may take whatever steps may seem necessary to secure its accuracy; and that it thereafter be transmitted, with any remarks by the Branch Council thereon, to the Executive Committee.

"12. That the Executive Committee shall arrange these Returns, and publish annually an Alphabetical List of the names contained in them.

"13. That the Licensing Bodies shall have power to admit exceptions as to the time of Registration, if satisfactory to them, and shall transmit lists of such exceptions to the Branch Council of the part of the United Kingdom in which such exceptions have been granted, with the grounds stated.

"14. That the various Educational and Licensing Bodies be requested to transmit to the Registrar of the General Council, Returns, embodying any alterations which they may from time to time introduce into their courses of General Study and Examinations, which qualify for the Registration of Medical Students.

"II.—PROFESSIONAL EDUCATION.

"15. That the age of twenty-one be the earliest age at which any Professional Licence shall be obtained.

"16. That four years of Professional Study be required after the Examination in General Education."

"III.—PROFESSIONAL EXAMINATIONS.

"17. That the Professional Examinations be divided into at least two distinct parts; that the first be not undergone until after the termination of two years of Study, and the final Examination not until after the termination of four years of Study.

"18. That the first Professional Examination be conducted partly in writing and partly *viva voce*; and that such parts as admit of it be made as practical and demonstrative as possible.

"19. That the second Examination be conducted partly in writing, partly *viva voce*, and practically as far as may be convenient and attainable.

"20. That the Professional Examinations be held by the several Licensing Bodies (except in Special cases) at stated periods, to be publicly notified.

"21. That Returns from the Licensing Bodies under Schedule (A) be made annually, on the 1st of January, to the General Medical Council, stating the number and names of the Candidates who have passed their respective final Examinations, and the number of those who have been rejected."

"The General Medical Council having, in the course of last year, expressed their opinion on the manner in which the General Education of Medical Students ought to be obtained, and stated the principles which appeared to them proper for the regulation of Professional Examinations, consider it undesirable, during the present Session, to enter upon any details of the requirements for the so-called higher Degrees and qualifications.

"But, at the same time, they would record their opinion, that it is not desirable that any University of the United Kingdom should confer a Degree in Medicine, whether that of Bachelor or Doctor, upon Candidates who have not graduated in Arts, or passed all the Examinations required for the Bachelorship in Arts, or the Examinations equivalent to those required for a Degree in Arts."

GENERAL CORRESPONDENCE.

PAINS AND PENALTIES ACT FOR THE ESTABLISHMENT OF A CRIMINAL LUNATIC ASYLUM IN ENGLAND.

To the Editor of the Medical Circular.

SIR,—In your excellent and independent publication of the 29th ultimo, an abstract is given of the Act recently passed for "the custody and care of Criminal Lunatics" in England, amongst the provisions of which—and, I must say, to my great astonishment—are pains and penalties to be inflicted on the Superintendent and other officials of an Asylum, in sums varying from 20*l.* to 2*l.*, in the event of such parties "striking," or "wounding," or "ill-treating" any of the inmates thereof. Should any such delinquencies take place, due punishment of course should follow; but I consider it a most gratuitous insult to the Specialty connected with the treatment of the insane of any class, that it should have been thought necessary in this, the nineteenth century, to have special penal provisions thus introduced into the above Act, when the ordinary law and tribunals for its administration have the fullest powers for punishing any such most unlikely occurrences. It is derogatory in the highest degree to the professional head of such an establishment, to suppose it possible that any one in so responsible a position could be guilty of "striking, wounding, ill-treating, or wilfully neglecting" those entrusted to his charge; and if his subordinates even thus forget themselves, the means are at hand to make them feel the consequences of such misconduct. Has it been found necessary, in the establishing of other hospitals, to have penalties and imprisonment provided for their Medical men and attendants? No such thing. In the corresponding Act of the legislature for the erection, &c. of an Asylum in Ireland for the custody of Criminal Lunatics, it was never dreamed of by its promoters thus to disgrace the humanity of the Profession in Ireland; nor has it ever been found necessary, since the passing of that Act in 1843, to prosecute any official for "striking, wounding," and so forth. Seeing, then, that this disgrace has been perpetrated—(by-the-bye, what was the "Association of Medical Officers of Asylums and Hospitals for the Insane" about, that it did not protest in time against these penal provisions?)—it becomes absolutely requisite that a very close eye should be kept on any new Bill that may be introduced in the ensuing Session of Parliament, having disgraceful penal clauses embraced in it in connection with the management of Asylums generally; and with this view chiefly it is that I now venture to call attention to so important a subject through your influential columns.

I am, Sir, your obedient servant,

Sept. 1, 1860. VIGIL.

[The subject of the foregoing letter deserves the watchful consideration of the Medical Officers of Asylums. Surely they will not quietly submit to the insult.—ED. MEDICAL CIRCULAR.]

LETTER BY SIR BENJAMIN BRODIE ON THE USE AND ABUSE OF TOBACCO.

SIR,—Having been applied to some time since to join in a petition to the House of Commons that they would appoint a Committee to inquire into the effects produced by the prevailing habit of tobacco-smoking, I declined to do so; first, because it did not appear to me that such a Com-

mittee would be very competent to discuss a question of this kind; and, secondly, because, even if they were so, I did not see that it would be possible for Parliament to follow up, by any act of legislation, the conclusions to which they might have arrived. Nevertheless I am ready to admit that the subject is one of no trifling importance, and well worthy of the serious consideration of any one who takes an interest in the present and future well-being of society. From these considerations it is that I now venture to address to you the following observations.

The empyreumatic oil of tobacco is produced by distillation of that herb at a temperature above that of boiling water. One or two drops of this oil (according to the size of the animal) placed on the tongue will kill a cat in the course of a few minutes. A certain quantity of the oil must be always circulating in the blood of an habitual smoker, and we cannot suppose that the effects of it on the system can be merely negative. Still, I am not prepared to subscribe to the opinion of those who hold that, under all circumstances, and to however moderate an extent it be practised, the smoking of tobacco is prejudicial. The first effect of it is to soothe and tranquillize the nervous system. It allays the pains of hunger, and relieves the uneasy feelings produced by mental and bodily exhaustion. To the soldier who has passed the night in the trenches before a beleaguered town, with only a distant prospect of breakfast when the morning has arrived; to the sailor, contending with the elements in a storm; to the labourer, after a hard day's work; to the traveller in an uncultivated region, with an insufficient supply of food,—the use of a cigar or a tobacco-pipe may be not only a grateful indulgence, but really beneficial. But the occasional use of it under such circumstances is a very different matter from the habit of constant smoking which prevails in certain classes of society at the present day.

The effects of this habit are, indeed, various, the difference depending on difference of constitution, and difference in the mode of life otherwise. But, from the best observations which I have been able to make on the subject, I am led to believe that there are very few who do not suffer harm from it to a greater or less extent. The earliest symptoms are manifested in the derangement of the nervous system. A large proportion of habitual smokers are rendered lazy and listless, indisposed to bodily and incapable of much mental exertion. Others suffer from depression of the spirits, amounting to hypochondriasis, which smoking relieves for a time, though it aggravates the evil afterwards. Occasionally there is a general nervous excitability, which, though very much less in degree, partakes of the nature of the *delirium tremens* of drunkards. I have known many individuals to suffer from severe nervous pains, sometimes in one, sometimes in another part of the body. Almost the worst case of neuralgia that ever came under my observation was that of a gentleman who consulted the late Dr Bright and myself. The pains were universal, and never absent; but during the night they were especially intense, so as almost wholly to prevent sleep. Neither the patient himself nor his medical attendant had any doubts that the disease was to be attributed to his former habit of smoking, on the discontinuance of which he slowly and gradually recovered. An eminent surgeon, who has a great experience in ophthalmic diseases, believes that in some instances he has been able to trace blindness from amaurosis to excess in tobacco-smoking, the connection of the two being pretty well established in one case by the fact that, on the practice being left off, the sight of the patient was gradually restored. It would be easy for me to refer to other symptoms, indicating deficient power of the nervous system, to which smokers are liable; but it is unnecessary for me to do so; and, indeed, there are some which I would rather leave them to imagine for themselves than undertake the description of them myself in writing.

But the ill effects of tobacco are not confined to the nervous system. In many instances there is a loss of the healthy appetite for food, the imperfect state of the digestion being soon rendered manifest by the loss of flesh and the sallow countenance. It is difficult to say what other diseases may not follow the imperfect assimilation of food continued during a long period of time. So many causes are in operation in the human body which may tend in a greater or less degree to the production of organic changes in it, that it is only in some instances we can venture to pronounce as to the precise manner in which a disease that proves mortal has originated. From cases, however, which have fallen under my own observation, and from a consideration of all the circumstances, I cannot entertain a doubt that, if we could obtain accurate statistics on the subject, we should find that the value of life in inveterate smokers is considerably below the average. Nor is this opinion in any degree contradicted by the fact that there are individuals who, in spite of the inhalation of tobacco-smoke, live to be old, and without any material derangement of the health; analogous exceptions to the general rule being met with in the case of those who have indulged too freely in the use of spirituous and fermented liquors.

In the early part of the present century tobacco-smoking was almost wholly confined to what are commonly called the lower grades of society. It was only every now and then that any one who wished to be considered as a gentleman was addicted to it. But since the war on the Spanish Peninsula, and the consequent substitution of the cigar for the tobacco-pipe, the case has been entirely altered. The greatest smokers at the present time are to be found, not among those who live by their bodily labour, but among those who are more advantageously situated, who have better opportunities of education, and of whom we have a right to expect that they should constitute the most intelligent and thoughtful members of the community. Nor is the practice confined to grown-up men. Boys, even at the best schools, get the habit of smoking, because they think it manly and fashionable to do so; not unfrequently because they have the example set them by their tutors, and partly because there is no friendly voice to warn them as to the special ill-consequences to which it may give rise where the process of growth is not yet completed, and the organs are not yet fully developed.

The foregoing observations relate to the habit of smoking as it exists among us at the present time. But a still graver question remains to be considered. What will be the result if this habit be continued by future generations? It is but too true that the sins of the fathers are visited upon their children and their children's children. We may here take warning from the fate of the Red Indians of America. An intelligent American physician gives the following explanation of the gradual extinction of this remarkable people:—One generation of them became addicted to the use of the firewater. They have a degenerate and comparatively imbecile progeny, who indulge in the same vicious habit with their parents. *Their* progeny is still more degenerate, and after a very few generations the race ceases altogether. We may also take warning from the history of another nation, who some few centuries ago, while following the banners of Solyman the Magnificent, were the terror of Christendom, but who since then, having become more addicted to tobacco-smoking than any of the European nations, are now the lazy and lethargic Turks, held in contempt by all civilized communities.

In thus placing together the consequences of intemperance in the use of alcohol and that in the use of tobacco, I should be sorry to be misunderstood as regarding these two kinds of intemperance to be in an equal degree pernicious and degrading.

The inveterate tobacco-smoker may be stupid and lazy, and the habit to which he is addicted may gradually tend to shorten his life and deteriorate his offspring; but the dram-drinker is quarrelsome, mischievous, and often criminal. It is under the influence of gin that the burglar and the murderer become fitted for the task which they have undertaken. The best thing that can be said for dram-drinking is, that it induces disease, which carries the poor wretch prematurely to the grave, and rids the world of the nuisance. But, unfortunately, in this, as in many other cases, what is wanting in quality is made up in quantity. There are checks on one of these evil habits which there are not on the other. The dram-drinker, or, to use a more general term, the drunkard, is held to be a noxious animal. He is an outcast from all decent society, while there is no such exclusion for the most assiduous smoker.

The comparison of the effects of tobacco with those of alcohol leans to the consideration of a much wider question than that with which I set out. In all ages of which we have any record, mankind have been in the habit of resorting to the use of certain vegetable productions, not as contributing to nourishment, but on account of their having some peculiar influence as stimulants or sedatives (or in some other way) on the nervous system. Tobacco, alcohol, the Indian hemp, the kava of the South Sea Islanders, the Paraguay tea, coffee, and even tea, belong to this category. A disposition so universal may almost be regarded as an instinct, and there is sufficient reason to believe that, within certain limits, the indulgence of the instinct is useful. But we must not abuse our instincts. This is one of the most important rules which man, as a responsible being, both for his own sake and for that of others, is bound to observe. Even such moderate agents as tea and coffee, taken in excess, are prejudicial. How much more so are tobacco and alcohol, tending, as they do, not only to the degradation of the individual, but to that of future generations of our species!

If tobacco-smokers would limit themselves to the occasional indulgence of their appetite, they would do little harm either to themselves or others; but there is always danger that a sensual habit once begun may be carried to excess, and that danger is never so great as in the case of those who are not compelled by the necessities of their situation to be actively employed. For such persons the prudent course is to abstain from smoking altogether.

Trusting that you and your readers will excuse me for having occupied so large a space in your columns,

I am, Sir, your obedient servant,

Aug. 27. B. C. Brodie.

HOSPITAL REPORTS.

GUY'S HOSPITAL.

Exostosis under Scapula.—Mr Cock. Necrosis of Tibia—Unreduced Dislocation of Elbow-Joint—Mr Hilton.

(August 14th).—Exostosis under Scapula.

This patient, a boy about twelve years of age, had suffered enlargement of bone under scapula for two years, as stated; but Mr Cock considers it had been a longer period in forming. The gradual increase of growth of bone at length impaired the movements of the arm, and its dimensions had lately rapidly increased, which required removal of bone by excision. After anæsthesia was induced, Mr. Cock made a transverse incision of nearly three inches in length, commencing at the internal margin of scapula across the dorsum, through the integuments down upon the exostosed scapula. The bone deposit was found to be of an excessively hard character, and its attachment very strong. The bony matter was removed with forceps and nippers with some difficulty. Some irregularities were found upon the surface of the bone, which required to be removed by gouging them away. The wound was left open. The operation took a considerable time in performance.

Necrosis of Tibia.—Mr Hilton.

The patient, a young man about twenty-five years of age, was placed under the influence of chloroform. The disease (not the result of injury) commenced some time since, and was seated upon the internal aspect of the bone of the right leg at its lower third. The soft parts and tissues were greatly thickened and enlarged, and three sinuses had formed communicating with each other. Mr Hilton made an incision by opening the sinuses, cutting from the upper to the lower sinus, and then, by another incision, made a crucial flap. Thus, by dissecting to the bone he was enabled to remove the shell of necrosed bone from the cylinder of the "tibia." The part removed had jagged edges, and Mr Hilton thought it included the whole shell of diseased bone. If the disease had been the consequence of injury, its edges would have been smooth on the outline, and not jagged.

Unreduced Dislocation of Elbow-Joint.

This case, a boy about twelve years of age, was admitted into hospital this morning. The dislocation of elbow had occurred about five months since. Upon examination, the joint was found to be in a state of complete rigidity. The head of

radius was forced upon the external condyloid process of humerus. The olecranon was also forced upwards above the fossa. The arm was quite straight, and there was not much swelling of surrounding parts. Mr Hilton considered that the humerus had been fractured at its distal extremity, near the elbow-joint. He concluded that, in the process of union, it had thrown out a large quantity of ossific matter, which had produced anchylosis of joint. The boy was placed under the influence of chloroform. Flexion was attempted, and extension and counter-extension of the elbow was then practised for a considerable time, without success. The elbow still continued rigid, and no reduction or movement of extremities of bones could be effected. After rest, upon again persisting with more force, at first limited flexion was obtained. At length the flexion was accomplished so as to bring the forearm in a right angle with the arm, and considerable deformity relieved. This case exemplified the great revolution which chloroform has introduced into operative surgery. The force brought to bear upon this anchylosed joint would never have been practised without chloroform. It would have been a cruel and almost barbarous practice to submit a patient to what, without the anæsthesia produced by chloroform, would have amounted to torture. Moreover, the resistance of the patient would have rendered the attempt almost impossible.

August 21.

Necrosis of Humerus.—Mr Birkett. Amputation of Leg.—Mr Cock.

Necrosis of Humerus.

The patient, a boy about twelve years of age, had necrosis of the humerus of right arm, from disease. No accident or injury was known to have occurred to cause the disease. He was placed under chloroform. A longitudinal incision was made a little below the head of humerus, for about three inches, exposing bone. A portion of sound bone was required to be moved to reach the necrosed bone; this was necessarily a troublesome and rather tedious process. The chisel and mallet were necessary to be used with considerable patience before the shell could be detached. It was at length brought away whole, about one inch and a quarter in length. More diseased and necrosed bone lay out of reach, on the internal aspect of the shaft of the humerus.

Amputation of Leg.

This was a rather curious and interesting case. The patient was a young woman, twenty-two years of age, of good habit, full condition, and large muscular development. She had had paralysis of left leg from infancy, supposed to have resulted from convulsions or infantile fever. This loss of nervous power and motile function seemed to be limited to the excito-motory system of nerves, and more especially of the lower portion of the limb diseased. The sensibility remained unimpaired, there was no *anæsthesia* of the leg; nevertheless the limb became imperfectly developed, suffered from innutrition, and was of defective growth. The shaft of the femur was much shorter and smaller in circumference than the other. The other thigh was particularly muscular and well developed, so also was the leg, the total difference in length between the diseased and sound limb being fully nine inches. The foot was considerably deformed and inverted. This occurred, no doubt, from want of muscular power to obviate gravitation of the leg and foot inwards, not from malformation, although foot was much smaller than sound one. Mr Cock made a few observations upon this interesting case. He said he should make the double-flap operation. The object was to give a good pad for an artificial leg. He remarked, this was rather longer about, but was compensated to the patient. This patient enjoyed good motion of hip and knee; the loss of power was limited to lower part of the leg and foot. The supply of nervous circulation and energy to the leg and foot were so deficient, that she suffered from sores and extensive ulceration upon the anterior aspect of the lower part of the limb. Under chloroform, the flap operation was done in the usual way. The bones were found so small, that the knife could scarcely be introduced between them.

KING'S COLLEGE HOSPITAL.

Resection of Knee-joint—Lithotrity—Hare-lip.—Mr Fergusson.

Resection of Knee-joint.

Long-existing disease had gone through its usual stages in this diseased knee-joint. The patient, a girl eight years of age, came into hospital about eighteen months since. Strumous disease had exhausted itself in spontaneous cure; and nature, which had accomplished so much, had left a deformed and useless limb. In this case the articular cartilages, ligaments, and synovial membrane had been diseased. The articular cartilages especially were destroyed, and the head of the tibia had formed a union between the condyles of the femur. On her first admission to hospital, nothing more could be done in the way of treatment than extension of the limb; this was practised, and the child went home with leg much more straight than on admission. Neglect occurred, and disease slightly returned, for which she was placed under treatment out of hospital.

Operation. — A lunated incision was carried transversely, making a section of the front aspect of the knee-joint over the lower segment of patella from condyle to condyle. A flap was then dissected upwards to the margin of the superior arch of patella. The cartilages and ligaments being divided, the saw was then applied to this joint, cutting through extremity of femur at a right angle with its shaft, obtaining a slight divergence or inclination in section downwards through the bone. The saw was then applied at the lower margin of patella, and cut through the bone at a right angle as at first, with a slight divergence upwards. Thus, the two incised planes made by the saw met at the posterior or popliteal aspect of the joint, forming the apex or narrow extremity of a wedge. Patella was included in this wedge-shaped piece of excised bone, condyles, and extremity of femur, tibia, and fibula. This operation may be properly designated the *wedge operation*, from the compact, wedge-shaped substance of bone sawed out of the knee-joint. Mr Fergusson remarked that this was either a case for excision or amputation: he said, we never think of amputation now — excision is preferable. This case was especially fitted for excision. It was a case already cured—soft parts sound, and youth to guarantee success. The limb might have been permitted to remain, but the deformity was such that it would be useless and always in the way. Much has been said about loss of blood in these cases. In this operation we had not more loss than half a teaspoonful. There was not a twentieth part of the loss which occurred in the child we have just operated upon for harelip. In this case we made a single incision; formerly the H incision was made, and even more incisions. No doubt there is always some little danger attending all operations, this amongst the rest. We shall obtain for the patient a straight, or, what is better, a very slightly flexed limb—or, perhaps, with a false joint, and the deformity and impediment will be comparatively little. Upon examination of the wedge of bone, fibrous junction had taken place between extremities of the bones of the joint and patella.

Lithotrity.

Mr Fergusson, in continuing the application of the lithotrite to the patient upon whom he operated last week, did not to-day succeed in finding the stone. During the week a small stone had come away, having phosphatic crust, about the size of a small bean.

Hare-lip.

A child eight months old, having double hare-lip, had also exostosis of maxillary bone, at margin of vomer, in removing which considerable hæmorrhage from a deep-seated vessel occurred. To check this, Mr Fergusson resorted to nitric acid, applied at the end of a piece of stick pushed down upon the vessel. He quickly resorted to bringing the widely-distended edges of the lip together, which showed a chasm of singular deformity, and the bleeding by this constriction and pressure speedily ceased. Mr Fergusson remarked, that in such cases he had known surgeons walk about for forty minutes, waiting for hæmorrhage to cease, whereas by finishing the operation it would forthwith cease.

ST GEORGE'S HOSPITAL.

Malignant Ulcer.—Mr Tatum.

These conditions of malignant growths are extremely numerous. Although for many years pathologists have given much attention to the characteristics of these diseases, they remain ill defined, and not completely investigated. Some consider them in all cases constitutional; but we have reason to believe that this does not apply to all, and the exceptions admit of many accidental diseases which assume a malignant character. Amongst the number we may class the form of malignant ulcer which we are about to mention. The subjects of this malignant degeneration, mostly males, are usually in other respects persons of good health and robust constitution, and often display a considerable personal vigour, are tall, and have a good appearance, as was manifested in the case operated upon. It generally occurs late in life, mostly after fifty years of age, and will be manifested at a very advanced period of life. Malignant ulcer, so called, commences in a very imperceptible manner. It is at first strictly limited to the integument by a small ecchymosed-looking spot, which becomes slightly elevated. The skin upon friction becomes abraded, and a dry, crusty secretion exudes. Like lupus, it never heals; and its attacks are limited to the face, neck, and maxillary regions. It increases — sometimes slowly, sometimes rapidly—by spurts, extends in all directions, and ultimately, after expending itself upon soft tissues, assails bones, especially the superior maxillary bone, and external angle of the orbit. When it has arrived at a determinate size, it assumes the appearance of a fleshy, warty excrescence; it frequently commences at the angle, and extends its attack to the eye itself. When that is the case, the conjunctiva becomes ecchymosed, thickens, and enlarges; and it ultimately attacks the sclerotica and cornea, thus entirely destroying the eye, leaving a cavern which becomes filled with a red, vascular fungus. It next attacks the orbit, which it destroys. This disease, different from so-called rodent ulcer, extends and is limited to the bones of the face and jaw, completely destroying all in its career. It eats away the bones in all directions, exposing the floor of the cerebrum, and base of brain. Singularly, the membranes of the brain have evaded its attacks, when they have been otherwise most inveterate, and the sensorium is seldom much disturbed. The patient at length sinks from exhaustion. After removal, it does not return. Mr Tatum stated that he had resorted on several occasions to the use of chloride of zinc for its destruction at the commencement of the disease. The patient, a tall, well-grown, and healthy man of fifty years of age, had malignant ulcer at external angle of right eye. The tumour, about the size of a large plum, was extirpated in the usual way, by circular incision. It consisted of epithelial cells connected by fibrous bands, was colourless, very dense and compact.

MEDICAL SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, June 26, 1860.

F. C. Skey, Esq., President, in the Chair.

A paper, by Dr J. W. Ogle, was read, relating a case of anæsthesia of almost the entire surface of the body, as well as of partial loss of power,

recurring several times, and traceable to the effects of effused products within the spinal canal upon the various spinal nerves. The case was that of a stonemason, aged thirty-two years, of intemperate habits, who rather suddenly lost the use of all his limbs to a certain degree, as well as sensation of the skin almost entirely. The affection began with feelings of "pins and needles" in the legs. There was no affection of the mental functions. Under treatment for eight or nine months, and the use of frequent blisters to the back, he became perfectly well; but since then, for five or six years, he has had a slight return of his illness every winter, which however did not prevent his working. He was admitted into St George's Hospital with very diminished sensation of the skin of both legs as high as the thighs, as also of both arms up to the elbows, and of both cheeks and nose. There was no want of sensation in the skin of the forehead. The patient could walk, but in a very tottering manner; and the arms were much wanting in power. No pain complained of. Under the use of blistering the

spine, and diuretics, chiefly the tincture of cantharides, he became in every way much improved, and was dismissed from the hospital greatly relieved. He subsequently returned, stating that he had lost power in the limbs, and had been affected by numbness of the skin of the upper extremities. He complained of occasional pain in the head. He was again treated with the tincture of cantharides, and also with strychnine and bark. He was a second time dismissed without any numbness, and was able to work. Six months later he was again brought into St George's Hospital in a very heavy and stupefied condition, and with twitching of most of the muscles of the body. In this condition it was difficult to make out to what degree the sensation of the skin was affected, but it did not appear to be very much interfered with. The special senses were in a natural state; but the patient rambled when made to talk. He was cupped and purged. He became delirious, secreting objects under the bedclothes. The pupils of both eyes were very contracted; and the trembling of the muscles became excessive. After a short time he became very irritable, and very angry if the skin of the limbs was at all pinched, as if their sensation was exalted. He was seized with or by a convulsive attack and dyspnœa, and died rather suddenly.

Post-mortem Examination.—It was found that the spinal membranes had been the seat of extensive effusion of "lymph," or albuminofibrinous material. This had in many places accumulated around the roots of the spinal nerves, and was evidently chiefly of old standing. In some places the roots of the nerves were thickly and firmly bound by this material, and this it was no doubt which had given rise to the interference with the motion and sensation of the limbs and face. Moreover, a good deal of soft, yellowish, fibrinous material was met with at the base of the brain, occupying the subarachnoidean tissues, and surrounding the vessels and nerves there met with. Dr Ogle has had a coloured drawing made, showing the presence of the effused material in contact with the spinal nerves, and also showing the microscopical appearance both of the spinal nerves and of the adventitious surrounding material.

A paper, by Mr HENRY LEE, was read on

CASES OF TREPHINING IN SYPHILITIC DISEASE OF THE BONES OF THE SKULL, WITH OBSERVATIONS.

The Author gives the particulars of three cases, in all of which the bones of the skull were very extensively diseased. In the first the outer and middle table of the frontal bone, principally on the left side, and part of the left parietal bone, had become necrosed, but the internal table retained its vitality when the trephine was applied. The inner surface of the portion of the bone which was removed presented a very uneven surface, from whence numerous small, irregular spicula of bone projected. The dura mater, which had been in contact with these, was altered in structure, and did not bleed, as the dura mater usually does when a portion of bone is removed by the trephine. There was here general debility, loss of sensation on the right side of the face, and deafness in both ears. There had been also extensive and long-continued ulceration on the left side of the neck. The removal of the portion of bone, shown in an accompanying drawing, was followed by general restoration of the health, recovery of the sensation of the face (with the exception of a small portion of the right side of the upper lip, which still remains numb), and perfect hearing. This patient has no other treatment excepting a pint of the decoction of sarsaparilla daily. In the second case there was extensive disease of the outer and middle tables of the skull. The patient became, in consequence, subject to a peculiar kind of fit. This commenced with flushing of the face, followed by twitching of the muscles of that part. The fit would then sometimes terminate; at others, however, it would be followed by rigidity of the muscles of mastication and of the other muscles of the body. Some of these fits lasted as much as six hours, during which the patient retained his consciousness. This patient was affected with an ulceration which lasted over a period of between eight and nine years, and which had extended over the skin of the whole right arm, from the shoulder to the wrist. The application of the trephine in this case was made over the right temporal bone: the portion of the internal table removed was slightly roughened, but not nearly so much as in the preceding case. The fits recurred a few hours after the application of the trephine, but ultimately ceased. The ulceration of the right arm, which had existed between eight and nine years, healed, and the patient was restored to a comparative state of health. In the third case the bones of the skull had been extensively destroyed, but in one part the inner table had perished where the outer and middle table still maintained their vitality, as shown in an accompanying drawing. Opposite this point effusion of plastic matter had taken place, and the disease had spread by continuity of action to the brain, and produced red softening of that organ. There was no disease, either in the brain or its membranes, in those situations where the entire thickness of the skull had been removed. In this instance, again, there had been long-continued and most troublesome ulcerations principally of the right leg, and destruction by ulceration of the eye and nostril on one side. The trephine was here applied to the right parietal bone, in the immediate neighbourhood of the portion of the internal table which had perished. The exact spot was not hit upon; but as softening of the brain had already taken place, and the patient was comatose, any operation in this particular instance was too late. The Author dwelt particularly upon the absence of disease in those parts where the entire thickness of the skull had been removed, and concluded from thence that the early removal of the diseased internal table afforded the best chance of success in such cases. It was evident in the last case that the continued contact of the diseased bone had produced the effusion, first, between the bone and dura mater, then between the membranes of the brain, and that the brain itself had ultimately become diseased by continuity of action. Had this diseased bone been earlier removed, the results would not have occurred. The object of trephining in these cases was, then—1st. To remove the cause of irritation from the surface of the dura mater. 2ndly. To allow the discharge of any matter there secreted. 3rdly. To establish a healthy suppuration from one part of the membrane, whereby the irritation caused by the prolonged contact of diseased bone would be relieved. The Author directed particular attention to the prolonged, persistent, and recurring ulceration of the skin, which formed one of the most troublesome symptoms in all the cases. In illustration of the cause of these ulcerations he referred to M. Brown-Séquard's experiments, in which it was shown that by cutting off the sympathetic nervous influence from a part the vessels of that part became dilated; and also to M. Majendie's experiments upon the fifth nerve, by which it was shown that ulceration might follow the abstraction of nervous influence. In the third case destruction of the eye had actually followed, as in Majendie's experiments, and as had also been observed by the Author in a case of fracture of the base of the skull in which the fifth nerve had been completely paralysed. M. Brown-Séquard had also shown that, by irritating certain portions of the nervous system, an animal might be rendered liable to epileptic fits. In Case 2 the Author attributed the occurrence of the fits to the irritation produced in the membranes of the brain by the continued contact of the diseased bone, and concluded that the removal of even a comparatively small portion of that bone, so diseased, was calculated to relieve the irritation, as it certainly appeared to have done in the cases recorded.

A paper, by Dr G. CURSHAM, was read, giving

CASES OF OBSTRUCTION OF THE VEINS OF THE LOWER EXTREMITIES CAUSING ŒDEMA OF THE CORRESPONDING LIMB, OCCURRING IN PHTHISICAL PATIENTS.

The Author relates four cases of the above description, all of which occurred in patients in an advanced stage of phthisis. In three the œdema was confined to one limb, the corresponding veins being found closed with coagula. In one case both limbs were affected, and in this the lower part of the vena cava (as well as both femoral veins) was obstructed. He refers to similar facts published by different authors, and observes that the cases he has recorded correspond closely with those described under the name of phlegmasia dolens. The Author, however, is disposed to think they had some other origin than the one to which that disease has been attributed, and states his reasons for considering them as coming under the class of cases in which coagulation in the veins is produced by the presence of pus or some foreign matter in the blood, and that the subsequent inflammation was owing to the stagnation of the vitiated blood in the vessels.

OUR NOTE BOOK.

AIR IN THE UTERINE VEINS.

M. Depaul related before the Surgical Society of Paris the following instance of sudden death, from penetration of air into the uterine veins, and subsequently into the heart:—On 15th April, 1855, M. Depaul attended, in her first confinement, a woman, aged nineteen, whose pelvis and lower extremities were much deformed, the sacro-pubic diameter of the brim of the pelvis scarcely reaching 3 inches (7½ centimètres) in length. The dilatation of the os uteri was complete forty-eight hours after the beginning of labour; the liquor amnii escaped, but the head did not descend into the pelvis. The head presented obliquely, the vertex being directed towards the right acetabulum. The pains were intense, intermittent, but frequent, and since twenty-four hours a loop of the cord in which no throbbing was perceptible had descended; the heart of the fœtus was, moreover, inaudible. M. Depaul, after a further delay of an hour and a half, perforated the cranium, and with the forceps extracted a full-sized child weighing about eight pounds. The patient recovered rapidly.

Some two years after, she again became pregnant, and M. Depaul resolved on inducing artificial labour at eight months, in the hope that the child might live. At the period agreed on, a powerful uterine injection (*douche vaginale*) was performed, and labour having supervened, it again became necessary to have recourse to perforation of the head. Even after this operation, the extraction of the fœtus presented much difficulty, and metro-peritonitis followed, which imperilled the life of the mother.

A third pregnancy took place, but fortunately the patient miscarried at two months and a half.

She again became gravid towards November 10th, 1859; and on this occasion M. Depaul resolved not to delay beyond seven months and a half the induction of premature labour. On the 20th of June, 1860, in the presence of Dr Tarnier, Fellow of the School of Medicine, in the Section of Midwifery, he therefore administered a first injection, which occasioned a few uterine contractions. A second injection was performed on the same day, and a third on the following evening, with the apparatus in common use at the "Hôpital d'Accouchement," consisting in a forcing-pump fixed to a bucket, from which the water is raised through one tube and discharged through another, with considerable power, into the vagina.

Having placed his forefinger in contact with the cervix, the operator inserted the caoutchouc canula at a distance of about 5 lines from the os uteri. The injection had continued for about five minutes, when a peculiar sound was heard, indicating the escape of air; the instrument was carefully examined, and being found in perfect order, the operation was resumed. After a short interval, the same sound was again noticed, and the patient complained of much pain. A third time air escaped with the water from the pipe, and the operation was interrupted. The patient having then been recommended to rise and take a few steps across the room, fell back in a faint; the pulsation of the radial artery suddenly became imperceptible, and the heart ceased to beat. During twelve minutes no effort was spared to restore suspended animation, but after three incomplete gasps the woman definitely expired.

The Cæsarian operation was then instituted. The texture of the uterus, instead of being dark and turgid, was found pale and colourless, and at each incision air-bubbles and froth escaped with the blood. The child, which at first gave no sign of life, was restored after a hot wine-and-water bath and direct insufflation, but lived fifteen hours only.

On removal of the after-birth, it was found that part of its surface was detached and separated by a certain quantity of air from the uterine wall.

No post-mortem examination of the body was permitted.

Although this method of inducing prematu

labour is frequently resorted to by the principal accoucheurs of Paris, a melancholy occurrence similar to that related above has never before been observed. The instrument has since been the object of careful examination, but the most minute research has failed to detect the imperfection to which the fatal escape of air was due.

M. Depaul assumes that the air forced into the womb was retained within its cavity during the contractions, at the close of each of which it was aspirated by the uterine veins, whence it passed into the cava and into the heart, a direction in which it was further propelled by the *vis à tergo* exerted by the uninterrupted discharge of water into the vagina.

DIPHTHERITIC PARALYSIS.

M. Maingault, who a few years years since wrote a thesis upon this subject, as the result of further experience, comes to the following conclusions: 1. Numerous cases prove that there is a variety of paralysis which deserves the title of diphtheritic paralysis, coming on during the convalescence of diphtheritis and croup; it is evidently the consequence of the primary affection. 2. This paralysis may be local, as paralysis of the velum palati and of the pharynx. 3. Frequently it is also seated at distant parts, sometimes being limited to the lower limbs, and at others extending successively to the various muscles of the body, thus exhibiting a generalised and progressive form. 4. A simple mild case of diphtheria may give rise to a severe and extended attack of this paralysis. 5. Albuminuria is not the determining cause of this paralysis, as in some cases the urine has contained no albumen whatever. 6. It seems to be the result of a disturbance of the nervous system, without any appreciable lesions of the nervous centres. 7. It may terminate fatally, but usually recovery takes place in a space of time occupying from two to eight months.—'Archives Gén.', tome xiv., p. 716, and 'Medical Times.'

DETECTION OF PHOSPHORUS IN CASES OF POISONING.

Scherer has found that the smallest trace of phosphorus may be detected by its reaction with a salt of silver. Phosphorus volatilises even under liquids, at the ordinary temperature, and a piece of paper moistened with nitrate of silver is blackened when suspended over it in a closed vessel.

In order to guard against error, it is necessary, when the fluid contains organic matter, to mix it with pure sulphuric acid, and suspend over it a piece of paper moistened with an alkaline solution of nitro-prussiate of sodium, which would detect the presence of sulphuretted hydrogen by the violet colour produced. If by long contact with air the phosphorus has passed into the state of phosphorous acid, it may still be detected by distilling the liquid with zinc and sulphuric acid, and passing the evolved gas into a solution of nitrate of silver. The phosphoretted hydrogen present produces a black precipitate, which may also be oxidised with nitric acid, and then examined for phosphoric acid in the usual way.—'London Medical Review.'

UREA IN THE LYMPH OF CHYLE.

A. Wurtz has examined the chyle obtained by a fistulous opening in the thoracic duct of a bull which was fed with animal food, and finds in it a considerable quantity of urea. He also finds this substance in the chyle and lymph of other animals, according to the following table, the amount of urea contained in the blood being also stated for the purpose of comparison.

—'London Medical Review.'

INFLUENCE OF FATTY BODIES ON THE SOLUBILITY OF ARSENIOUS ACID.

Blondlot has found that the fatty bodies diminish the solubility of arsenious acid, both in pure water, and slightly alkaline or acid solutions. The slightest contact of arsenious acid with a fatty substance is sufficient to reduce its solubility to 1-15th or 1-20th of that which, *ceteris paribus*, would occur in the absence of the fatty body.

This behaviour explains how it is that sometimes, in medico-legal investigations, arsenic has been looked for in vain in the fluid parts of food really containing arsenic when fat is also present—in soup or milk, for example.—'London Medical Review.'

THE STATE OF THE LUNGS IN DROWNED PERSONS.

The presence or absence of water, or frothy mucus in the lungs, of persons who have died by drowning, has given rise, from Haller downwards, to much controversy. M. Beau, physician of the Hospital of La Charité, has recently instituted on the subject an interesting experimental inquiry, which we find in the 'Archives Générales de Médicine' for July, 1860.

From these researches, it would appear that animals kept completely immersed under water make one inspiration only, and sometimes none whatever. This gasp is followed by the expiration of a certain quantity of air, of which a corresponding amount of water takes the place. The glottis then closes convulsively, and no more water is admitted. The instinctive cessation of all respiratory movements, and the spasmodic constriction of the glottis, would, therefore, account for the smallness of the quantity of fluid which penetrates into the lungs.

The imperative admonition of the necessity of ceasing all efforts of respiration is, according to M. Beau, the result of the natural orifices of the air-passages being kept under water. Thus when, in another series of experiments, dogs, after tracheotomy, were immersed up to the neck only, the artificial orifice of the trachea being kept below the level of the liquid, inspiration was repeated in successive gasps until the bronchi became entirely filled.

From these experiments, M. Beau concludes:

1. The small quantity of frothy mucus found in the lungs of the drowned cannot be regarded as the cause of death, which is due to the interception of air.

2. Penetration of water into the air-passages is prevented by the spasmodic closing of the glottis and the instinctive cessation of all efforts at respiration.

3. The mechanism of asphyxia by drowning differs materially from that which is observed in accumulation of morbid secretions within the chest, as in pulmonary catarrh, for instance; it presents, on the contrary, much analogy with the manner in which death is brought on in tetanus. —'Journal of Practical Medicine and Surgery.'

ARMY MEDICAL DEPARTMENT.

QUESTIONS LATELY GIVEN TO ASSISTANT-SURGEONS IN THE ARMY BEFORE BEING RECOMMENDED FOR PROMOTION.

MEDICINE.

Dr Parkes.

1. Much discussion has taken place with regard to the etiology of yellow fever, and its exact relation to diseases of undoubted malarious origin. Describe the symptoms and treatment of yellow fever, and enter as fully as you can into the questions above alluded to.

2. What are the pulmonary diseases you have had to treat since your entrance into the service? Give their symptoms and treatment, and state any opinions you have formed from your own experience with respect to their causes and the preventive measures which should be adopted.

3. What opinions are now generally received respecting the causes of scurvy? How does the scorbutic taint modify the symptoms of the following diseases: typhus, pneumonia, pleurisy, and dysentery?

4. What are the symptoms and causes of beriberi?

5. What are the chief measures used for purifying water from suspended and dissolved organic substances? What diseases have been supposed to be produced or aggravated by the use of such impure water?

6. What is the ordinary diet of the soldier on home service? Your opinion being asked as to the kind and quantity of food which should be supplied in a campaign in Europe expected to be extremely harassing and laborious, draw up such a scale of diet as will, in your opinion, meet the case.

SURGERY.

Mr Paget.

1. Write such regulations for the general treatment of men nearly drowned as may be carried out by non-professional persons.

2. Describe briefly the characters and the appropriate treatment of burns of different degrees of severity.

3. Enumerate the contagious diseases of the skin (excluding the exanthematic); describe the distinctive characters and treatment of each. How would you try to prevent their spreading in a regiment?

4. Write lists of all that should be prepared for the performance of, and first dressings after, the operations of (1) amputation above the knee; (2) tracheotomy; (3) trephining.

5. What precautions do you observe in the administration of chloroform? In case of any untoward symptoms arising during its administration, what should be done?

6. What are the most frequent conditions of the bones, and the parts around them, in old cases of ununited fracture?

7. What are the principal injuries and diseases of the head for which the removal of bone, by trephining or otherwise, should be generally advised?

ANATOMY, PHYSIOLOGY, &c.

Mr Busk.

1. Describe the diaphragm, its connections, relations, and functions.

2. Describe the fasciæ of the abdomen, together with those of the pelvis and perinæum, in the male.

3. Give an account of the structure and properties, physical and vital, of a middle-sized artery, and of the capillary vessels.

4. What are the conditions upon which the rhythmical movements of the heart depend, and to what causes are its sounds due?

5. What are the chief active principles in opium? Describe in general terms the method of extracting them.

6. What art the wild British poisonous plants which give rise to the most frequent cases of accidental poisoning? What symptoms do they produce?

7. What is yeast? Give the *rationale* of its use in baking bread.

8. Enumerate the principal plants from which sugar is procured. Explain its use as an article of diet; and distinguish grape from cane sugar.

Births, Marriages, and Deaths.

BIRTHS.

Dunn.—August 23, at Feckenham, Worcestershire, the wife of G. P. Dunn, Esq., M.R.C.S., late of Ledbury, of a daughter.

Griffith.—August 28, at Peckham, the wife of John T. Griffith, M.D., F.R.C.S., of a son.

Marshall.—August 26, at Belvedere road, Upper Norwood, the wife of J. Marshall, M.D., of a son.

MARRIAGES.

Duncan.—Holchkis.—August 21, at Ladyfield House, James Matthews Duncan, A.M., M.D., F.R.C.P.E., of Edinburgh, to Jane Hart, youngest daughter of James Holchkis, Esq., of Ladyfield House, Dumfriesshire.

Moule.—Foster.—August 22, at St Mary's Church, Hitchin, the Rev. Frederick J. Moule, to Mary Alicia, third daughter of Oswald Foster, Esq., M.R.C.S., of Hitchin, Herts.

DEATHS.

Acton.—August 25, at Grandisburgh, Woodbridge, Suffolk, Edward Acton, L.S.A. Lond., aged 54.

Armstrong.—August 15, at Collooney, County Sligo, Wm. Armstrong, M.D. Edin., L.R.C.S. Ireland.

Carter.—May 27, at the General Hospital, Cal-

cutta (17 days after his arrival), Robert Carter, Assistant-Surgeon on the Bombay Establishment.

Cook.—August 19, suddenly, at Lamlash, Isle of Arran, Dr Cook.

Elmore.—August 26, at 27 Harley street, Cavendish square, John Richard Elmore, M.D., M.R.C.S. Eng., aged 73. He had been a Member of the Royal College of Surgeons for fifty-four years.

Gallaer.—July 23, at Aspinwall, New Grenada, Dr John Gallaer, Surgeon-in-Chief of the Panama Railroad.

Gibson.—August 13, of disease of the heart, at Armagh, Samuel Gibson, M.B. Univ. Trin. Coll., Dub., Assistant-Surgeon, 12th Lancers.

Harris.—At Nelson, New Zealand, Mr Samuel Harris, who left England as Surgeon on board the vessel 'Golconda.'

Hutchinson.—August 24, at Guildford street, Russell square, aged 76, Ann, widow of Scrope Hutchinson, M.D., late of Dover and Hythe.

Row.—August 24, of disease of the heart, at Lower Homerton, William Row, M.R.C.S. Eng., L.S.A. Lond., aged 53.

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed the examination in the science and practice of Medicine, and received certificates to practise, on Thursday, August 23:—John Alderson, Birmingham; J. V. L. Westmacott, Chorlton Union Workhouse, Manchester.—The following gentlemen also on the same day passed their first examination:—Arthur Richard Beckett, Whitchurch, Salop; James Fowler, Winterton, Lincolnshire; Arthur Trehern Norton, St Mary's Hospital; Edward Parson, King's College; Arthur Roper, Guy's Hospital; Edward Thomas Tibbits, University College.

Medical Promotions in the Legion of Honour.—Messrs. Jules Cloquet and Ricord have just been promoted to the rank of Commanders of the Legion of Honour.

Cambridgeshire Lunatic Asylum.—At a meeting of the visitors of the Cambridgeshire Lunatic Asylum, holden at Fulbourn on Tuesday last, Mr G. W. Lawrence, of the Camberwell House Asylum, London, was appointed Medical Superintendent of the former institution, in the room of Dr Bryan, resigned. The candidates selected for election, out of 110 applications, were: Mr G. Casson, of the Norfolk County Asylum; Mr C. Hills, of the Kent County Asylum; Mr T. Allen, of the Lincoln County Asylum; Mr J. Ellis, of the County Asylum, Hanwell, Middlesex; Mr T. Dixon, of the Wye House County Asylum, Buxton; and Mr G. W. Lawrence. The salary is 300*l.* per annum, with furnished house and coals, and an allowance of 140*l.* per annum in lieu of rations.

The Cholera in Spain.—The 'Siglo Medico' of Madrid contains an article which shows that the cholera has regularly broken out every year in some part of Spain since 1854. From the 1st of May to the 29th of June of this year, 5,344 cases occurred at Malaga, the deaths being 2,267. Many provinces have been invaded, but Madrid has as yet escaped.

Naval Hygiene.—The heat at Malta was excessive during last month, and a very prudent sanitary precaution had been adopted on board the ships of war in port, under the considerate command of Rear-Admiral Codrington, C.B., the senior naval officer in port, with the best results. The usual routine of exercising guns, sails, and such like, was judiciously deferred to the cool of the evening, when the heat of the day was deprived of its extreme intensity. It would be very desirable that a like system be adopted by the Lieutenant-General commanding the Military in garrison.

Impervious Aorta near the Arch in a New-born Child, who lived five Days.—M. Devilliers mentions this case in 'L'Union Médicale' of the 23rd ultimo. The left ventricle was very small, and a probe passed from its cavity upwards towards the arch met with an obliterated canal. The sigmoid valves were in fact glued together, and rendered the vessel impervious. Of course the circulation of fœtal life could accommodate itself to this abnormal state; but extra-uterine life sank under it, although the ductus arteriosus remained widely patent.

Perfect Happiness in Medicine.—M. Duméril, Professor at the Faculty of Medicine and the Museum of Natural History of Paris, has just died at the advanced age of eighty-seven years. The deceased was member of the Academy of Sciences since 1816, and enjoyed great reputation as an indefatigable investigator of natural history. He published numerous works, highly valued for their great lucidity and descriptive exactness. M. Duméril retained up to his decease the clearest intellect, often spoke at the meetings of the Academy, and was listened to with the deference to which his age, experience, and knowledge entitled him. Hardly three weeks ago he took an active part in the discussion touching the longevity of toads, to which we have referred in this journal. The late professor breathed his last in perfect calm, not regretting life, and saying a few hours before dissolution, "I have always been happy."—'Lancet.'

Graduated Types for Trials of Vision.—M. de Jaeger, jun., has just published at Vienna the third edition of the above pamphlet, which has recently been translated into French. It consists of twenty proofs of different types, commencing with the largest (No. 20), and descending by a gradually diminishing scale to the smallest (No. 1), in English, German, and French. The book is extensively used by oculists in Germany, as the amount and kind of vision can at once be described by it. When, for instance, a person is said to read No. 8 at so many inches' distance, and to be able to read for a determined time without fatigue, a very accurate idea is given of the patient's powers of vision.

Cold versus Heat.—The annual deaths by cold and by burns in this country follow a curious law of progression when their frequency is compared with the temperature of the year. Thus the temperature of 1855 was low, and in that year deaths by cold amounted to 195, and deaths by burns and scalds to 3177; and in the year 1857, the temperature being high, the deaths by cold did not exceed 45, and by burns 2717. In the four years out of nine when the annual deaths by cold exceeded 100, the deaths by burns and scalds were 2826 on an average; in the four years when the annual deaths by cold were less than 100, the deaths by burns and scalds were 2710 on an average. The additional fires in cold weather, and the disposition to approach them without due caution, sufficiently explain this, while they also indicate the importance of applying widely the principle of rendering dress non-inflammable.

The New Census Acts.—The new Acts for taking the Census in England and Ireland next April have been issued. The Act for Scotland has not yet received the Royal assent. In the Act for England there are 19, and in the one for Ireland 11 sections. In England the Secretary of State is to superintend the taking of the Census. Every registrar's subdistrict is to be formed into enumerators' divisions. Enumerators are to be appointed, and householders' schedules are to be left at all dwelling-houses, to be filled up as to all persons abiding therein on the night of Sunday, the 7th of April, as to the name, sex, age, rank, profession or occupation, condition and relation to head of family, and "birthplace of every living person," and also whether there were any blind or deaf-and-dumb. There is nothing as to "religious profession" in the English Act, but there is in the one relating to Ireland. The schedules in England are to be collected from the houses on Monday, 8th of April, if possible, and to be corrected if found to be erroneous. The masters of jails, workhouses, hospitals, &c., are appointed enumerators for the occasion, and all overseers and other parochial officers are bound to act as enumerators. Returns are to be obtained of the houseless poor during the night of the 7th of April, and of all persons travelling or on shipboard. A table of allowances to the enumerators in England is to be prepared, and the payments are to be certified to the Registrar-General. The enumerators and other persons employed in the execution of the Act are authorized to ask the questions directed, and every person refusing to answer or wilfully giving a false answer is to forfeit a sum not exceeding 5*l.*, nor less than 1*l.*; one half of the penalty is to be paid to the informer. In Ireland, the police of the Dublin and constabulary forces with other competent persons, as the Lord-Lieutenant may appoint, are on the 8th of April and one or more consecutive days to visit every house, and take an account of the age, sex, religious persuasion, and occupation of all persons; and also, both in England and Ireland, particulars as to the houses, &c. Penalties are to be imposed for not answering and for giving false statements, which fines are to be enforced in a summary manner. The Census is to be laid before Parliament within twelve months after next June.

Cure for Hydrophobia.—The 'Presse Médicale Belge' states, on the authority of Father Legrand de la Liray, late interpreter to Admiral Rigald de Genouilly, and one of the oldest and most venerable missionaries in Tonquin and Cochin China, that in those countries hydrophobia is cured with complete success by boiling a handful of the leaves of Datura Stramonium, or Thorny Apple, in a litre of water, until reduced to one-half, and then administering the potion to the patient all at a time. A violent paroxysm of rage ensues, which lasts but a short time, and the patient is cured in the course of 24 hours. For the benefit of our readers, we may state that the leaves of Stramonium are highly narcotic, and as such are recommended in asthma under the form of cigars, to be smoked as usual; but that the same leaves, taken in large quantities, whether in powder or under the form of a decoction, will produce temporary idiocy. As to its efficacy in confirmed hydrophobia, it seems to be very earnestly recommended by Father Legrand, who declares he has tried it several times, and invariably with success. The great difficulty will of course consist in administering the remedy to the patient, which probably must be done by main force, with the aid of a horn; but on this subject the 'Presse Médicale' is silent.

Sir Henry Holland has sailed for Canada, to join the suite of the Prince of Wales.

M. Jobert's Method of treating Stricture.—The 'France Médicale' of the 11th ult. contains a clinical account of M. Jobert de Lamballe's practice, at the Hôtel-Dieu of Paris, in the treatment of stricture. The French surgeon's opinions are rather sweeping, as he condemns pretty well every mode of treatment save his own, which is described as follows:—Take an emplastic bougie, and soften the extremity at the flame of a lamp; then incorporate more or less alum with it, according to the effect you wish to produce, and gently carry down the instrument to the seat of the stricture. There leave it a quarter of an hour. After two or three applications (the intervals are not mentioned), inflammation of the mucous membrane and discharge follow; the canal becomes disgorged by this transitory catarrh, and a bougie with an olive-shaped extremity passes easily. The case quoted in support is in nowise conclusive, and we must submit that the alum incorporation does not seem to us to present any advantages—rather the contrary. This practice of M. Jobert somewhat resembles the new mode of treating gleet in Paris, alluded to by our own correspondent ('Lancet,' July 28th, p. 99); but practitioners will probably require good proof that these methods are really efficacious, and that they produce no mischief, before they have recourse to them.

Medical Institutions in Torquay.—This town possesses three medical institutions—an Infirmary, a Consumption Hospital, and an Institution for Ladies of reduced means suffering from Affections of the Chest. The Hospital for Consumption admits fifty in-patients at once—twenty-five of each sex. It is open for eight months in every year—from October 1st to June 1st. It restricts its advantages to such cases as are in an early stage, or afford reasonable prospect of undergoing arrest. Suitable cases can return for as many seasons as may be requisite to complete their restoration. In these and in some other respects, the Torquay Hospital for Consumption is unique. For the Erith House Institution for reduced Ladies, a new and appropriate building is now in course of erection. When completed, it will accommodate twenty occupants, who will each contribute a guinea per week towards their expenses. Each of these institutions is supported entirely by voluntary contributions; and no one of them, I regret to say, is as well supported as it deserves.—Dr Radclyffe Hall.

The next General Meeting of Naturalists and Physicians in Germany will be held from the 15th to the 22nd of September at Königsberg, in the province of East Prussia.

APPOINTMENTS FOR THE WEEK.

Wednesday, September 5.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, September 6.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.

London Home.—2 p.m.

Friday, September 7.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, September 8.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, September 10.

Operations at the Royal Free Hospital, 2 p.m. Metropolitan Free Hospital, 2 p.m.

Tuesday, September 11.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

Dr ROBIE's communication has been received, and shall be inserted.

W. S.—1st. Certainly.—2nd. There is no restraining law.

Dr J. P.—By election of the Governors.

NEMO.—Our attention has been drawn to the subject.

AN L.R.C.P.—You are undoubtedly at liberty to use the title of Doctor, but you cannot style yourself M.D. A University Medical Doctor is not a Physician unless he be admitted a member of a College of Physicians, any more than an LL.D. or a D.C.L. is a lawyer without being duly registered in one of the Inns of Court. By courtesy Physicians are Doctors, and that is all that can be said about the matter. There is no prohibitory enactment.

Mr H. B., on the Stimulating System, received. We do not think that promiscuous stimulation has been beneficial in the practice of medicine. The same remark applies to promiscuous bloodletting. As Dr Spurgin would say, it is "judgment." A careful and vigilant helping of Nature's efforts, without any sort of charlatanism, will prove to be the most successful in practice. "Don't attempt to do too much," is the golden rule.

CHIRURGUS.—You could not charge for medicines in that capacity. The jury would consider whether it was optional with you to charge in one capacity or another.

Mr B. JAMESON is thanked.

Mr HEATH.—Yes.

JUVENIS.—A full account of the new regulations will soon be published.

Dr EDWARD B****.—We will give it consideration.

AN ASSISTANT.—We cannot afford you any assistance.

DETUR DIGNIORI is thanked for his remarks.

VERUS.—Enclosures received. The card is very discreditable.

THE COLNEY-HATCH ASYLUM.

To the Editor of the Medical Circular.

SIR,—At page 110 of the MEDICAL CIRCULAR of the 15th instant, it is stated that "the number of inmates confined in the Colney-Hatch Asylum is nearly two thousand; and the Medical Officers who are appointed to take charge of them are only two, exclusive of an Apothecary!"

Allow me to inform you that the latter part of the above statement is not correct. Instead of there being only *two* Medical Officers at Colney-Hatch Lunatic Asylum, there are—not including the Apothecary—*six*; three of whom are attached to the male, and three to the female department of the Asylum.—I am, Sir, &c.,

A MIDDLESEX MAGISTRATE.

London, August 29th, 1860.

(We were guided in our remarks by the return made to the 'Medical Directory' of 1860, in which the names of Messrs Tyerman and Marshall alone are mentioned. We are glad to know that there are six; but even this number is not sufficient, or the inspection must be indifferent.

ALPHA.—You can write to the Secretary of the Hospital for the Paralysed and Epileptic, in Queen square, Bloomsbury.

Mr JAMES L. KING.—Your communication on Hernia shall appear in our next number.

THE HAMPSHIRE ADVERTISER.—Received. We observe in this paper a lengthened report of a case of Emotional Paralysis, that was described by Dr Wiblin, of Southampton, at a meeting of the Medical and Chirurgical Society of that town. This report is precisely similar, as regards fulness of detail, to those that appear ordinarily in the Medical Journals. We should like to know how that report found its way into a local journal? If the Editor, on his own responsibility, deemed it proper to introduce a Medical report into the pages of his paper to gratify public curiosity, we have no right to complain, as it would simply show that the public in Southampton are beginning to take a deep interest in Medical Science, and must have already received considerable instruction in its more recondite mysteries. This would be a hopeful sign of modern enlightenment. If, on the contrary, it was inserted at the desire or by the sanction of Dr Wiblin, we can only condemn it as a most unusual mode of obtaining local notoriety. It is due to professional feeling and the obligations of professional etiquette that Dr Wiblin should repudiate any connection with this report, as we cannot believe that he was a party to its publication.

Flat Silver Watches—

Four Holes Jewelled and with true Sunk Seconds—£1 18s.

FLAT GOLD WATCHES—Eight Holes Jewelled, of a higher character, with White Dials and true Sunk Seconds—£6 6s.

The above are Sample Watches (Horizontal Principle) and such as within the large experience of this Old Established House we have never been able to offer at less than Three Guineas in Silver, and Ten Guineas in Gold Cases.—All warranted.—Per Post, 1s. extra.

Particularly suited for Students and Gentlemen of the Medical Profession.

ARNOLD, 59 and 60 Red Lion street, Holborn, London.

University College, London.

—FACULTY of MEDICINE.—SESSION 1860-61.

The SESSION will open on Monday, the 1st OCTOBER, at Three p.m.

The Courses of Lectures, &c., will commence on Tuesday, October 2.

Classes, in the order in which Lectures are delivered during the day:

WINTER TERM.

Anatomy—Professor Ellis, at Nine a.m.

Anatomy and Physiology—Professor Sharpey, M.D., F.R.S., at Ten a.m.

Chemistry—Professor Williamson, F.R.S., at Eleven a.m.

Comparative Anatomy—Professor Grant, M.D., F.R.S at Three p.m.

Surgery—Professor Erichsen, at Four p.m.

Practical Physiology and Histology—Professor Harley, M.D. (Wednesday) at Four p.m.

Medicine—Professor Walshe, M.D., at Five p.m.

Dental Surgery—Mr G. A. Ibbetson.

Practical Anatomy—The Pupils will be directed in their Studies during several hours daily by Professor Ellis, and Mr I. B. Lyon, Demonstrator.

SUMMER TERM.

Materia Medica—Professor Garrod, M.D., F.R.S.
Pathological Anatomy—Professor Jenner, M.D.
Medical Jurisprudence—Professor Harley, M.D.
Practical Chymistry—Professor Williamson, F.R.S.
Midwifery—Professor Murphy, M.D.
Palæozoology—Professor Grant, M.D., F.R.S.
Ophthalmic Medicine and Surgery—Professor T. Wharton Jones, F.R.S.
Botany—Professorship vacant.
Practical Instruction in Operative Surgery—John Marshall, F.R.S.
Analytical Chymistry—Professor Williamson throughout the Session.

Logic, French and German Languages, Natural Philosophy, Geology, and Mineralogy, according to announcement for the Faculty of Arts.

CLINICAL INSTRUCTION.

Hospital Practice daily throughout the year.
Physicians—Dr Walshe, Dr Garrod, Dr Jenner, Dr Hare.
Obstetric Physician—Dr Murphy.
Assistant-Physician—Dr Reynolds.
Surgeons—Mr Quain, F.R.S., Mr Erichsen, and Mr Marshall, F.R.S.
Consulting Surgeon to the Eye Infirmary—Mr Quain, F.R.S.
Ophthalmic Surgeon—Mr Wharton Jones.
Assistant-Surgeon—Mr Henry Thompson.
Dental Surgeon—Mr G. A. Ibbetson.

Medical Clinical Lectures, by Dr Walshe, Dr Garrod, and Dr Murphy; also by Dr Jenner, Professor of Clinical Medicine, whose special duty it is to train the Pupils in the practical study of disease, and who gives a series of lessons and examinations on the physical phenomena and diagnosis of disease to classes consisting of a limited number, and meeting at separate hours.

Surgical Clinical Lectures, especially by Mr Quain, and by Mr Erichsen.

Lectures on Ophthalmic Cases by Mr Wharton Jones.

Practical Instructions in the Application of Bandages and other Surgical Apparatus, by Mr Marshall.

Practical Pharmacy—Pupils are instructed in the Hospital Dispensary.

Prospectuses may be obtained at the office of the College.

Prizes.—Gold and Silver Medals for excellence in the examination at the close of the courses in most of the classes.

Liston Gold Medal for Clinical Surgery.

Dr Fellowes' Medals for Clinical Medicine, two gold and two silver.

Filliter Exhibition for proficiency in Pathological Anatomy, £30.

Longridge Exhibition for general proficiency in Medicine and Surgery, £40.

An Atkinson Morley Scholarship for the Promotion of the Study of Surgery, £45; tenable for three years.

Residence of Students.—Several of the Professors receive Students to reside with them, and in the office of the College there is kept a register of parties, unconnected with the College, who receive boarders into their families. Among these are several medical gentlemen. The register will afford information as to terms and other particulars.

JOHN E. ERICHSEN, Dean of the Faculty.
CHAS. C. ATKINSON, Secretary to the Council.

August, 1860.

The Lectures to the Classes of the Faculty of Arts will commence on Tuesday, 16th October.

The Junior School will open on Tuesday, the 25th of September.

St Mary's Hospital Medical

SCHOOL.—The WINTER SESSION will commence on MONDAY, OCTOBER 1st, at Eight o'clock p.m., with an INTRODUCTORY ADDRESS by Dr TYLER SMITH, after which a Conversazione will be held in the Museum.

It is a distinctive characteristic of St Mary's Hospital that its Medical Appointments are conferred upon the Pupils without additional fee. Three Resident Medical Officers are appointed for Twelve Months, and one, the Obstetric Officer, for Six Months, all of whom board free of every expense in the Hospital. The money-value of these five appointments far exceeds as many Scholarships of £50 each. Four non-Resident Medical Officers are also selected from the best-qualified Students.

Physicians—Dr Alderson, Dr Chambers, Dr Sibson, Dr Handfield Jones, Dr Sieveking, and Dr Markham.
Surgeons—Mr Coulson, Mr Lane, Mr Ure, Mr Spencer Smith, Mr Walton, and Mr James Lane.
Physician-Accoucheur—Dr Tyler Smith.
Ophthalmic Surgeon—Mr White Cooper.
Aural Surgeon—Mr Toynbee.
Surgeon-Dentist—Mr Sercombe.

LECTURES.—Clinical Medicine—Dr Alderson, Dr Chambers, and Dr Sibson. Clinical Surgery—Mr Coulson, Mr Lane, and Mr Ure. Medicine—Dr Chambers and Dr Sibson. Surgery—Mr Coulson and Mr Spencer Smith. Physiology and Morbid Anatomy—Dr Markham and Mr James Lane. Anatomy—Mr James Lane and Mr Gascoyen. Operations on the Dead Body—Mr Walton. Dissections—Mr Gascoyen and Mr Davy. Chemistry and Practical Chemistry—Mr Field. Midwifery—Dr Tyler Smith and Dr Grailly Hewitt. Materia Medica—Dr Sieveking. Botany—Dr Dresser. Medical Jurisprudence—Dr Sanderson. Ophthalmic Surgery—Mr White Cooper. Aural Surgery—Mr Toynbee. Dental Surgery—Mr Sercombe. Comparative Anatomy—Dr Grailly Hewitt. Natural Philosophy—Mr Smalley.

The In-Patients are visited daily by the Medical Officers, and the Out-Patients are also attended daily by the Physicians and Surgeons in charge of them. During the past year relief was afforded to 1549 In-Patients and to 13,727 Out-Patients. A Maternity Department is also attached to the Hospital.

Students are required to perform the duties of Clinical Clerks and Dressers, in each Session, during the last two years of their curriculum.

SCHOLARSHIP, PRIZES, ETC.—In addition to the Medical Appointments mentioned above, a Scholarship in Anatomy of the annual value of £25 is offered to the Students. Examinations for Prizes will take place at the end of each Session.

The Fee for the Hospital Practice and Lectures required by the College of Surgeons and Society of Apothecaries is £89 5s., which may be paid by instalments.

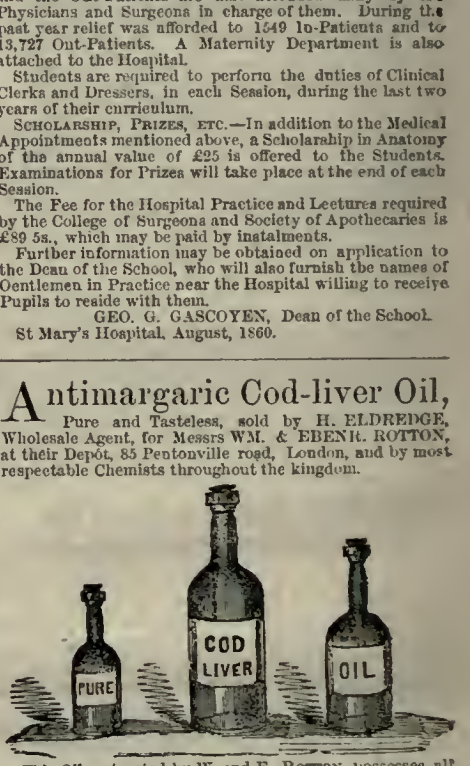
Further information may be obtained on application to the Dean of the School, who will also furnish the names of Gentlemen in Practice near the Hospital willing to receive Pupils to reside with them.

GEO. G. GASCOYEN, Dean of the School.

St Mary's Hospital, August, 1860.

Antimargaric Cod-liver Oil,

Pure and Tasteless, sold by H. ELDREDGE, Wholesale Agent, for Messrs WM. & EBENR. ROTTON, at their Depôt, 85 Pentonville road, London, and by most respectable Chemists throughout the kingdom.



This Oil, extracted by W. and E. ROTTON, possesses all the medicinal properties essential in cases of Consumption, Diseases of the Chest, Infantile Wasting, general Weakness, &c.; and for many ills the human frame is heir to, there is not its equal. In order to prove its superiority over every other, it has been subjected to the most scientific Analysis, as proved by Testimonials received from the following well-known Physicians:—WM. HERAPATH, F.C.S., of Bristol; JOHN POSTGATE, M.D.; Dr BELL FLETCHER, M.D.; D. W. CROMPTON, M.D.; WILLIAM SANDS COX, Senior Surgeon of the Queen's Hospital, Birmingham; and many others of equal eminence.

Dr SEPTIMUS GIBBON, A.B. & M.D., Medical Officer of Health, late Professor of Natural Philosophy at St Bartholomew's Hospital, Physician to the London Hospital, &c. &c., of No 3 Finsbury square, London, E.C., whose recent investigation under Government brought to light such an alarming extent of adulteration in articles of diet, writing expressly upon Messrs W. & E. ROTTON'S Antimargaric Cod-liver Oil, uses the following expressions:—

"I have carefully examined some bottles of Messrs W. ROTTON & SON'S Cod-liver Oil, and find them to be excellent samples of pure Oil. Besides answering admirably to the usual tests, it is free from the noxious and nauseous principles, Margaric Acid, &c., which so commonly render Cod-liver Oil not only unpalatable, but indigestible and injurious to the human stomach. By their mode of extracting and preparing this admirable remedy, I feel satisfied they have overcome the main obstacle to its more frequent and general use in medical practice."

The Antimargaric Oil is sold in pint bottles at 2s. 6d.; half-pint, 1s. 3d.; quarter-pints, 8d. Where a difficulty is found in obtaining it, write direct to the Depôt, when a case will be forwarded for the amount of 5s. or 10s., carriage free.

CLINICAL LECTURES.

ON THE TREATMENT OF FRACTURES IN CHILDREN.

DELIVERED AT THE HÔPITAL DES ENFANTS,

By M. GUERSANT.

(Continued from page 155.)

In fractures of the lower extremities, we seldom employ more than a simple roller bandage with three splints, using neither graduated compresses nor wadding, as in fractures of the humerus. The whole limb is first encircled with the bandage, on which it keeps up a regular pressure, and the splints are secured in a similar manner. The selection of these last should be made with great care, and the same attention should be paid lest they press injuriously on the bony eminences, as such pressure readily lends, in young subjects, to gangrene of the integuments. The outer splint should be long enough to extend beyond the ilium, and secured by a body-bandage, and so serve to fix the pelvis. By proceeding thus, you avoid the use of chaff-cushions, which in the case of young children soon get soiled. The splints and bandages being applied, you cover the whole with water-proof tissue, to prevent their being soiled by urine or fæces. In the case of grown children, however, I prefer the apparatus of Scultetus, and never neglect the small immediate splints recommended by Dupuytren. When applying these, the utmost care should be taken to bring into their exact position the fractured portions. When the leg is fractured, we apply equally three splints and a roller bandage, and take great care that the splint do not press against the crest of the tibia. When these fractures present no complication, and there is no reason to fear consecutive displacement, I prefer applying from the first a non-removable apparatus. Fractures of the patella are rare in children, and I do not remember to have seen more than three or four during the time I have been connected with this hospital; and I have nothing particular to say about their treatment. Fractures of the foot present the same indications as in the adult: as in these, we fix the foot against a wooden sole, and combat the traumatic symptoms with antiphlogistics. If the soft parts be divided, we usually have recourse to continued injections. In terminating this short review, I should add that our bandages are habitually kept wet with some such fluid as *eau blanche* or camphorated *eau-de-vie* at the time the bandages are applied.

I have next to insist on a practical recommendation of the highest importance; this, namely: when in children you renew the splints and bandages, the assistants must give their utmost attention to maintain the limb in a state of perfect immobility. With this precaution, we run no danger in inspecting the parts to which dressings are applied, and see that there are neither phlyctenæ nor excoriations, and that the coaptation is perfect. This active surveillance, in young subjects, should never be neglected; for, with such, the skin especially is soon injured by these appliances, and lesions of this sort are soon followed by such serious symptoms as erysipelas and deep sloughs, the copious suppuration of which may retard the consolidation of the fracture.

The next question is, When should the bandages be finally removed? In mere infants, twelve days suffice for consolidation. In children of two years, it is prudent to keep the limb in a state of immobility for a fortnight. When the patients are of the age of twelve or fourteen years, the apparatus must not, as a general rule, be removed before the twenty-fifth day. You thus see that there is a wide difference between fractures as they occur in different ages, in regard to the formation and progress of callus. It must not be supposed, however, that when the splints and bandages have been removed, no further care is required, and that the child may be left to pursue its amusements as before the accident. On the contrary, as regards the injured limb, much reserve and attention are necessary; and attention should be paid to it for at least six or eight weeks longer. I need not tell you that the progress of these fractures is not always so regular. It is not possible, where complications exist, to state the exact time required for a cure. Should there arise, for example, in the course of treatment, an attack of pneumonia or some grave fever, the failure of nutrition would retard consolidation. In all such cases the topical condition must be your guide in removing the appliances.

As regards complicated fractures, they demand the same cure, and are as uncertain in the time they require, as in adults. I shall only say that in children, *cæteris paribus*, complications are less serious. When there is serious mutilation, we employ, in preference to everything else, constant affusions, which are to be only gradually discontinued; for we dread the sudden discontinuance of cold applications to the wounds of our young patients. Every one of you can understand that it is always necessary to combat every cause that might retard consolidation. Thus, should the patient be rickety or scrofulous, you must prescribe such treatment as you believe most efficacious in those conditions. You frequently see me prescribe cod-liver oil and iodide of potassium to my young patients who have fractures. Where no general febrile reaction shows itself, children do all the better when their regimen is of a tonic kind.

You may often see rachitic children in whom consolidation takes place with rapidity; for in them the callus may be formed with as much promptitude as in those of the soundest constitution. But rachitism may, on the contrary, greatly retard the osseous reunion. This difference seems to me to depend on the degree of the rachitic affection. Should fracture occur in a rickety patient when the affection is in its wane, the formation of callus will be rapid—more rapid, perhaps, than it would be in a sound individual; while consolidation might be retarded indefinitely should the fracture take place when the disease is only in its first stage.

As in adults, so in children: you sometimes see fractures that do not reunite till you succeed in finding out the cause of non-union. For my part, one example only has occurred in my personal experience; and this patient, who now lies in the Salle St Pauline, No. 7, is still under your own eyes. This child has just undergone amputation for pseudarthrosis. You must suppose that many tentatives were made before having recourse to this extreme measure. Many practitioners before us have tried cauteries, setons, &c.; and in this case we made use of the rugine to the fractured extremities. These serious operations were followed by no unpleasant symptom, nor yet by any good result; and the patient and friends wished that amputation should now be had recourse to. All went off very well, and the child can now easily use an artificial limb.

ON THE PATHOLOGY OF THE SYMPATHETIC SYSTEM OF NERVES.

By JAMES RORIE, M.D., &c.

In the foregoing portions of this paper we have seen that, anatomically, the Sympathetic System is distributed to a much wider extent than was formerly supposed; and that although it is intimately connected with, yet it is altogether distinct from, the cerebro-spinal system of nerves. We have found it situated in close connection with all the so-called involuntary structures, especially those of digestion and circulation; and we have further seen how intimately it is related to all glandular organs.

Physiologically, we have found it, so to speak superintending all the functions of organic life. The whole extent of the mucous membrane, and all the glands connected therewith, we have seen to be regulated by these nerves; and all the vascular system we have found to be under their control. We have this portion of the nervous system, therefore, playing a very important part in the healthy animal economy, and naturally would expect the Pathology to be equally important; but when we consult pathological treatises, we find no mention of this system whatsoever, although we cannot suppose that derangement of so important a part of the animal frame can occur without external evidence, or that it can be destroyed without the health of the animal suffering.

Satisfied as to this imperfection in works on Pathology, I have carefully considered this subject, and beg to offer the following as the true Pathology of the Sympathetic System:—

On applying an irritant to any portion of the cerebro-spinal system, we find that an increase of the function of the organ or organs to which the nerves are distributed is induced; but if the irritation be long continued, or applied at first with great severity, that total loss of function, or, as it is termed *paralysis*, is the result. What has been found true with regard to the cerebro-spinal system, we shall see is equally applicable to the Sympathetic.

Now, paralysis of the Sympathetic System may occur in two ways. 1. It may be eccentric or local, from irritation applied to its peripheral distribution; or, 2. Centric or general, from agents acting on its great centres. It will, therefore, be under these divisions that we will now proceed to treat this subject.

1. *Eccentric Paralysis or Inflammation.*—Much has been written by Pathologists, since the introduction of the microscope, on the phenomena of what has been termed irritation, congestion, and inflammation; and from the facts elicited by microscopical observation, there has been deduced a great abundance of theoretical explanations. But no theory, so far as I am aware, has yet been brought forward with reference to the phenomena in connection with this morbid condition which embraces all the facts hitherto observed. It is not my intention, however, at present to revise and examine all that has been written on this subject, but to confine myself to what appears to me to be the true explanation of the phenomena of inflammation. We will first, however, consider what are the facts in connection with this morbid condition. On applying an irritant to the back of the hand, or on simply scratching the surface with the nail, a change in colour will be observed slowly to occur. In about three-quarters of a minute, the part so scratched will become gradually paler, till at last in about a minute it will appear quite white and bloodless. This paleness will then gradually diminish, when in about another minute the part will have regained its natural colour. Should the irritant, however, be more severe,—for example, should mustard be applied,—this paleness will not be observed over all the irritated surface, but only around the edge, the central part being of a dark-reddish hue, which requires a considerable time, sometimes hours, before it returns to its natural condition. This is the condition known to writers as congestion. This process may, however, continue a step farther,

and instead of slowly disappearing and leaving behind it no trace of its occurrence, the redness may continue, and an effusion take place of a clear fluid, the so-called *effusion of liquor sanguinis*. We have now reached what some writers have termed true *inflammation*.

Such are the appearances presented to the naked eye; let us now examine them more minutely as shown by the microscope, and for this purpose take what is usually employed, the web of a frog's foot. On examining this under a power of some 250 diameters, and applying a gentle irritant, we find the small vessels (some, as Lister, say the arteries alone, others the capillaries, but in all probability both, according to the means and power possessed by each) rapidly contracting, and pressing out the blood-corpuscles which they at the time may contain. On removing the irritant, the vessels now dilate to their former size, and the circulation goes on as formerly. Should the irritant, however, be long continued or more severely applied, this contraction of the vessels is followed by a more or less rapid dilatation, which may either pass off after a longer or shorter interval, or continue and give rise to stagnation of the blood, with occasional hæmorrhage. These two classes of phenomena are evidently analogous; the paleness and redness of the former corresponding respectively with the contraction and dilatation of the vessels of the latter.

Such are the facts observed in connection with these morbid changes; let us now consider what may be regarded as the correct theory of their cause.

Keeping in mind the circumstance that the capillaries are under the influence of the sympathetic nerves, and coupling this with the law already enunciated, that irritation first increases and then perverts nervous action, we at once comprehend the cause of these changes. The first effect of the application of an irritant acting on the nervous filaments distributed on the vessels, is an increase of their action, producing contraction, diminution of their calibre, and corresponding paleness of the skin. The irritation, however, continuing, or being applied with greater severity, produces, gradually in the former case, instantly in the latter, paralysis of the nerve fibres. The consequence of this paralysis is the loss of function of the arteries and capillaries, which, yielding to the force of the blood, dilate and give rise to the redness and so-called congestion. But, as we have shown while treating of the physiology of these nerves, this paralysis cannot continue long without a change occurring in the chemical character of the fluids with which they are in connection. We would, consequently, expect to find, and do find, important changes in the blood itself, and in the tissues supplied by it. The balance which in health exists between the blood and tissues now becomes destroyed, and exudation taking place into the latter, the process of inflammation may be said to be complete. We have thus a plain and simple solution of the phenomena of inflammatory action. *Congestion* and *Inflammation* may therefore be termed, the former *phenomena the result of temporary*, the latter *of permanent paralysis of the sympathetic nerves*.

As the following experiment is strongly corroborative of this view, I make no apology for inserting it here. In his paper in the 'Encyclopædia of Anatomy and Physiology,' already so often referred to, Drummond remarks that "Schiff found, when the upper two thoracic ganglia in the dog or rabbit were removed, that the animal did not survive the operation for more than thirty-four hours, the heart in the mean time pulsating very quickly and forcibly. On examination after death, the vessels of the pericardium were observed to be distended with blood, while a partly fluid, partly solid exudation surrounded the heart, forming in some parts adhesions between it and the pericardium."

Such, then, may be regarded the pathology of simple inflammation; but there are some secondary phenomena which require notice. Thus, should a gland be the part inflamed, its secretion will be found to undergo some important changes. It is scarcely, however, necessary to add, that these alterations in the secretion are essentially due to the changes in condition of the blood-vessels. They are, therefore, secondary in their character. To understand them, however, it is necessary to keep in view another established physiological law, namely, that an increased quantity of blood sent to tissues, in their natural condition, produces an increased growth in these tissues, or an increased secretion, if they be glandular organs, and *vice versâ*. Now, the first observable changes as regards secretion on the occurrence of inflammation, is a *gradual lessening* of the secretion, even to total cessation. Thus, to take as an example inflammation of the Schneiderian membrane. On the first application of cold, we have irritation of the nerves, and, in consequence, a state of contraction of the arteries and capillaries induced. Little blood being thus supplied to the membrane, the secretion lessens, and finally disappears. We have thus, in short, the first or dry stage of a catarrh. This condition, however, shortly passes off; the nerves becoming paralysed, the capillaries, in consequence, dilate, the blood continuing to circulate. The consequence of this is an increased growth and secretion. We have thus the second, or wet stage of the catarrh. Should, however, this process continue, the secretion totally ceases, and the part becomes swollen. Here the dilatation of the vessels still continues, but the blood no longer circulates; effusion takes place, and inflammation or permanent paralysis is established.

The increased growth taking place on the occurrence of congestion above referred to, is not, however, confined to glandular organs. Many changes, hitherto unexplained, must, I believe, be ascribed to this cause. We may here mention a few. A part kept in a state of irritation, as by occasional pressure, assumes the condition of congestion, and gives rise to increased growth. In this manner may be explained the formation of all so-called homologous growths, thickened epidermis, tumours, &c. By a chronic condition of this congestion, we may have produced many chronic skin diseases—eczema, icthyosis, &c. Again, this temporary paralysis occurring in the tongue gives rise to an increased development of epidermic scales, which assume the form known as "fur." In the same manner we have the false membrane formed in certain forms of dysmennorhœa.

Such are some examples of peripheral or eccentric paralysis of the Sympathetic System. In our next paper we will consider the second form in which paralysis of these nerves may occur—namely, general or centric paralysis, embracing the phenomena of Fevers, &c.

CASE OF STRANGULATED OBLIQUE INGUINAL HERNIA, WITH OPERATION.

By JAS. L. KING, Esq., Surgeon.

I wish to have the honour to bring the following case before your notice. Though it is not characterised by being of rare occurrence, yet it may be interesting to many of your readers, in a practical point of view.

On Friday, the 17th August, about eight p.m., I was summoned to attend T— M—, a robust young man, aged twenty-four, who was reported to be suffering severely from the effects of a "rupture." On arriving at the bedside of my patient, I found it to be so: there was a large scrotal hernia; he complained of much pain, was tossing to and fro in bed, and very anxious about his state.

On inquiry, I found that he was seized with symptoms of strangulation immediately after the bowel had descended into the scrotum, which accident had occurred about five hours previous from violent muscular exertion. He, however, believed that the hernia had commenced about ten years ago; but it was never very troublesome until six months since, when the bowel began to protrude at the external abdominal ring, and gave rise to some uneasiness. He was at that time recommended by a surgeon of the Royal Infirmary, Edinburgh, to wear a truss, and had done so ever afterwards. He also stated that about a fortnight previous to the 17th August, the "rupture" came down into the scrotum, after a violent muscular effort. No severe symptoms of strangulation at this time succeeded, though it gave rise to a considerable degree of uneasiness while it was down. He could not manage to replace it by his own manipulations, but, as is sometimes the case, it went up of its own accord, while he was lying upon his back, after having been down six hours. On the last occasion—that is, on the 17th August—the hernia also came down from violent exercise, and while he was wearing a truss; and he stated that from the time that the "rupture" occurred, it was attended with severe pain. The patient, indeed, up to the time that he was operated on, had all the symptoms resulting from a complete strangulation. The pulse at the first was about 112, beating full, and unresisting; it gradually became more wiry, and before the operation had greatly decreased in frequency. Vomiting was occasional from the first, and ultimately became more frequent, and the patient cried out from agonising pain, &c.

Suffice it to say, that I first put him under the influence of chloroform; tried taxis, but in vain; then warm bath; administered two enemata; employed chloroform and taxis in two hours afterwards, but to no purpose. After ordering cold applications to the scrotum, I delayed further interference until about three o'clock next morning. He still complained of excruciating pain; the scrotum was tense and immensely enlarged, and it could not be touched without causing great suffering. After repeated unsuccessful attempts to reduce the protruded viscus—from taxis, and other agents—I now resolved to lose no time in operating.

The patient having been put under the influence of chloroform, with the assistance of two men I commenced and completed the operation for the relief of stricture, in the usual manner. I with little difficulty cut down and reached the junction between the edge of the ring and protruded viscus. At this point, I cautiously opened a portion of the sac, and afterwards, by the use of a "director," carried the knife upwards, and severed part of the conjoined tendon, which I presumed to be the site of stricture. I next opened a larger portion of the sac, and at once endeavoured to replace the bowel; but I found that this still could not be managed. In truth, the bowel seemed constricted along the whole length of the inguinal canal. I had, therefore, to extend the incision for the relief of stricture, and ultimately succeeded in replacing a very large portion of bowel and omentum, and a considerable quantity of fluid was likewise evacuated from the sac. I closed the wound by ligatures, and applied a compress above the upper part of the wound.

The patient, after getting tinct. opii ℥j., slept well after the operation. On calling at eleven o'clock in the forenoon, he was asleep, and the pulse was about 100. He awoke in the afternoon, and complained of little pain.

On Sunday, 19th, he said that he had no complaint, though he had slept little on the night previous. The pulse had fallen to about 72, and was beating full and regular; he had slight thirst. I ordered him bitart. potassæ for a drink; and as a diet, sago or rice to be taken with milk. Sol. mur. morphiæ ℥ss. was to be taken at bed-time.

On Monday, 20th, he expressed himself as feeling quite well, having slept well on the previous night. Pulse had fallen to about 64; but up to this time his bowels had never been opened. I ordered him tinct. rhei com. ℥ss., and sodæ potass. tart. ℥j., mixed in a little water.

On Tuesday, 21st, he was much the same as on the day previous; the bowels had still never acted. I ordered him sulph. magnesiæ ℥ss., and towards evening he had two stools.

On Wednesday, 22nd, he continued to do well, and was ordered nourishing soup and wine as a diet. At that date, the wound at the lower part had united. At the time I write, the patient is wearing a pad and bandage over the wound, and is able to walk about a little with apparent ease and comfort.

I had some hope that in this case a radical cure might probably be effected. With that view, I took some pains to replace entirely the sac, and to constrict the canal as thoroughly as possible by taking a deep and secure hold of the tissues with the sutures that were employed to approximate the wound; but, of course, the result of the attempt to effect a radical cure, by whatever method practised, can only be tested some time after an

operation: and surely, in any case, the use of a truss must be employed as a suitable safeguard for some time afterwards.

This is a case—coming as it does within the usual domain of surgery—which presents to us nothing of special significance. Still, it is one of those cases which is suggestive of the importance of having recourse early to operative procedure, while it serves to furnish us with a suitable contrast to those cases that are usually admitted into hospital. It is too well known that numerous cases which reach the hospital exhibit to the surgeon the almost worthlessness of an operation, time having been unnecessarily squandered ere the patient has yet reached the operator, and therefore the patient is doomed not to recover.

Another thing worthy of remarking upon in an exculpatory way, has reference to the ignoring of bloodletting, and the non-performance of it before an operation is hazarded. It might be asserted that in this case the patient was young and vigorous, and if he had been bled, the inflammation could have been in a great measure subdued, and the hernia reduced. I am, however, rather positive, from the nature of the parts presented to view during the operation, that bleeding could have afforded little relief, and could never have enabled me to reduce the protruded viscus. And from what we know regarding the nature of the causes of peritonitis, one could not expect that this affection would thereby be warded off; nor can the ultimate recovery be aided by this remedial agent, except, perhaps, in rare instances before an operation, and occasionally, where one would be disposed to admit of its use, in the after-treatment of such cases.

Prestonpans, 31st August, 1860.

THE SPIRIT OF THE PERIODICALS.

Dr Brown Sequard's Lectures on *Paralysis of the Lower Extremities* are continued in the 'Lancet.' The special subject is the diagnosis and treatment of the several forms of Paraplegia as dependent upon different conditions of the spinal cord. The Lecturer observes:

"The most frequent cause of paralysis of the lower limbs is certainly an inflammation of the spinal cord. The cause of paraplegia which comes next as regards frequency is the white or non-inflammatory softening. This affection is produced in the spinal cord in a similar manner as in the brain—*i. e.*, in most cases as a consequence of an alteration of the bloodvessels, the walls of which do not allow that free interchange of matter between the nervous tissue and the blood, which constitutes nutrition—or probably in some cases as a consequence of interruption in the circulation of blood by the presence of a clot in a bloodvessel, or the pressure caused by a tumour upon a bloodvessel. I shall not say more as regards the history of the morbid anatomy of the spinal cord in this affection, as my object is only to study the symptoms and the treatment of the various forms of paraplegia.

"Usually patients attacked with the non-inflammatory softening of the spinal cord at first complain only of weakness. They gradually become weaker, although their general health may seem to be as good as ever. They feel the weakness especially at the knee and ankle joints; they find it very difficult to go up or down stairs, to go in or out of a carriage, and their gait becomes tottering, especially when they cannot direct their movements with the help of the sight. When lying down, if they see the lower limbs, they can move them pretty freely, but without force. After a time the paralysis becomes much more marked, and then sensibility in the whole length of the lower limbs and the power of the will over the bladder and the rectum are also found much diminished. There is no pain, or hardly any, in the spine or paralysed parts. Very rarely is the urine altered. The temperature of the lower limbs is often higher than it is in health, especially when the paralysis is complete or nearly so.

"We will refer to the preceding lectures for the diagnosis between the form of paraplegia depending upon the non-inflammatory softening of the spinal cord and the reflex paraplegia, or the forms of paraplegia due to myelitis, meningitis, or congestion of the spinal cord and its meninges. As regards the other forms of paraplegia, their diagnosis from that caused by softening of the cord will be indicated in another part of this lecture. We will merely say here that the absence of cramps, of pain in the spine and lower limbs, and of several other symptoms of disease of the spinal cord or its membranes, will help more for the diagnosis of the non-inflammatory softening of this nervous centre than the symptoms which we have described as existing in this affection.

"*Hæmorrhage in the Grey Matter of the Spinal Cord.*—Paraplegia due to this cause is characterised by the suddenness of its production, by a pain at the part of the spinal cord where the hæmorrhage occurs, owing, probably, to the distension of the posterior roots of the nerves in the grey cornua, by a pain in the spine after pressure upon it, and also by a pain in the parts of the body where are distributed the nerves originating from the part of the spinal cord which is the seat of the disease. The sphincters of the bladder and rectum are almost completely paralysed from the very first. It is not rare that an inflammation supervenes in the parts of the cord surrounding the clot, and then all the symptoms of myelitis occur.

"According to the seat and the extent of the hæmorrhage the symptoms vary extremely. If the amount of blood effused be very small, the symptoms may be very slight, and the patient may recover in a few months, as in a case recorded by Cruveilhier. If the amount of blood is considerable, it descends along the whole length of the central canal of the spinal cord, and also sometimes breaks through the grey cornua, especially the anterior ones. The loss of sensibility and of voluntary power is then complete, and the temperature of the paralysed limbs is increased. If the hæmorrhage is limited to one lateral half of the grey matter,—as in a most interesting case recorded by Monod, and in another by Mr Oré,—there is loss of movement in the side of the hæmorrhage, and loss of sensibility in the opposite side.

"It is a remarkable feature of paraplegia due to hæmorrhage in the grey matter of the spinal cord that a diminution of sensibility is always one of its first symptoms; and that when the whole of the grey matter is altered by the effused blood, the anæsthesia is complete.

"*Diagnosis of the Hæmorrhage in the Spinal Cord.*—The suddenness of the production of paraplegia is almost sufficient to show that it is due to effused blood, but it remains to decide whether the blood is in the tissue of the spinal cord, or in the vertebral canal, outside of this nervous centre. In this last case, there is more pain in a great extent of the spine than in the preceding; and also tetanic convulsions are not rare when the blood is effused outside of the spinal cord; while a hæmorrhage in the cord has never produced convulsions, so far as I know. Besides, there is more marked anæsthesia in cases of effusion of blood in the tissue of the spinal cord than outside of it.

"It is usually very easy to distinguish a hæmorrhage in the spinal cord from a white softening of this organ. The suddenness of the production of the paralysis and the existence of the pains will sufficiently characterise the first of these affections; and in those cases of almost sudden paraplegia, owing to softening, the absence of pains (in the spine, &c.,) will serve to distinguish this form of paraplegia from that due to a hæmorrhage. I need not say that these two affections—*i. e.*, softening and hæmorrhage—do not rarely co-exist. This co-existence will not be surprising to any one who knows that in the spinal cord, as well as in the brain, the same morbid conditions of bloodvessels is usually the cause of both these affections.

"*Prognosis of Paraplegia due to White Softening or Hæmorrhage in the Spinal Cord.*—The great indication for the prognosis in cases of softening or hæmorrhage in the spinal cord is the extent and degree of the paralysis. A softening limited to the lower part of the dorsal region of the spinal cord may admit of a very prolonged duration of life. A hæmorrhage is a more grave affection than a softening, because there is always a great chance of its being reproduced, and also because the blood effused may cause very extensive alterations. We do not know a single case of complete cure of paralysis of the lower limbs caused by softening or hæmorrhage in the spinal cord; but, as far as diagnosis not confirmed by autopsy may be relied on, we can say that we have seen many cases of non-inflammatory softening of the spinal cord arrested in their development, and, still more, that in five or six cases a very notable amelioration has taken place.

"*Treatment of Paraplegia due to White Softening of the Spinal Cord.*—The treatment of this affection ought to be pretty much the same as that of hemiplegia caused by a non-inflammatory softening of the brain. We will not enter here into the discussion of the various modes of treatment which have been proposed or employed in this last case; we will only mention the general plan of treatment we have employed with some appearance of success in many cases of softening of the spinal cord.

"1st. Iodide of potassium is the principal of the remedies that may be relied upon. We generally employ it in doses of five grains twice a day, mixed with nearly the same doses of sesquicarbonate of ammonia, in a decoction of cinchona bark, or an infusion of calumba or rhubarb. We insist upon the importance of taking this mixture before food in the morning and an hour before dinner, to avoid the decomposition of the iodide by the gastric juice and the setting free of the iodine, which sometimes takes place, and causes a gastric disturbance, erroneously attributed by some practitioners to the iodide itself.

"2nd. Besides the preceding remedy, we prescribe various tonics, such as iron and cinchona-bark wine.

"3rd. Strychnine may be employed with some profit in those cases where the paralysis is slight; but it must be remembered that, on account of the congestion produced by large doses of this alkaloid in the spinal cord, there would be danger in making use of it in cases where, the paralysis being complete, or nearly so, there is reason to think that the bloodvessels of the spinal cord are much altered, and that therefore a hæmorrhage might be the consequence of the action of strychnine. I need hardly say that those remedies which diminish the amount of blood in the spinal cord (such as belladonna, ergot of rye, &c.) should not be employed in this form of paraplegia.

"4th. Besides the use of some of the above remedies, I recommend, as an excellent means of improving the nutrition of the spinal cord, the daily use of the cold douche or the cold shower bath applied to the spine. Sea-bathing may also be of service.

"5th. The patient should lie down flat on his back at night; he should live upon the most nutritious food, drink wine and beer in a moderate quantity, and take as much exercise in the open air as possible, without, however, exhausting his diminished power of motion. Shampooing and galvanism may be applied with profit to the paralysed limb.

"*Treatment of Paraplegia due to Hæmorrhage in the Spinal Cord.*—The same rules are to be followed in cases of this kind of paralysis as in cases of softening of the spinal cord, with these slight differences: that, 1st, three doses of iodide of potassium, instead of two (of five grains each), ought to be given every day; 2nd, strychnine ought not to be employed; 3rd, constipation, lying down on the back, and all other causes of congestion of the spinal cord, should be carefully avoided.

"*Symptoms and Treatment of Paraplegia due to Hæmorrhage in the Vertebral Canal.*—A hæmorrhage between the spinal cord and its bony envelope is fortunately an event of rare occurrence. I have seen but one case of this kind of hæmorrhage, which proved fatal in less than two days. The blood is effused either between the pia mater and the arachnoid, or (more rarely) between the dura mater and the vertebræ. The first symptom is usually a pain extending along the spine from the seat of the hæmorrhage to the lower extremity of the vertebral canal. Almost immediately a complete paralysis of the lower limbs and very often tetanic convulsions appear. In almost all cases this hæmorrhage is rapidly fatal, either in consequence of its influence upon the circulation or respiration, or, indirectly, in consequence of an acute and extensive meningitis. Our object being here to study paraplegia in its chronic forms, we will not say more upon the symptoms of this affection.

"As regards the treatment of the hæmorrhage in the vertebral canal, we will only say—1st, that, at once, all the most active means usually employed in the various cases of visceral hæmorrhage should be made use of; 2nd, that the patient should be placed in bed on one side, and not on his back; 3rd, that pounded ice should be applied, in bladders, all along the spine; 4th, that if the patient survives several days, the same treatment as is above prescribed for cases of hæmorrhage in the grey matter should be employed."

Mr HILTON'S Lectures on *Pain* are also continued. We do not quote from them, as we have already given a copious extract in former numbers. Dr COOTE contributes to the same journal, remarks on a case of *Piarrhæmia accompanying Acute Diabetes Mellitus.* The case is interesting; we therefore give it.

"The pathology of fatty blood (piarrhæmia, pioxæmia, lipæmia) is still very uncertain. I avail myself of the following case (in itself of much interest) to point out, as nearly as may be, the present landmarks of our knowledge on this subject:—

"A. G——, aged twenty-one, was admitted into the Middlesex Hospital on Nov. 3rd, 1859, under the care of Dr Thompson. His history was as follows:—Six months before admission he had married, and, unfortunately, infected his wife with gonorrhœa. The ensuing domestic unhappiness occasioned a separation four months after marriage, at which time he considered himself in good health; but the circumstance preyed much upon his mind, and he became dull and low-spirited. Three weeks before admission, he first began to suffer from increased thirst, and at the same time noticed that he was voiding an unusual quantity of urine. From this period he had lost strength very rapidly. On admission, he was found to be in a state of alarming prostration, for which stimulants were freely administered, but without any good result. He continued to sink rapidly until the morning of the 5th of Nov., when he died. During his first twenty-four hours in the hospital he had passed five pints and a half of urine, acid, specific gravity 1031, and containing sugar.

"*Autopsy, eight hours after death.*—Weather damp. Rigor mortis considerable; body not at all emaciated; diabetic odour perceptible. On the brain being removed, about four ounces of pellucid serum were discovered at the base of the skull. Immediately upon exposure to the air, this fluid became opaque, and its surface was shortly covered with a thin milky pellicle. This was set aside for examination. The blood, as it escaped from the opened sinuses, was fluid, homogeneous, and of a dull-red colour, like raspberry cream; but, in a very few seconds, it separated itself into two distinct portions, the supernatant layer being of the colour and appearance of thick, white cream, the subjacent presenting the usual appearance of fluid venous blood. For the purpose of further examination, blood was collected from the sinuses of the brain, from the innominate vein and right ventricle, from the hepatic veins, and from the splenic vein. None could be obtained from the portal, nor from the superior mesenteric, veins.

"These specimens were allowed to repose, and were examined the next morning. The general results were as follows:—

"1. With the exception of a very small, non-adherent clot in the right ventricle, the blood was fluid in every part of the body examined.

"2. The supernatant creamy fluid was found in every specimen, except that from the splenic vein.

"Examined under the microscope, it appeared almost perfectly homogeneous. It contained no oil-globules; no cells (except a few scattered blood-corpuscles); and showed no trace of coagulated fibrin. Here and there were a few faint indications of amorphous granular matter, probably molecular albumen (?). It was wholly taken up by ether. The exact determination of its quantity was, unfortunately, not attainable; but it may be roughly estimated from the fact that, in a conical test-glass, the creamy layer occupied one-third of the whole.

"3. The subjacent layer presented the usual appearance of fluid venous blood. Neither in that from the splenic vein, nor in that from any other part, was there the least trace of a clot, even after forty-eight hours. It contained the usual proportion of red and white blood-corpuscles, apparently of a normal character.

"4. The reaction of the serum was neutral; it had no effect upon the colour of blue or of reddened litmus.

"5. A volatile alkali was driven off by heat, which restored the colour of reddened litmus. This reaction, however, was afforded much more readily by the splenic blood than by any of the other specimens.

"The remaining post-mortem appearances were as follows:—The brain (with medulla oblongata) weighed forty-nine ounces and a half. It was pale, and of extremely firm consistence, as though hardened in spirit. Under the microscope, however, its structure appeared to be perfectly normal. The muscular structure of the heart was of a pale rose-red colour. The right ventricle contained a very small, nearly colourless, non-adherent clot. All the valves were empty. The upper lobe of the right lung contsined a mass of crude yellow tubercle as large as an orange; this was surrounded by a distinct layer of pigment, and showed no signs of softening. The left lung was œdematous. The liver weighed sixty-eight ounces and a half; it was of an ashen-grey colour, and very friable; but microscopic examination showed no other change than an excess of fat in the liver-cells. The spleen (three ounces and a half) was small and pale; it contained one dark-coloured fibrinous deposit of the size of a hazel-nut. The mesenteric glands were not enlarged. The kidneys (each six ounces and a half) were large and flabby; the capsules non-adherent; the surface pale, faintly mottled; the structure coarsely striated. The supra-renal capsulea were quite healthy.

"This seems a well-marked case of diabetes mellitus, excited by psychical causes in a person of tuberculous constitution. It is not often that diabetes is distinctly referable to such a cause. Amongst the fifty-one cases recorded by Oppolzer and Heller, (Heller's Archiv., 1852, hft. xi.,) *fear* is assigned as the exciting cause in four instances. The extreme rapidity with which the disease ran its course is very remarkable. The ordinary symptoms of diabetes (thirst and polyuria) had existed for only three weeks, and that probably in no great degree, as the patient on admission was passing only five pints and a half of urine per diem. It is, of course, probable that the function of the liver had been disordered, and that the disease had been latent, for some time. But even thus it is impossible to assign to it a longer duration than two months; for at that period the man considered himself in perfect health. The most rapid case recorded by Oppolzer ran its course in three months. And this extreme rapidity serves to explain why, with such intense prostration, no emaciation was present; for (as we may observe in fever) it takes a much longer time to lose flesh than to lose strength.

"The creamy layer which formed on the surface of the blood in this case consisted obviously of free fat, for it was wholly taken up by ether. Such a pellicle on the surface of the serum is not uncommon, nor, indeed, wholly abnormal; but it is rare to meet with it, as in this instance, overlying uncoagulated blood. The only similar case, so far as I know, is that recorded by Leubuscher, (in Virchow's Arch., bd. 18, hft. 1, s. 124,) in which it is stated that "a portion of the white serum which stood in a test-glass, above the red portion of the blood, was shaken with ether, and almost entirely dissolved.

"In both these cases the peculiarity must have been due to the absence of coagulable fibrin. There is on record another case of fatty blood (Lecanu's) in which the fibrin is stated to have been entirely wanting; but no account is given of the appearance of the blood. In this and in some few other points, this case is exceptional. Otherwise it belongs to the extensive class of cases of 'milky serum,' under which head it may be more conveniently considered.

"I.—The *physical causes* of milky serum are two—free fat, and molecular albumen.

"In cases of leucæmia, also, the serum may be lactescent from an excess of colourless blood-corpuscles. But as this appearance is presented only by the *defibrinated* serum, leucæmic blood may be excluded from this inquiry.

"A. *Free fats.*—These belong (probably always) to the saponifiable group. In one case, indeed, (Lecanu's,) cholesterine is stated to have been present in the enormous proportion of 108 in 1000 parts. But as the saponifiable fats were also in excess (9 in 1000), the lactescence of the serum may have been due to these.

"The saponifiable fats of the blood (very variable in amount, but which may be roughly estimated at 1 in 1000) exist in the form of an emulsion with the free alkali of that fluid. Should they, however, be in excess of the emulsive power of the alkali, or should the alkali be (as in certain cases of disease) deficient, the fat must necessarily appear in a free state, and, on standing, rise like any other cream to the surface.

"The form in which it nearly always appears is that of oil-globules, as was first noticed by Hewson. In the present case it was perfectly homogeneous; and some similar instances have been observed by Professor Virchow. These are, however, exceptions to the rule.

"B. *Molecular albumen.*—That lactescence of serum is sometimes due to another cause than free fat, was first observed by John Hunter; but the fact was ignored or misapprehended until the more recent researches of Simon and Scherer, Buchanan, and R. D. Thomson, placed it beyond question. These chemists found that turbidity of serum was (in some cases) partly occasioned by the presence of a molecular substance, not soluble in ether, but presenting an albuminous reaction. To this substance Simon and Scherer gave, rather hastily, the title of molecular fibrin. It is now generally spoken of as molecular albumen.

"This substance forms no cream on the surface of the serum, but remains suspended in the fluid, thus rendering it permanently opaque, and so readily distinguishable from serum turbid from the presence of free fat alone. But frequently the two conditions are combined; the molecular albumen being associated with fat, either in a free state, and so rising to the surface of the turbid serum, or included in the substance of the albuminous molecules, from which it may be set free by chemical reagents.

"It is, indeed, very questionable whether lactescence of serum is ever due to molecular albumen alone. Some cases are, however, recorded by the late Dr Bostock, in which the milky serum is described as containing 'no proper oily matter,' although a creamy layer rose to the surface. It is possible that in these cases the albumen was floated by means of included fat. Another extremely obscure case, but perhaps referable to this category, is one which has been repeatedly, but unaccountably, cited as one of fatty blood. It is known as Caventon's case. In this the blood was permanently opaque; no cream appears to have formed on its surface; it was of neutral reaction, and coagulable by heat. A precipitate was thrown down by tincture of galls, but none by Hg. Cl_2, and very little by acids or alcohol. Caustic alkalies produced no effect upon it. The interpretation of this case is certainly difficult; but it seems most probable that the lactescence was due to more than one cause, and that one of the causes was the presence of albumen in some peculiar chemical state.

"With these exceptions, molecular albumen appears to be always accompanied by fatty disease of the blood."

An article by Mr BARNARD HOLT on *Allarton's Operation* is also contributed to the 'Lancet.' We will reproduce it next week.

Mr LAWSON reports two cases of *Conical Cornea* successfully treated by operation, which consisted

"In altering the shape of the pupil, by converting the natural circular aperture which is placed immediately behind the apex of the cone of the cornea into a slit, which may be made either vertical or horizontal as the surgeon may desire. The operation is performed by drawing the iris with a Tyrrell's hook through a small incision made at the extreme margin of the cornea by a broad needle, and then fixing it there by Mr Critchett's method of tying it with a piece of very fine thread. If a vertical pupil is desired, a portion of the iris is first drawn directly downwards, and there fastened; and at the expiration of eight or ten days, or when the eye has become perfectly quiet, a similar proceeding is adopted in the upward direction, and a slit-like pupil results. It becomes, as he there suggested, a matter of

experience to determine what alteration in the shape of the pupil is most conducive to improve vision in this class of cases."

Mr BRENT makes some observations in the same journal, on *Fatal Effects arising from Enlargement of the Thymus Gland in Children*, from which we will make a quotation next week.

The 'Medical Times and Gazette' opens with M. CLAUDE BERNARD's Lectures on *Experimental Pathology*. The present part contains some general observations introductory to the study of the various poisons. Dr GOODFELLOW continues his Lectures on *Bright's Disease;* and Mr SYMONDS, of Oxford, gives the following observations on the *Dressing of Stumps after Amputation:*

"The chances of quick union and a good stump undoubtedly depend, in a great measure, upon attention to a number of minute details in the dressing. Though the importance of such details has been generally acknowledged, they are too minute and various to have had much space allotted to their consideration in works on Surgery. The following observations on certain points connected with the dressing of stumps have no pretension whatever to originality. They are simply a statement of views, which both reason and experience have induced myself, and I believe many others, to adopt.

"SUTURES.—If we divide sutures into two great classes, viz. Metallic and non-Metallic, the majority of Surgeons of the present day—in amputation wounds, and most others where sutures are applicable—will probably be found to give preference to the former. In perfectly healthy tissues, union will generally take place so readily that the kind of suture to be used is not so much a matter for consideration; but when from any cause union is likely to be tardy, then it is a great desideratum to have one which may be kept in the wound for a comparatively long period, at the same time causing the minimum of irritation and lesion of the tissues through which it is passed. This seems to be the very advantage which the metallic suture possesses over one of any organic material.

"I must beg to acknowledge the experiments—so conclusive as to the relative merits of these two classes of suture—made some time ago under the direction of Professor Simpson, of Edinburgh (*vide* 'Medical Times and Gazette,' January 1, 1859).

"Assuming, therefore, the general inferiority of the organic suture, I beg to offer some observations on the relative merits of the two chief kinds of metallic suture—viz. the common wire, and the needle (or twisted) suture.

"With a view to test their relative value, repeated experiments were made by myself and Mr Gray, our House-Surgeon. In different patients, with different descriptions of wounds, the twisted suture was used side by side with the wire suture, and the result in almost every case was this—that, at the end of a given time, union was more advanced and more satisfactory at the points where the twisted suture was employed, than at the other points. These experiments appear to me to carry some weight; for, when two kinds of suture, inserted simultaneously, are left side by side in the same wound for an equal length of time, there can be little room for fallacy in one's estimate of their relative efficiency.

"The superiority of the needle to the wire is probably due to its greater firmness, enabling it to hold the edges of a wound in more exact apposition. The superiority of wire to thread, on the other hand, must be attributed to its inertness from non-absorption of surrounding fluids.

"An objection sometimes urged against the twisted suture is this—that often (in consequence of blood and lymph drying around the points of entrance and exit) its removal requires an amount of force which causes pain to the patient, as well as injury to the newly-formed adhesions. This evil may be prevented by a very simple precaution—well oiling the thread before it is twisted over the needle, and oiling it again (with a camel's-hair brush) once a day as long as the needle remains in. The needle may be removed without any pain, or any injurious traction on the tissues recently united.

"A very excellent kind of needle for the twisted suture is the common lance-pointed hare-lip needle, made by Weiss. It does not oxidise; it cuts easily, and is easily cut. I have suggested to Messrs Weiss, as a matter of economy, to have them made at least double their present length, since about a quarter of each one (the flattened extremity) has to be wasted.

"BANDAGING.—In ordinary cases is it advisable to bandage the stump? I think not. The practice of bandaging the stump immediately after amputation seems to be grounded on the following suppositions: That it prevents retraction and involuntary twitching of the divided muscles, and (according to some) the entrance of air or deleterious fluids into the veins. Now let us examine what truth there is in each of these hypotheses.

"1. As a matter of fact, does bandaging prevent muscular retraction? My own observation convinces me that it does not. I doubt whether it can even retard retraction. Consider the case of an amputation of the leg or thigh. The immediate and primary retraction of the divided muscles takes place probably in the course of a very few hours. In the operation the whole thickness of the muscles has been cut across, therefore the whole substance of the remaining muscle contracts. Now any one, who knows anything of the enormous strength of a single bunch of muscular fibres, will bear in mind how great must be the collective retractile force of the several muscles of a limb acting simultaneously. I am strongly inclined to think it is far too powerful to be counteracted by any amount of bandaging.

"Again, even if it were possible to effect this retraction, would it be desirable? Surely not; for until the retraction has taken place, and the muscles have become quiescent, I do not see how Nature's process of repair can commence.

"I have spoken of the immediate, primary retraction of the muscles. There is a subsequent, secondary retraction, which begins generally about the second or third week after the amputation, and lasts a considerable time. It shows itself by an alteration, to a variable extent, of the position of the cicatrix. In a thigh, for instance, the undue action of the flexors gradually pulls backwards the line of the cicatrix. Now, according to my experience, bandaging will no more prevent this secondary, than it will the primary retraction. The truth seems to be this,—that if a surgeon has left flap enough to allow for retraction, its occurrence will be no mishap; if he has not left enough, no amount of bandaging will remedy his error.

"2. As to the involuntary muscular twitching, causing the stump to start, this I have observed to occur just as much with a bandage as without one.

"3. There is one more hypothesis to be considered, viz., that bandaging the stump may prevent the entrance of air or deleterious fluids into the veins from the wound.

"This theory ignores the first principles of hydraulics, and all that we know of the physiology of the veins and the circulation. It assumes, first, that notwithstanding an atmospheric pressure of fifteen pounds to the square inch, the cut extremity of a vein may remain open, like a hollow tube, up to the nearest point where the current of blood begins. (We know that in certain localities a cut vein will remain open, its connections being such as to prevent its collapse; but of these we are not now speaking.) Secondly, it assumes that the vein aforesaid has a marvellous power of suction, whereby it is able to imbibe fluid from the wound, through this tubular portion, into the current of blood beyond.

"Now, if bandaging cannot answer any one of these ends, and has, further, the disadvantage of complicating the dressing, of concealing the stump from view, of getting constantly fouled by the discharge, of diminishing (when at all tight) the afflux of blood to a part which needs a very rich supply,—why bandage at all, unless œdema of the stump or some other complication render it necessary to do so?

"In my own practice, and that of my colleague Mr Hester, there have been at this Infirmary a considerable number of cases of amputation, in which primary union took place at all points, except those which gave exit to the ligatures, and good stumps resulted. In these the mode of dressing was as follows:—The wound having been secured with twisted sutures, a single layer of wet lint was placed loosely over the end of the stump, and kept constantly wetted for about a week; no other covering was applied. Then, as each suture was removed, a narrow strip of adhesive plaster was put to support the parts it had held in apposition, and changed as seldom as possible. No bandage or compress was used from first to last.

"PLASTER.—When it is desirable to support the edges of the wound with adhesive plaster, whatever may be the width of the strips towards their ends, I have found it better not to cut them more than half an inch broad at the part which is to be in contact with the wound. The advantages are—(1) That the condition of the wound in the intervals between the strips is thereby constantly open to inspection; (2) There is the smallest possible area of contact between wound and plaster,—a great advantage when the former happens to be irritable; (3) Free vent is left for discharge.

"The position of the strips of plaster should be changed occasionally; otherwise the intervening parts, from the unequal distribution of pressure, have a tendency to become unduly prominent. Attention to this will secure an evenly-rounded contour to the stump; neglect of it will do the reverse, however well the stump may have been cut. This leads me, lastly, to notice how much it is in the power of the dresser to mould a stump, by making constant, steady pressure (whether by plaster or other means) on any point. If in any case, to use Mr Paget's terse language, unremitting pressure will cause unrepaired absorption, more especially has it a tendency to do this in a part where new tissue is in process of formation."

Dr THOMAS SKINNER, of Liverpool, communicates an article to the same journal on *Deodorisation in Obstetric Medicine*. He says:

"Professor Simpson has shown that nearly 3,000 mothers die in childbed every year in England and Wales alone. He says: 'Among these 3,000 deaths, a comparatively small proportion only are the direct result of convulsions, hæmorrhage, rupture of the uterus, and the other more immediate or primary complications and accidents connected with parturition. The great majority of these deaths is produced by puerperal fever.'

"Dr Simpson here refers only to the deaths arising from puerperal fever, and not to the number of females attacked with the disease.

"Granting, that 3,000 females die in childbirth annually in England and Wales, that three-fourths of them—which is within the mark—die of puerperal fever alone, then that gives us 2,250 deaths annually from fever attending childbirth. Granting also that the mortality, in the absence of epidemic influence, ranges as high as 1 in 4, in round numbers this will present the fearful amount of at least 9,000 women attacked annually with puerperal fever in England and Wales alone. Among the causes of this fearful scourge on puerperal females, there is one which I think has not been sufficiently recognised. I allude to the injurious influence of the *post-partum* secretions and discharges of the puerperal female, and more particularly of those who have suffered from a tedious or obstructed labour, and who have been confined within the walls of Lying-in Hospitals.

Again:

"Without prosecuting this inquiry further for the present, I think that I am justified in concluding—1. That the decomposition of the organic tissues and fluids thrown off by the skin and vagina of the parturient female is to be looked upon as a fruitful source of puerperal fever and other *post-partum* febrile and inflammatory actions. 2. That if such decomposition can be regarded as an agent in the development of such conditions when patients are isolated, it is evident that it must be a much more active cause in Lying-in Hospitals, where the emanations from the patients are more likely to accumulate, and lead to the generation of a peculiar miasmal condition of the air of a ward. 3. That, as the decomposition of organic matter gives rise to fetid odours, such odours in turn become sufficient evidence of decomposition and its dangers. 4. If the premises be true, then deodorisation of the lochia by an agent which stops decomposition promises fair to become a prophylactic of no mean value of puerperal fever and such-like *post-partum* accidents.

Any practicable means which, without much trouble and at a cheap rate, will safely and effectually relieve the parturient female of all disagreeable smell about her apartment, bed, or person; which will make the patient more comfortable, and less loathsome to herself and friends; and which will at the same time assist in preventing the generation of miasma, or lessen the danger from the poisonous influences associated with putrid or morbid effluvia,—must be hailed as a great addition to the Materia Medica of Obstetric Medicine. Such an agent, I think, we have in the oil of tar."

Dr FIGG also contributes a paper on *Turning in all Cases of Labour*. The Author discourses extensively about the laws of Nature, Neapolitan scenery, the Adamic age, the odours of Cashmere, and the Prophet Jeremiah: the special subject to be treated of is reserved for a future paper. Dr HENRY COOPER ROSE contributes the following case of *Poisoning by Alcohol* in a child three years of age:

"At 11 a.m. on May 28th, last, I was hastily summoned to attend a little boy three years of age, who was stated to have drunk a quartern of raw rum, and also an uncertain quantity of gin, supposed to be about ℥ij. He was heard to fall heavily on an upper floor, and was found lying on his face, with his nose bleeding, in a state of insensibility.

"On my arrival, I found him lying in a woman's lap in a comatose condition. There was no stertor. The pulse moderately full, but slow. Pupils contracted to a point; face flushed. He smelt strongly of spirits. Skin warm.

"I administered an emetic of zinci sulph., with which I was provided, and tickled the fauces with a feather. This acted copiously, and a large quantity of semi-fluid matter was vomited, smelling strongly of spirits. After a few minutes had elapsed I gave another emetic of mustard, which also induced vomiting of the same character.

"On the arrival of the stomach-pump, which I had sent for, I endeavoured to introduce the tube, but was resisted by the child; and feeling pretty confident that the stomach was empty, and finding consciousness to a certain degree returning, as indicated by the resistance made to the introduction of the tube, I deemed it unadvisable to risk injury to the fauces, and desisted. The child made several attempts to vomit, bringing up small quantities of thick mucus.

"At this period, being about an hour from the time that I first saw the child, he could be roused to a certain degree of consciousness by flapping with the wet corner of a towel, but could not speak or notice any one. The pupils, which were contracted, were now largely dilated. There had been complete freedom from stertor, although the breathing was heavy. The pulse was slow, but not so full. After being in attendance for nearly two hours, and observing a decided improvement in the child's condition, I left for a time, giving directions for the head to be kept cool, stating my intention of revisiting him shortly. In little less than half-an-hour a messenger was despatched to my residence to tell me that the child had had a convulsion; and, immediately after, a second messenger arrived, stating that another convulsion had occurred, and that the child was dead. The bowels had acted twice, and he had passed water while in a state of stupor.

"*Post-mortem Appearances, eighteen hours after Death.*—Surface pale; considerable rigor mortis. The stomach contained ℥vj to ℥j of thick mucoid matter, mixed with some alimentive substances resembling bread. There was a slight smell of spirits. Mucous membrane injected over the whole of the cardiac extremity, as also in the lesser curvature; otherwise healthy. Lungs congested posteriorly from gravitation. Heart natural: left side full, right side empty; the blood was fluid. The brain and its membranes were intensely congested, blood oozing out at every incision. A small quantity of fluid in the right lateral ventricle. Choroid plexus gorged with blood. All the viscera healthy.

"*Remarks.*—There are two or three points of interest in this case. In the first place, it is a very unusual circumstance that a child of such tender age should, *con amore*, drink off so large a quantity of raw spirit. It is important in a medico-legal point of view. Physiologically, it is interesting to observe the action of the alcohol upon the condition of the pupils: at first, under the immediate stimulus of the spirit, such filaments of the third nerve as supply the iris through the ophthalmic ganglion were irritated so as to produce spasmodic contraction; and this fact may possibly be taken in similar cases as an indication that the spirit has been recently swallowed; for as soon as the narcotic influence was in full action, the pupils became dilated in the extreme, and remained so till death. Convulsions are by no means a common result of alcoholic poisoning, except in the young. 'Orfila makes their absence a ground of diagnosis between poisoning by alcohol and by opium, and Dr Ogston only observed them twice out of many cases; the subjects in these two instances were young.' The time that elapsed between the taking of the spirit and the state of insensibility could not have been longer, from the evidence of two women, than ten minutes; and from that time till death, about two hours."

We extract the following *Remarks on Sunstroke*, by Dr EDWARD SMITH, which appeared in the 'Medical Times and Gazette' of the 1st inst.:

"In the 'Medical Times and Gazette' for July 28th, 1860, p. 76, there is an interesting report by Assistant-Surgeon R. Chapple on several cases of sun-stroke; and in a former number similar reports of equal value appeared from the pen of Deputy-Inspector of Hospitals Mr Longmore. Sir Ranald Martin has also, at various times, published observations upon the same subject. In each of those there is mentioned a characteristic of the disease to which I desire to draw attention, viz., the heat and dryness of skin which is observed both in the early and in the later hours of the attack. Mr Chapple is so impressed with this fact, that on three occasions in a paragraph he makes use of the expression 'the skin was intensely hot and dry;' and in showing his estimate of the connection of this phenomenon he also remarks, 'I have wrapped patients in wet sheets, by which means I thought I might get the skin to act, but without benefit.' Hence all agree in the fact that the skin has ceased to act as the great refrigerator of the body.

"The temperature of the air in the shade, as mentioned by Mr Chapple, was 106° and 110° at 4 a.m., and 97° at 10 p.m.; that is to say, a temperature at least equal to that which is the almost unvarying standard of the internal parts of the body in a state of health. Hence, if the body had been mere dead matter, it would have obtained, by radiation throughout the whole day, a temperature equal to that of the living organism in its normal state; but, being a living body in which conversion of nutriment must take place and heat be generated, it is evident that at all times of the day and night there would be an excess of heat. This excess, already shown, could not be removed by radiation; and as the function of the skin had ceased, and the respiratory function was lessened in activity, it could not be lessened by absorption, as occurs when a large amount of sensible heat is rendered latent by the act of converting the fluids of the body into vapour in the process of perspiration.

"I do not purpose to discuss the physical effects upon the system of this excess of heat, since we have not much precise knowledge upon the subject; but it is evident that in the absence of this refrigeration at the surface, the volume of the blood will be increased on the law of expansion of fluids by heat. There will also be oppression of the heart, from the resistance offered to the current of the blood in the capillaries; and with the lessening respiration, there must be accumulation of blood in the lungs. The general symptoms at the period of attack show a state of oppression of all vital actions, and near the termination they are those of exhaustion, or, as Mr Chapple states, 'the patients die worn out.' It is also clear that with the suppression of the great outlet for water, it will be impossible to give food and fluids internally, unless, indeed, as in some favourable cases, the kidneys double their activity; for otherwise the fluid either would not gain admission into the circulatory system, or the vessels would become yet further congested.

"The point upon which I wish to fix the attention of those who have charge of men exposed to these dangers, is the paramount importance of maintaining or of restoring a free amount of action of the skin, and of pointing out some methods of effecting that. It will be borne in mind, that such a condition is as essential when the external temperature is just under that of the standard temperature of the body in health, as when it is above the standard; for in either case the effects of the excess of heat must be present.

"When the skin is acting freely, the fluid converted into vapour carries off from the body 1000 times as much heat as it held when in the state of a fluid; and hence there is a most potent refrigerating power ever acting and needing regulation; and so perfect is it, that it is sufficient to carry off any amount of heat which can be generated in natural conditions, provided the supply of fluid to the blood and the activity of the skin be both free, as is shown by the endurance of dry, hot baths, at 150° to 200° of temperature, for considerable periods. The freedom with which the perspiration occurs, reduces the volume of the blood, and thereby necessitates a call for a further supply of fluid from without; and the heart and lungs being kept free from any undue oppression, duly perform their functions. The heart, however, must act rapidly, so as to convey sufficient fluid to the skin; and the more so that, as I have shown in the 'Philosophical Transactions' for 1859, and elsewhere, the rate of respiration is disproportionably lessened with increase of temperature, and thereby there is a constant tendency to accumulation of blood in the lungs.

"As, therefore, it is of the first moment to maintain a due activity of the skin under the conditions of exposure to great heat, I am desirous to mention the various kinds of foods which in my experiments have evinced the power to aid or retard the activity of that organ, for they must have a daily influence in modifying the liability to the effects of excess of heat.

"Nearly all ordinary foods lessen the activity of the skin in the primary processes of their digestion, as is shown by the heat and dryness of the skin at that time: such are animal foods, including flesh, fat, and milk; all kinds of beverages classed under the denomination of alcohols, and also coffee. The substances used in food which increase the action of the skin are tea and sugar.

"Of the former, or those which lessen the action of the skin, no doubt alcohols should occupy the first place. In this respect strong spirits have a more powerful action than wines or beers; and it is highly probable that raw and inferior kinds of spirits are also more powerful than finer and purer spirits. I have not found any exception whatever to this statement; for even rum, which acts in a different manner upon the respiration, agrees with all its congeners in this—all alike make, or tend to make, the skin hot and dry. But next to these substances coffee must certainly be placed, and particularly if it be drunk without sugar, or with the addition of milk or brandy. Meat and fats have, perhaps, less influence in this direction, but they nevertheless are powerful agents. Hence it is manifest that although some of these must be ranked among the necessaries of life, and cannot be altogether dispensed with in any dietary, the use of them should be strictly limited when the body is exposed to the evils of excess of heat. In accordance with this statement, it is well known that spirits are most destructive, and that the natives of hot climates eschew them, and do not indulge largely in milk or animal food. If they take fat, moreover, it is, perhaps, not very largely, and it is always associated with starchy food, which exerts very little influence over the activity of the skin. It is a very doubtful point as to the propriety of the Government introducing into India the strong ales of this country under conditions so diverse from those in which we drink them; and although they are less powerful in the direction now referred to than stronger alcohols, they must usually be injurious.

"With very moderate living, it is clear that tea should be regarded as an indispensable adjunct, and that coffee should be excluded at the hot season and during exposure to intense heat, except by the comparative few in whom the skin is usually too active. It should, for the purpose of increasing the action of the skin, be taken without milk or cream in very moderate doses, and very frequently. Indeed, under such conditions it should be the constant beverage throughout the day, but not drunk in large quantities at

a time. It appears to me that the importance of this agent is not by any means so well understood as it ought to be, and that it would be to the great advantage of our soldiers if the Government were duly informed as to its value, and even its necessity.

"I would just add a word in reference to the treatment of cases of sun-stroke. It is clear that these cases must be regarded as due essentially to excess of heat in the body, and that independent of exposure to the direct rays of the sun, or even to very exceptionably high degrees of temperature. The first remedy usually applied is that of water, which, although of lower temperature than that of the body, cannot be called cold, but its free use has been of the utmost service in warding off threatened attacks. In the attacks, however, neither the cold douche nor the wet sheet has commonly been efficacious, as Mr Chapple has well shown.

"As the greatest of all desiderata is the return of the action of the skin, I venture to hint that beyond a certain duration the direct application of the cool water is likely to be injurious by interfering with any attempts to increase the action; for if remedies be given which increase or tend to increase perspiration, their action will certainly be hindered by the application of anything to the skin which has a lower temperature than that of the body.

"In this condition I very earnestly commend the use of good tea, in doses of twenty-five grains every quarter of an hour, given in a weak infusion of about three to six ounces, and of a temperature but little below that of the body. The action of tea, beyond that on the skin already referred to, is directly to increase the vital action through the medium of the nervous system; and it has a powerful and sustained effect in increasing the respiratory functions. Hence it meets so far as it can three of the most urgent wants, viz., cooling of the body, removal of the listlessness and oppression, and increase of the respiratory action—it being clearly understood that respiration has in itself a great tendency to lessen the temperature of the body. Diffusible stimulants, as ammonia, have been found somewhat useful, and that no doubt from their tendency to act through the skin. I have also shown that the addition of alkalies to tea increases the action of the latter substance upon the skin, and hence it would be well to add neutral acetate of ammonia or acetate of potass to each dose of the tea.

"Mr Chapple and others refer to the vomiting which takes place late in the attack, and I venture to ask if it would not be of great value to induce this by ipecacuanha early; for in addition to the good effect of removing matters which may tend to restrain the action of the skin, the act of vomiting tends most powerfully, as we know, to induce perspiration. I do not think the use of an emetic is contra-indicated because there is lessened vital action at the commencement of the attack, for that early condition is, as already mentioned, one of oppression, and not of exhaustion.

"I further venture, but with great deference, to recommend the use of warm water (if during the attack the cold douche has failed) of a degree about that of the normal temperature of the body, for its efficacy in tending to induce perspiration is well established. I do not think that the addition of warm water to the body suffering from excess of heat is contra-indicated, provided the degree of warmth be not greater than the natural heat of the body, and the drinking of tepid water largely in the early stage must have a right tendency, on the principles already laid down.

"In this communication I have not entered into any question but that which I desire very earnestly to commend to the consideration of those who have charge of these very anxious and too often fatal cases."

The 'Dublin Medical Press' contains the following observations, by Dr JACOB, on an *Ulcer* (the Rodent Ulcer) *which attacks the Eyelids and other parts of the Face:*

"The characteristic features of this disease are the extraordinary slowness of its progress, the peculiar condition of the edges and surface of the ulcer, the comparatively inconsiderable suffering produced by it, its incurable nature unless by extirpation, and its not contaminating the neighbouring lymphatic glands. The slowness with which this disease proceeds is very remarkable; of three cases which have come under my observation, one had existed for four years, and now presents no remarkable difference when compared with the drawing of it which was executed six months ago: the eyeball, exposed and dissected out as it has been by the ulceration, remains precisely in the same state, and the edges occupy the same situation as at that period. In another case, now also under my observation, the patient, an unmarried woman, aged fifty-five, states, that the disease has existed for twenty-three years without having ever healed; her eyeball also has been exposed by the ulceration for nearly a year, and has not yet been totally destroyed. In the third case, that of a gentleman about sixty years of age, the disease existed for about nine years previous to his death, which took place from a different cause.

"The sufferings of persons labouring under this disease do not appear to be very acute; there is no lancinating pain, and the principal distress appears to arise from the exposure, by ulceration of nerves or other highly sensitive parts. In the examples which I have met, the disease at the worst period did not incapacitate the patients from following their usual occupations; the gentleman to whom I have alluded was cheerful, and enjoyed the comforts of social life after the disease had made the most deplorable ravages.

"In two of those three cases, I have been unable to ascertain with certainty the nature of the disease at its commencement; whether the ulceration was preceded by tubercle, encysted tumour, or wart. The account given by the patient from whom the drawing has been made, a poor woman, aged fifty, is that it arose from a blow, and commenced on the temple at a short distance from the external angle of the eye. The other woman, whose disease has existed for twenty-three years, says that it was preceded by 'a kernel under the skin over the eyebrow, which was not rough like a wart, and which existed for two or three years before it came to a head, when she picked it, after which it never healed.' I quote her own words: it was probably an encysted tumour. In the gentleman's case the disease commenced in an old cicatrix, the consequence of confluent small-pox; it was at the inner angle of the eye, and constantly moistened by the tears, which could not escape into the nose, the *puncta* being closed.

"This disease may be observed under two very different conditions, either in a state of ulceration, or in a fixed state, in which no progress is made toward healing. In this latter condition the parts present the following appearances: the edges are elevated, smooth and glossy, with a serpentine outline, and are occasionally formed into a range of small tubercles or elevations; the skin in the vicinity is not thickened or discoloured. The part within the edges is in some places a perfectly smooth, vascular, secreting surface, having veins of considerable size ramifying over it; which veins occasionally give way, causing slight hæmorrhage: in other places the surface appears covered by florid, healthy-looking granulations, firm in texture, and remaining unchanged in size and form for a great length of time. The surface sometimes even heals over in patches, which are hard, smooth, and marked with the venous ramifications to which I have alluded. This healing may take place on any part of the surface, whatever may be the original structure: in the case from which I have had a drawing made, the eyeball itself, denuded as it is by ulceration, is partially cicatrized over. When the ulceration commences, it proceeds slowly, cutting away all parts indiscriminately which may be in the direction in which it spreads: the surface in this state is not so florid, and presents none of the glistening or granulated appearance above noticed: the pain is generally greater at this period. It appears also that there is a tendency to reparation, exclusive of the cicatrization which I have mentioned: there is a deposition of new material, a filling up, in certain places, which gives a uniformity to the surface, which should otherwise be very irregular, from the nature of the parts destroyed. When the disease extends to the bones, they sometimes exfoliate in scales of small size; but more generally they are destroyed, as the soft parts, by an ulcerative process. The discharge from the surface is not of the description called by surgeons unhealthy or sanious, but yellow, and of proper consistence; neither is there more fœtor than from the healthiest sore, if the parts be kept perfectly clean, and be dressed frequently. There is no fungous growth, nor indeed any elevation, except at the edges, as already noticed, and even this is sometimes very inconsiderable. There is no considerable bleeding from the surface; and when it does occur, it arises from the superficial veins giving way, and not from sloughing or ulceration opening vessels: sometimes the surface assumes a dark, gangrenous appearance, which I have found to arise from the effusion of blood beneath. I have not observed that the lymphatic glands were in the slightest degree contaminated, the disease being altogether extended by ulceration from the point from whence it commences.

"After the preceding description, it is scarcely necessary to state additional arguments to prove that the disease is peculiar in its nature, and not to be confounded with genuine *carcinoma*, or with the disease called *lupus* or *noli me tangere*. From the former it is distinguished by the absence of lancinating pain, fungous growth, fœtor, slough, hæmorrhage, or contamination of lymphatics; from the latter, by the absence of the furfuraceous scabs and inflamed margins, as well as by the general appearance of the ulcer, its progress and history. It is equally distinct from the ulcer with cauliflower-like fungous growth, which occasionally attacks old cicatrices.

"It remains to be determined whether this disease can be removed by any other means than the knife or powerful escharotics; and from the experience I have had in those cases, I am inclined to conclude that it bids defiance to all remedies short of extirpation. I have tried, internally, alterative mercurials, antimony, sarsaparilla, acids, cicuta, arsenic, iron, and other remedies; and locally, simple and compound poultices, ointments, and washes, containing mercury, lead, zinc, copper, arsenic, sulphur, tar, cicuta, opium, belladonna, nitrate of silver, and acids, without arresting for a moment the progress of the disease. I have, indeed, observed that one of those cases which is completely neglected, and left without any other dressing than a piece of rag, is slower in its progress than another which has had all the resources of surgery exhausted upon it. The success even of powerful escharotics is doubtful. Mary Sherlock, the old woman who has laboured under this disease for twenty-three years, and who is now in the Incurable Hospital, says that 'a burning cancer plaster' was applied several times, seventeen years ago, and she has lately had the arsenical composition called Plunkett's powder applied without any good effect. The gentleman to whose case I have alluded, had the sore healed, when it was very small, by the free application of lunar caustic, under the care of Mr. Travers: it, however, broke out again, and spread without interruption, until it destroyed the lids and globe of the eye; under which circumstances he, in despair, submitted himself to a popular charlatan, who, bold and fearless from ignorance, gave a full trial to escharotics: he repeatedly applied what I understood to have been a solution of muriate of mercury in strong nitric acid, and in a short time excavated a hideous cavern, extending from the orbitar plate of the frontal bone above, to the floor of the maxillary sinus below, and from the ear on the outside, to the septum narium within; yet the unfortunate gentleman survived, but the disease preserved in every respect its original character. Mr. Colles, however, tells me, that in a case which came under his care before the disease had extended to the lids, he succeeded in establishing a permanent cure by the application of a powerful escharotic, covering up the eye during the operation of the remedy with gold-beater's leaf.

"Such is the information which I have to communicate respecting this malady: I offer it with the hope that surgeons who have met with similar examples may be induced to give the result of their experience respecting it. Sufficient has, however, been ascertained to prove, that when the disease exists in a situation which admits of it, the sooner it is completely extirpated by the knife, or the actual or potential cautery, the better chance is afforded the patient of relief from a most distressing and fatal malady."

TRANSFUSION AFTER EXHAUSTING SUPPURATION.

Dr Neudörfer, of Verona, gives here an account of some trials he has made of the efficacy of transfusion in some cases in which exhausting suppuration rendered death imminent. The subjects were soldiers, who had suffered from wounds in the late Italian war. He has tried the practice in six cases, and always found a remarkable temporary improvement result. The pulse regained some force, refreshing sleep (unprocurable heretofore by opiates) was obtained, the appetite increased, and the severity of the pain diminished. This improvement continued for from five to eight days, when the former unfavourable condition recurred, and death resulted within three weeks.—Froriep's 'Notizen,' Band 1, No. 22.

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

THE MEDICAL CIRCULAR.

WEDNESDAY, SEPTEMBER 12, 1860.

THE GRAPE AND WHEY CURES.

Every production of Nature and every imagination of man have been enlisted to present some new form of quackery to the world. No sooner is one pretension on the wane than another lifts its shining light. There is no fear that credulity will want objects for its faith, for they are always changing and always new: thus, hope is kept alive and quackery flourishess. In these peaceable days, the charlatan is our only hero; and although there are many of the brood, the public is ever on the search for a new candidate. As Byron says with a fresh circumstance,

"A quack is wanted; an uncommon want,
When every year and month brings forth a new one,
Till, after cloying the gazettes with cant,
The age has found that it has not the true one."

Within these few weeks, the British public has been made acquainted with a new production of this rank soil. It has not yet, happily, been imported into this country; but in Germany it flourishes with great vigour, and commands a large body of admirers. This new mode of medication is called the Grape-cure,—a kind of antithesis to the Water-cure, of which the Teetotallers have the practical monopoly in this country. Whether the proprietors of French and German vineyards felt alarmed at the extraordinary success of Mr Gough, and were apprehensive of the enactment of a Maine Liquor Law; or whether they feared that Dr Todd's heroic administration of the alcoholic juice of the grape was likely to be followed by a reaction dangerous to their interests; or whether they were really animated by philanthropic motives, and, lamenting the immoral uses to which the grape was applied, were desirous of reviving among mankind a taste for its flavour as presented by the hand of Nature to the unsophisticated gustatory organs of our Adamic progenitor,—history does not inform us; and we are content to know that, in the opinion of a considerable number of French and German valetudinarians, the unfermented juice of the grape is deemed an infallible cure for many of the maladies to which flesh is heir.

Associated with the Grape-cure is another—the Whey-cure. The latter is not very new; it is as old as the Tartars; was once popular in England, and has been among all milk-drinking nations a panacea for the ills of mortality.

First, however, of the Grape-cure, which is practised in the South of France and Switzerland. Dr Carrière has written a book about it, and we are informed upon the authority of this gentleman that some patients consume as many as six or eight pounds of grapes daily. It is an essential part of the treatment that the grapes shall be eaten in the vineyard, where the invalid's

"direst task
Is on sunny slopes to bask,
To shake the berries from the bough,
And catch them tumbling on his brow."

What a delightful occupation for a valetudinarian! Can anything be imagined more poetical or luxurious? O! Mr Prince, does not your prophetic soul suggest to you that the Agapemone will be incomplete unless the Grape-cure become one of its attractions?

We are told that at Celles

"The Grape-cure consists in eating every day from three to five pounds of ripe grapes. The patient takes in the morning a pound fasting, carefully avoiding swallowing either the skin or stones; and yet at Celles, this precaution, advisable at Fontainebleau and on the banks of the Rhine, is unnecessary, for the pellicle of the grape is of extreme tenuity, and instead of being acid may be reproached with excessive sweetness.

"Two hours later, the same dose of grapes is repeated. Dinner at twelve, of beef or mutton, roasted or otherwise (Ardèche mutton is as good as Down mutton), stale and well-baked bread, and a glass of old wine; the vegetables allowed are potatoes and carrots. At four o'clock, the same meal, but with two pounds of grapes. In the evening, soup or tea with white bread, according to the habits of the patient. We recommend exercise between meals, and abstinence from drinking as far as possible. Fontainebleau Chasselas grapes for this cure, which may last three weeks, are far inferior to ours in every respect, because it is to the sugar and gum, the nutritive principles of the grape, that the treatment owes its efficacy. Under its influence, which is in nowise laxative, but tonic and reviving, and at the same time refreshing, the consumptive patient recovers his strength and his flesh, and, *à fortiori*, invalids, whose lungs are less seriously attacked. It is a treatment, says Mr Constantin James, a competent judge in the matter, which succeeds perfectly in allaying general over-excitement, refreshes the blood, discusses pulmonary congestion, and modifies the secretions; it also acts beneficially in diseases of the urinary system. It is an agreeable and useful complement of the mineral treatment pursued at Celles for the cure of these diseases."

So much for the Grape-cure; now for the Whey treatment. This seems to prevail more extensively than the Grape-cure, and we are informed that there are about six hundred establishments where it is practised. The professors of this method are not particular as to the kind of whey employed; that of goats and ewes is, however, preferred. This treatment prevails over the whole of Germany, from Hanover to Austria.

The owners of the Spas seem to be jealous of it, and as the best way of crushing a rival is to make him a friend, the Whey-cure has been attached to the mineral springs, and Ischl, Baden-Baden, and other places have become favourite shrines where health is dispensed in cups of lacteal salines. Dr Carrière says:

"The first dose is taken fasting, and the second after a quarter of an hour's walking exercise in the open air or under shelter, according to the weather. It is almost indispensable that the whey should have been recently prepared; although, as we have already stated, excellent precautions are taken to preserve its temperature. The establishments considered the best renew their stock three times a day, in order to insure its freshness. It is an advantage, not without value, to take the whey on the very spot in which it is prepared, or very near it. If it should come from afar, it is better to drink it at the springs, like a glass of mineral water, than to wait for its distribution. In the early stages of the cure, two glasses are not exceeded; if no obstacle should arise, and no great perturbation of the digestive organs occur, the daily dose may be increased to four or five glasses, equivalent to about 1½ pint of whey. This applies to cow's milk-whey only, according to Dr Mojsisovicz, from whom we borrow all these details. But for goat's or ewe's milk-whey, both less digestible, and applicable, especially the latter, to the cure of pulmonary phthisis, it is essential to proceed with greater moderation."

Such are the very agreeable modes of cure which the fertile imagination of charlatans has invented to amuse the jaded minds and invigorate the bodies of the peripapetic valetudinarians who are hunting for a new sensation through the valleys of Switzerland and the gaming-houses of the Rhine. There is a virtue, no doubt, in the hygienic regimen insisted upon, to which these and all other quackeries owe their chief advantages.

SUMMARY OF THE WEEK.

AMALGAMATION OF THE METROPOLITAN MEDICAL SOCIETIES.

For some years past there has been a wish expressed for an amalgamation of the numerous Medical Societies of the Metropolis. The inconvenience felt in going from one to the other, and the great expense attending Membership of the several Societies, have prompted this desire. Medical men are not over-wealthy; it therefore becomes a serious consideration with a young and aspiring Practitioner, whether he can afford to join the numerous societies which are the resort of the most active and conspicuous Members of the Profession, or whether he must be content to forego the opportunity for intellectual excitation and enjoyment which these reunions afford. Mr Charles Hawkins gave an effective expression to this feeling at the last Annual Meeting of the Medico-Chirurgical Society, and induced that body to appoint a Committee to consider the subject. Other Societies have followed this example—viz., the Epidemiological, the Pathological, and the Obstetrical; and a Joint Committee having been constituted, the following resolution and heads of a scheme were unanimously agreed to:—

"That it is the opinion of this meeting that it

would tend to the advancement of Medical Science, were the Royal Medical and Chirurgical the, Pathological, the Epidemiological, and the Obstetrical Societies united under one head, and these different branches of Medical Science carried out in corresponding sections of one Society."

The scheme proposed was as follows :

"I. That the united Society be divided into the following Sections : 1. Practical Medicine and Surgery. 2. Pathology and Morbid Anatomy. 3. Epidemiology and Hygienics. 4. Obstetrics, and Diseases of Women and Children. 5. Physiology (including Anatomy and Animal Chemistry). 6. Psychological Medicine. 7. Medical Jurisprudence.

"II. That the Treasurers of each Section respectively receive the subscriptions to such Sections, and defray from their own funds the expense of publishing their 'Transactions' and other necessary outlay. That the surplus, if any, be paid into the general fund, and any deficiency be supplied from that fund.

III. That Fellows of the Royal Medical and Chirurgical Society [*i. e.*, of the Societies when combined] be members of all the Sections, and have a right to attend all meetings of such Sections.

"IV. That persons, not Fellows of the Society, be admitted members of any particular Section on payment of an annual sum, and be designated members of such Section, and Associates of the Royal Medical and Chirurgical Society [*i. e.*, the Societies when combined].

"V. That each Section elect annually a president and other officers for the management of the affairs of its own department, and also from time to time elect members who are not Fellows of the Society.

"VI. That in the annual nomination of Fellows recommended by the Council for election as President and Council of the united Society for the ensuing year, two at the least be selected from amongst the members of the Committee of Management of each of the several Sections.

"VII. That members of particular Sections have the right to attend all meetings of such Section, and to be admitted to the use of the reading-room, but not to remove from the library any books, except such as belong to the Section.

"VIII. That it be the business of the Committee of each Section to prepare a report of the proceedings of the past session, to be read at an annual meeting to be held for that purpose."

Whether this plan will materially remove the disadvantages complained of, is a question which the Members of the various Societies must now take into their deliberation. The question of payment has not been specifically touched, and that is the practical evil. The Royal Medical and Chirurgical Society would in all probability be aggrandised by the arrangement, and be launched on a new career of useful service. The London Medical Society has not taken part in the proposal; and this is, perhaps, desirable, as this Society, being the oldest in London, has a character and associations of its own, which it would be a kind of treason to destroy by amalgamating it with any other body.

THE GUERNSEY SURGEONS AND GENERAL SLADE.

We observe that the dispute between the Medical Staff of the Guernsey Militia and the Lieutenant-Governor, on account of the appointment by the latter functionary of a Homœopath on his Staff, has not yet been amicably settled. The Officers of the Militia have recently entertained the Major-General at a banquet, to which the Medical Staff, although still serving, were not invited. We regret that General Slade should have deemed it needful to embitter the controversy by adverting to the honourable and manly course taken by the Medical Officers in these terms : "that no cabal, however *crafty*—no clamour, however loud—and no Press, however powerful, will ever cause me to swerve from the strict line which my conscience points out to me to be the correct one." General Slade no doubt considers this gentlemanly language, but we apprehend that he will find few gentlemen to agree with him. To stigmatise his Officers as a *cabal*, and their conduct as *crafty*, is hardly such language as becomes the dignity of a Lieutenant-Governor or the courtesy of a gentleman.

THE VOLUNTEERS FOR GARIBALDI.

The vices of our military system have been often exposed, and numerous have been the promises of amendment; yet it would seem that very little has been really done to improve our military economy. We apprehend that this is owing very much to the little value generally set by Englishmen on life, as against the accomplishment of a great enterprise. There is an impatience of small things, and a desire to finish a grand undertaking at a blow. We are apathetic when there is nothing to do; but when danger appears, the sleeping lion suddenly rises and springs upon his enemy. If one rush would settle the affair, it would be well enough; but if continued exertion be required, then we are obliged to suffer for that indifference which characterised our days of peace. We are informed that the army of Garibaldi is in desperate want of Medical comforts, Surgical instruments, and appliances of various kinds,—a result that might be expected from the peculiar character of the heroic enterprise in which it is engaged. There is another branch of this subject, however, which appeals more nearly to the sympathies of Englishmen. We are in a position to know that many hundreds of young men, most of them of great respectability, have offered their services to form a Volunteer Corps for Garibaldi, and as soon as vessels can be chartered they are prepared to embark. Now we very much fear that, with the Englishman's usual indifference to the details of supply, these young men will leave our shores without such stores as will be necessary for their health and comfort. The promoters of this movement have received numerous letters from young men who are willing to give their lives, but comparatively few enclosing sufficient sums of money to equip the Corps. We hope, therefore, that our readers who are disposed to be charitable in this cause will remember their own countrymen. Sympathy with Italians is good, but sympathy with Englishmen is better.

SKETCHES OF EMINENT PHYSICIANS AND SURGEONS OF THE LAST CENTURY.

By JOSHUA BURGESS, M.D.

MEMOIR OF JOHN HUNTER, F.R.S.

(Continued from page 147.)

John Hunter's marriage with Miss Home took place in 1771. It would appear that at this time, having been ten years in London as before stated, he had communicated no papers to the Royal Society—in short, had published nothing hitherto in his own name, and what of his had publicly appeared was in his brother's name. In consequence, Sir John Pringle, the President, urged upon him to communicate a paper, which he read in 1772 to the Royal Society, showing that the gastric juice possessed the power of dissolving the coats of the stomach after life was extinct, he having made several experiments elucidating that fact. He incurred great disadvantage by this diffidence in not committing his labours before the public, his opinions being misconceived, and his discoveries and experiments attributed to others and misquoted. This determined him to give lectures upon the Theory, Principles, and Practice of Surgery, during the winter of 1773, to vindicate his fair claims, and to reduce the result of his inquiries to a system by promulgating to the public his opinions upon Surgery. Nevertheless, the fundamental doctrines upon which these lectures were based, owing to John Hunter's anxiety for their perfection were the last amongst his works to be submitted to public judgment. The timidity thus manifested to face this ordeal, and the value he placed upon his reputation, are confirmed by the fact that he revised and corrected these lectures for twenty years before publishing them. At first John Hunter gave lectures free, feeling acutely the deficiency of abilities required for public speaking. In consequence of not forming a part of Medical education, they were badly attended, the class being small. His inability to make himself understood was a great drawback and impediment; his anxiety being so great, and the undertaking so formidable, that it is stated on commencing his labours he was obliged to take thirty drops of laudanum to allay his irritability, and to appease the nervousness and uneasiness he experienced. He notwithstanding courted inquiry, and was pleased to be questioned, especially when his explanations were understood. His mode of lecturing was to make a short abstract of each lecture, and recapitulate it the following evening, to connect the subject in the mind of the students. These gratuitous lectures were continued until 1775, more in self-defence from piracy and misconstruction than from any gratification of vanity. Dr Hunter's logical and didactic eloquence won greatly the admiration of John, being attainments with which he was not endowed, and inspired him with a deference to his brother greater than to other rivals. John Hunter was not understood, because he saw further than had been at that time discovered into the laws of nature and organic life. Notwithstanding his ignorance of grammar, we are indebted to him for many words and terms in familiar use in anatomical language at the present day, and it would seem nature made him a philologist. The singular combination in the character of John Hunter of man of the world and man of science, no doubt gave a peculiar tone to his every-day life. Thus he well appreciated the value of his brother's friendship and patronage, who at that time was in high credit with the first nobility, and even with royalty. But all pretensions to policy, flattery, or even suavity of manners, were alien to him. In the present day we can hardly take a fair measure of him, a rough pioneer penetrating the utter darkness of science, instinct with truth and love of knowledge, entirely destitute of all helps and tools. His unceasing zeal and industry compensated for these disadvantages. The difficulties of the subjects he had to explain were of themselves sufficiently embarrassing, but greatly augmented by the meagre terms and deficiency of scientific language existing at that time in which to convey

his meaning and ideas. The redundancy in our day of Medical terminology affords a singular contrast: we now launch into an ocean of Greek derivatives, many of which will be adopted in no lexicon, and have no abiding home or resting-place.

The characteristic quality of John Hunter's genius was experiment and investigation: toil was no burthen—books and other aids he disregarded, having no faith in the labours and discoveries of others, but delight and confidence in his own. The necessary result of this want of leisure or taste for reading was, that he advanced many what he thought to be discoveries, made many years before by others, with full conviction of their originality. With him labour was its own reward: the great and learned Haller early discovered in the young aspirant the fame which awaited him, and was foremost to appreciate and proclaim to the scientific world the discoveries and merits of John Hunter. That the brothers were strongly attached, there is no doubt: mutual interests, independent of fraternal ties, cemented this natural affection. Had they been less ardent and emulous in the same pursuits, and professed less ambition, the influence of natural affection would have prevailed, mutual happiness would have resulted, and scandal been avoided. Both parties being equally blameable, this unfortunate and almost unnatural strife met with a painful retribution, embittering their latter days, until the grave closed upon their career. William Hunter's success, which was most auspicious throughout, made him impatient of rivalry. Endowed with rare physical and moral qualities, and equal perseverance, being a classical scholar of superior acquirements, he was accustomed to consider his brother in those respects inferior, and also as his pupil. Nevertheless, he was proud to think his disciple so worthy his fostering tutelage and regard. Dr Hunter's facility and elegance of expression—choice of language—freedom from any dialect which did not rather give emphasis and euphony to his musical voice—added to an amenity characteristic of the scholar and gentleman, made his demonstrations, always so accurate, the type for imitation, and conferred a temporary *éclat* and fame John could not approach. Thus flushed with adventitious superiority, Dr Hunter claimed without contradiction every discovery made under his eye.

Eminent as naturalists, these talented brothers succumbed to the frail passions and infirmities of human nature. William appropriated John Hunter's drawings, had engravings made, and in his lectures demonstrated them as his own discoveries. Amongst others, he made engravings of the nerves of smelling, intending to present them to the Royal Society, but which his numerous engagements prevented. The climax of this was the discovery of the circulation of the placenta, of which, with great simplicity and guilelessness, John Hunter informed his brother, and showed him all his experiments and opinions. At first Dr Hunter ridiculed the demonstrations, but afterwards appropriated them in his lectures and work on the 'Gravid Uterus,' without in any way alluding to the discoverer, or mode of discovery.

It is true that, in his preface to this work, Dr Hunter, in alluding to John Hunter's anatomical investigations, speaks of his brother as one "whose accuracy in anatomical researches is so well known, that to omit this opportunity of thanking him would be, in some measure, to disregard the future reputation of the work itself." This was simply a confession of an accepted and self-evident truth, given somewhat coldly and reluctantly, without even those courteous phrases commonly used on such occasions. The opportunity served so well to display a genial and affectionate feeling, that neglecting it, by resorting to such cold, tardy, and unavoidable terms of acknowledgment, roused the quick feelings of John Hunter to a state of uncontrollable turbulence. Now become almost equally distinguished with his brother, he felt how much his anatomical skill had promoted Dr Hunter's prospects. Being engaged in different departments of professional practice, their interests in no way came into collision or rivalry. It occurs often that ties of relationship absolve that practice of courtesies found, nevertheless, under all circumstances, promotive of concord and self-respect. They induce an encroaching tendency, each expecting more than the other is willing to concede. John, as is usually the case, being the younger, was more inclined to forgive—William to resent. John became impatient of this thraldom, which placed the brothers in a false position. In an unfortunate moment, he, by a letter to the Council of the Royal Society, communicated his discovery of the injection of the placenta, twenty-five years before, with all the particulars. This occurred in 1780, only three years before the death of Dr William Hunter; and he never forgave John for this act of rebellion, his resentment being manifested, at the last, by excluding him from notice in his will, and bequeathing the family estate away from him to his nephew, Dr Matthew Baillie. Dr Baillie, so soon as the will was proved, ceded the estate to John Hunter. Dr Adams, with that kindly spirit which strongly characterises his Memoirs of John Hunter, endeavours to extenuate this conduct on the part of William. He insists upon his well-known disregard of money, and his conviction that, although he relinquished the gracious act, nevertheless the paternal estate would surely descend to his brother; his dependence being the greater, from the well-known conscientiousness and sense of justice of Dr Matthew Baillie. Certainly, John Hunter's circumstances at this time rendered him independent of this fraternal regard and posthumous memorial: but, as Dr Hunter most remarkably retained his faculties to the last moment of existence, bright as ever, beaming to the last flicker with a stoical philosophy, the wiping from the tablets of his memory all kindly record of the only near relative he had was a painful incident. The apology advanced confers a meed of grace and justice upon Dr Baillie which William Hunter neglected to perform, and refused to practise himself. After this letter of John Hunter's was received, a letter was read from Dr Hunter at the next meeting of the Royal Society, advancing his claim to the discovery in question. To this letter John Hunter sent a reply; and thus ended this unbecoming and painful dispute. It is, however, pleasing to state that, whatever may have been the feelings of William Hunter towards his brother after this public contention, John's affection survived, and his grief at the entire separation to the end of life was sincere and deeply felt. Dr Adams says—"In the warmth of his heart, he requested that he might at least be invited to the sick-bed of his near relation—his patron and instructor, and the head of his family. This request was complied with, and the relation—the quondam pupil and *protégé*—had the high gratification of administering his professional services in the last moments of life."(a)

(To be continued.)

HOSPITAL REPORTS.

ST GEORGE'S HOSPITAL.

VESICO-VAGINAL FISSURE—DIVISION OF FIBRES OF STERNO-MASTOID MUSCLE FOR CONTRACTED OR WRY NECK—NÆVUS—REMOVAL OF GANGLION ON TENDON OF WRIST.—MR POLLOCK.

(AUGUST 23RD.)—VESICO-VAGINAL FISSURE.

The misery attendant upon this loathsome and pitiable accident, fortunately has stimulated a rivalry of remedial expedients, and resources for its mitigation and cure. Vesico-vaginal fissure is the frequent concomitant of protracted parturition, in which the head of child has improperly been permitted to remain impacted in the pelvis, to the destruction of surrounding soft parts. Incontinence or dribbling away of urine is at first often mistaken for temporary paralysis of the sphincter of bladder, or weakness. At length the real mischief becomes discovered. So much has been lately written and so much discussion taken place upon the various modes of treatment and cure, that the subject has been thoroughly exhausted. Mr Battey and Dr Bozeman, of America, and Mr J. Baker Brown, have invented different mechanical appliances for securing metallic sutures in their use to the fistulous opening of the vagina.—The patient, a woman about twenty-five years of age, had been operated upon by Mr Pollock on ten different occasions, for the purpose of producing contraction of fistulous opening, by paring its sides and edges. This was a very distressing case. The whole of the base of the bladder was gone—had sloughed away. This slow process of inducing contraction, Mr Pollock thought, was the only operation likely to prove successful in this case—to afford mitigation, or ultimate cure. The patient was placed in the recumbent posture, as for lithotomy; being first narcotized. The anterior wall of the vagina was then brought to view, and scissors and tenotomy knife were used in removing a layer of the fleshy cicatrix formed round the margin of the fistula, after the plan of M. Jobert of Paris. The fissure was found much contracted in size since the last operation. By resorting to this plan, the fissure has already become so small and reduced, that the patient is enabled to hold her water with use of catheter. A serious drawback and discomfort frequently occurs from the disposition of the bladder to deposit lithates. These form in bladder, and become deposited in the opening or fistula, thus causing great distress and considerable inconvenience. They are easily dislodged, and removable, when discovered, by dilatation. Mr Pollock related the case of a lady, in private practice, who was painfully inconvenienced by the formation of lithates, which became lodged in the mouth of fissure. Being easily removed by dilatation, she ultimately obtained a perfect cure.

(AUGUST 29TH.)—WRY NECK, FROM CONTRACTION OF FIBRES OF STERNO-MASTOID MUSCLE.

This patient, a young woman of eighteen years of age, was greatly deformed by contraction of right side of neck. Fibres of sterno-mastoid muscle of right side were divided, by subcutaneous section, with tenotomy knife. On a previous occasion she had had fibres of sterno-costal muscles divided.

NÆVUS.

The different modes of destroying these rapidly-enlarging growths are numerous; amongst which, in addition to those by ligatures, may be mentioned injections of perchloride of iron. The patient, a child twelve months old, had a cutaneous nævus on the epigastrium, the size of a large plum—a full inch in diameter. Mr Pollock destroyed it in the following manner:—Passed two strong needles crucially through base of the nævus; round the base, and under these needles, he wound a strong silk ligature; he then freely pierced the nævus all over its circumference with a large needle. As it emptied itself, he wound the ligature again tighter round the base, thus strangling the nævus.

GANGLION ON TENDON OF WRIST

Was removed by subcutaneous section—dividing ganglion, and scooping out its contents. The employment of pressure by compress well applied may prevent return.

GUY'S HOSPITAL.

(AUGUST 28TH.)—AMPUTATION.—MR COOPER FORSTER. AMPUTATION.—MR COCK. LITHOTOMY—ADENOCELE.—MR BRYANT.

AMPUTATION.

This woman, a patient about forty years of age, had been afflicted with malignant ulcer of long continuance, situated on anterior aspect below lower third of tibia. Altogether it had a very anomalous, yet no specific character could be given it. Treatment afforded no amelioration, nor did it rapidly extend. Latterly it had become excessively painful, and prevented locomotion. Mr Forster thought it best to amputate, so as to afford sufficient stump for adaptation of artificial leg. This operation he performed by double lateral flaps above lower third of leg.

AMPUTATION.—MR COCK.

A man, forty-three years of age, received injury of ankle-joint and lower part of leg; dislocation of tibia inwardly—fracture of fibula internally, attended with great injury to joint. Exfoliation at extremity of tibia had taken place. Mr Cock considered amputation best to be done in this case. The dislocation being irreducible, and extremities of bones being found in a state of disease, prevented any use of the limb. He performed the double-flap operation in the usual way, at lower third of leg. The two bones were found so much injured as to be nearly approximated, and scarcely to allow introduction of the scalpel between. The arteries were also found in a condition of disease, and excessively brittle. In so young a subject, this must be attributed to injury the having set up conditions of degeneration.

LITHOTOMY.

We are advocates of free-trade equally for professions as for commerce. Special Hospitals we

consider to be excellent *media* for what may be termed *eccentric* charity. In this country, special or eccentric charity will always obtain. The *millionaire* of the upper middle class may purchase a philanthropic distinction by eccentric benevolence, for which his mode of making money never afforded an early opportunity. Why not give this opportunity to the founding of a Special Hospital? The question of Special Hospitals having recently occupied attention, suggests these remarks. A Stone Hospital is considered to be particularly indicated as a requirement. Hearing, as we do, all opinions, the facts before us may serve better than laboured argument to elucidate this question. It is stated that lithotomy so rarely occurs at General Hospitals, that pupils may not see above one or two cases during some months' attendance. We have now to relate four cases of lithotomy performed at this hospital within a few days, and three of them following each other on one day. We, moreover, have recorded more than a dozen cases of lithotomy within the last four or five weeks at the Hospitals of King's College, Guy's, and St Thomas's.

A boy, about thirteen years of age, was cut for lithotomy by Mr Bryant. The lateral operation was promptly performed upon this patient, and the stone easily and quickly removed. The stone was large, rough, of mulberry nucleus and phosphatic shell. The semirotary force required was calculated to remove it with celerity, decision, and neatness. It is gratifying to us, who have been "an eye-witness" of the golden era of operative surgery—who have seen Astley Cooper use the knife in his meridian—to testify that the power has not passed away, and that the rising generation will wear the mantle, if not as *gracefully*, as *well*. This patient had not been conscious of existence of stone in the bladder until the last six weeks. The whole operation was concluded, save dressings, in little more than a minute, with as little apparently to be done as in the extraction of a tooth; the incisions being made with not more than three sweeps of knife—no pause, no haggling—and stone extracted.

ADENOCELE

Is a term of extensive signification, although applied to diseased tumours having a limited locality—namely, the female breasts and the mammary glands. It expresses the type of *benign*, in opposition to *malignant* tumours. Adenocele recommends itself, in consequence, as a more agreeable subject of inquiry. It is found amongst young, and generally unmarried women, from sixteen to forty years of age, the preponderance of cases being amongst single women. Abernethy describes it as "Pancreatic Sarcoma;" Sir Charles Bell, "Cysto-sarcoma;" Velpeau, (*a*) as "Tumor Adenoide;" Sir Astley Cooper, "Chronic Mammary Tumour." Sir Benjamin Brodie calls it "Cerocystic Tumour;" Mr Paget, "Mammary Glandular Tumour." It has received other various designations from both French and English pathologists, and has been divided into three series. Birkett describes these growths as having three marked divisions "established by nature," having numerous varieties. The first he describes to consist of new growths, having small fibrous bands connecting epithelial cells, of compact dense form—fibrous, lobed on surface, and internally enveloped in their own fibrous capsule. Thus, the illustrations and varieties of adenocele are extremely numerous, and described under different names. All are benign, non-malignant growths, belonging to one class, each manifesting a different development in its external form. The tumour is sensible to touch, and painful upon movement—also attended with lancinating pains. The pain causes excitement and flushed cheeks, and its continuance is diagnostic of adenocele. The tumour moves freely, and slips from finger and thumb upon pressure under integument. In short, all seems free about the breast. The nipple does not become retracted; but if the tumour increases in size, the skin stretches, and breast becomes pendulous. The areola becomes enlarged in surface, and follicles are distinct; but it retains a healthful complexion. The nipple, although small and flattened, is not retracted. The prognosis in these tumours is always favourable. Amputation is not necessary, or indicated, unless the enlargement becomes progressive. Nevertheless, as the operation is simple, it is best performed at early growth. It is a mere resemblance of malignant cancer, having no other characteristic symptoms. The secreting portion of the gland, the excretory ducts, and *cæci*, are well formed, as also the cæcal terminations of ducts. Mr Birkett, in one case, attempted to save the nipple. The tumour returned, of the size of an orange, and became of a crimson red colour; it assumed a malignant aspect, became prominent and fungoid, occupying the situation of the nipple. It was not ulcerated, not offensive, and no sloughing occurred. The woman was young, unmarried, and in good health.

The patient Mr Bryant operated upon was a healthful woman, about twenty years of age. The breast was well developed, and little or no deformity. The tumour was situated above and extending from the nipple, on the superior aspect of the left breast; it was freely moveable—tissues, cutaneous and subcutaneous, being natural, clear, and free from nodules. Mr Bryant fixed the tumour with finger and thumb of left hand; he then carried a longitudinal incision over the tumour, extending a little beyond either extremity, for about four inches down to the tumour; it was easily dislocated by pressure, and removed from its capsule; one or two vessels were secured, and the lips of the wound brought together by ligatures and strapping. The tumour consisted of dense epithelial cells, connected by small fibrous tissue, enveloped in membranous capsule.—Adenocele is of *recurrent* tendency. An instance of clear diagnosis and prognosis, given in a case of adenocele by Sir Astley Cooper, is recorded by Mr Birkett. In 1857, a woman, eighty-four years of age, consulted him, with a tumour hanging below her navel larger than her head. Fifty-three years before, she had consulted Sir Astley Cooper about it, who told her it would never do her any harm. In short, these tumours are perfectly innocuous.

OUR NOTE BOOK.

LIGATURE OF THE CAROTID FOR SUSPECTED ANEURISM OF THE OPHTHALMIC ARTERY.

We recollect seeing Mr Bowman tie the carotid artery (about three years ago) for a supposed aneurism of the ophthalmic artery, in an elderly woman, at King's College Hospital. The patient had applied at the Moorfields Ophthalmic Hospital for a noise in her head. A pulsation either within the orbit or the head had been heard for five months by herself, and also by her husband. Its origin, Mr Bowman observed, was somewhat obscure—whether from a blow or otherwise, he could not say positively; but she had received a blow on the lower edge of the orbit, which might have produced a fracture and lacerated the vessel. The lower edge of the orbit was very uneven; possibly a fracture may have ruptured the coats of the ophthalmic or the internal carotid itself. He remarked that it was not difficult to determine the real nature of the disease. The eye was prominent and injected, and so were the other structures of the orbit. A pulsation was felt over the eye, then over the whole head, but the left side particularly; and a strong, loud bruit was heard. The only thing to be done was to tie the vessel; and this was performed on February 27th, after the patient had been a week in hospital to prepare for it. She was by no means a favourable subject; she had lived a very hard life, subject to considerable excitement with her husband, and was frequently drunk. She had no disease of the heart or other vessels. The upper portion of the common carotid was ligatured sufficiently below the bifurcation to permit the formation of a clot, and was there easily got at. On the 6th of March the patient was going on well; the noises had disappeared, as also the congestion of the eyeball, &c. Afterwards she died; and at the autopsy no aneurism was found to explain the symptoms present during life.

We have been thus particular in mentioning these facts to show how difficult it is always to make out correctly an aneurism within the orbit or head. Very recently another case of supposed aneurism of the ophthalmic artery was submitted to the same treatment, and so far it has been followed by good results in every way. Subjoined are the particulars, as kindly furnished us by Mr William Wickham, house-surgeon to King's College Hospital:—

Susan L—, aged forty-one, admitted April 13th, 1860, with supposed aneurism of the right ophthalmic artery. She states that she has generally enjoyed good health. On Dec. 27th, 1859, whilst washing some clothes, she was attacked by sudden pain in the right side of the head, followed soon afterwards by a "blowing" noise in the same part, both of which have continued ever since. The right eye gradually became protruded and swollen, with increased vascularity. In March, 1860, she was confined. On admission, the right eye is found to project forwards about a quarter of an inch, and she has a convergent squint of about two lines. There is complete paralysis of the right external rectus muscle. When told to look towards the right hand, there is seen to be a second convergent squint of the left eye. The conjunctiva of the right eye is very red and œdematous, the sulcus beneath the orbit being completely filled up. The right eye is presbyopic. She is able to distinguish the figures of a watch held at a distance of fourteen inches, but cannot read, being unable to recognise letters of a word at that distance. On pressing the fingers beneath the margin of the orbit, a faint and obscure pulsation can be felt. The veins of the upper lid are varicose. The supra-orbital artery beats naturally. On applying the stethoscope over the front of the eyeball, a loud, blowing murmur, synchronous with the radial pulsation at the wrist, is heard, as also over the whole of the right side of the head, though more subdued in character. It is also heard on the opposite side of the head, but in a much fainter degree; also at the right angle of the lower jaw over the course of the common carotid artery down to the root of the neck. The intensity of the murmur is diminished on compressing the common carotid, but the bruit is not altogether stopped. Heart-sounds are quite natural, though occasionally she suffers from violent palpitation. The treatment adopted at the commencement consisted in the administration of tonics and pressure of the carotids by means of the fingers. This pressure was kept up for about ten days, twice a day, for five minutes at a time, with the effect of completely stopping both the throbbing and the pain for the time being. As this, however, gave no permanent relief, it was discontinued, and, for the temporary relief of the patient, irrigation and cold to the parts have been since applied.

From the date of her admission till June 15th she continued in much the same condition; but in the evening the prominence of the eye became much more apparent, with an increase of vascularity and pain to such an extent that Mr Bowman determined at once to ligature the common carotid, and performed the operation on June 16th in the ordinary way.

The patient has proceeded favourably since the operation, with a relief to most of the symptoms complained of, and is at the present time (July 31st) in a fair way of recovery. The ligature came away on the seventeenth day, without hæmorrhage. The eye is still prominent, and the paralysis of the sixth nerve is permanent. A faint bruit is occasionally heard.—'Lancet.'

GOOD EFFECTS OF BLEEDING IN ACUTE LEPRA.

Although bloodletting is recommended by Gibert and other writers on skin diseases at the commencement of cases of lepra, besides the regiminal and medicinal treatment, it is not often that we see it put into practice. A case, however, came under our observation a few days back at the Charing-cross Hospital, in which venesection to the extent of ten or twelve ounces was followed by the best results. The patient is a stout, plethoric woman, twenty-four years of age, who was admitted under Dr Willshire's care, with her body covered with lichenoid papules. The skin was as rough as shagreen or nutmeg-graters, the intervals between the papules being of an intensely red colour. This eruption appeared in the course of a single night. The small venesection was followed by the most sensible relief, and she was then ordered half-drachm doses of bicarbonate of potass in the infusion of dulcamara. Under this treatment the eruption disappeared in a week's time, the skin subsequently desquamating, as is witnessed after scarlet fever. Her diet consisted chiefly of milk and eggs.

In the same ward we observed another example of lepra, in a female of thirty years of age, which was not unlike the syphilitic form: here the

patches were interspersed with roseola; the eruption arose from drinking cold water while the body was in a heated condition. The patient was rapidly improving under the use of bicarbonate of potass and small doses of the iodide of potassium.—'Lancet.'

THE PITUITARY BODY.

Dr Michel has published a monograph on the Pathology of Pituitary Body. It is extracted from the 'Charleston Medical Journal.' He has laboriously collected much information relative to the very obscure subject of the pathology and physiology of this (to us, at present) curious body. These are the conclusions to which his investigations have led him:—"1st. That the pituitary body, however largely developed in some animals, is not a primary division of the brain, or a true encephalic ganglion, since its complete destruction is never accompanied by loss of intellection, motion, or sensation, beyond what may be satisfactorily accounted for by the necessary pressure which the morbid growth exerts upon more essential parts of the encephalon. 2nd. That from several of the morbid processes enumerated in this memoir, we have strong proof of the identity of the nature of this hypophysis with certain so-called vascular glands, such as the thyroid, thymus, spleen, and supra-renal capsules. 3rd. That while the diagnosis of its morbid conditions is rendered somewhat obscure from the absence of any ascertained function of the part, yet their almost constant connection with the simultaneous production of amaurosis in both eyes, with absence of symptoms of cross paralysis, will indicate the seat of the disease, when compared to morbid states of either hemisphere. And fourthly, that the long continuance of disease in this situation may propagate inflammatory action to neighbouring parts, followed by apathy, somnolency, syncope, cophosis, and other symptoms obscuring the diagnosis."—'Medical Times.'

POSTURE IN PRESENTATIONS OF THE FUNIS.

Dr Brandeis, of Louisville, relates three cases in proof of the advantage of treating presentation of the funis by placing the mother on her knees and elbows, and supporting the body with pillows in such a manner that the pelvis is kept a good deal higher than the chest. Reposition is then performed, and the patient kept in the position until strong pains come on. Even when the circulation of the funis is feeble, it is soon restored after compression has been thus removed. For the success of the manœuvre it is requisite that the os uteri be dilated or dilatable, and the liquor amnii must be partly retained. If it has all escaped and the uterus is firmly contracted over the child's body, all efforts at reduction will be in vain. Collecting the statistics from various writers, Dr Brandeis finds that 695 instances of prolapse have occurred in 177,184 labours, or 1 in 264; while in 743 instances of prolapse 408 still births occurred.—'Boston Journal,' and 'Medical Times and Gazette.'

SUCCESSFUL CASE OF OVARIOTOMY.

Dr Crosby relates in considerable detail the particulars of a successful case of ovariotomy. The patient was thirty-six years of age, and had two children. The disease had existed for more than five years. It was a large uniocular tumour, the solid parts weighing rather more than 3 lbs., and the glairy contents less than 25 lbs. During the five years, 475 lbs. of fluid had been drawn off by tapping. Although long tormented by obstinate vomiting, she recovered so well that in five weeks she was enabled to direct her household affairs.—'Boston Journal,' and 'Medical Times and Gazette.'

OVARIAN CYST SUCCESSFULLY INJECTED WITH IODINE AFTER UNSUCCESSFUL ATTEMPT AT REMOVAL.

Dr Wythes relates the case of a woman, aged twenty-two, upon whom he undertook the operation of ovariotomy; but the sac being found universally and firmly adherent to the abdominal parietes and viscera, he was obliged to give up the attempt. This was on June 2nd, and on the 15th, after evacuating a pint and a half of exceedingly offensive pus, he threw in through a catheter two ounces of tincture of iodine; and on the 17th, four ounces more. On the next day the contained fluids were found so coagulated that the mass was broken up with difficulty by the catheter. After several days, the sac having been well washed with tepid water, three ounces more were injected, and the injections were repeated every few days until the middle of July—using in all about a pint and a half of the tincture, by which time the sac had so contracted as to admit but about an inch of the catheter. This was in 1858, and the patient has continued well since, only wearing an elastic abdominal bandage.—'North American Med.-Chir. Rev.,' and 'Medical Times and Gazette.'

ON RETENTION OF URINE IN THE FŒTUS AS A CAUSE OF OBSTRUCTED LABOUR.

The substance of this paper constituted a communication to the Academy of Medicine some years since, but has never been before published in full. Judging from the silence of writers on Midwifery upon this subject, M. Dépaul observes, this cause of difficult labour can be but little known. But although cases of retention of the urine in the fœtus carried to this extent may be rare, others are far more common, in which, owing to the secretion having continued during a less lengthened period, or having been less abundant, the tumour resulting from its accumulation has been much less considerable, or may have passed unperceived at the period of birth. At present, the Author confines his attention to the obstetrical relations of these cases, proposing on a future occasion to demonstrate the fact now generally denied—viz. that the functions of the kidneys become established at an early period of fœtal life, the urine passing, by reason of the contractions of the bladder, through the canal of the urethra into the liquid amnii, of which it is indeed one of the principal sources. The following is an abstract of the particulars of the case which occurred in M. Dépaul's own practice, and related by him at great length:—

A lady, twenty-eight years of age, in her third pregnancy, found at the fifth month that she had attained the size usual at the end of gestation, this exaggerated size having begun to manifest itself after three months and a half. The movements of the child, too, perceived first at about the fourth month and a half, were very feeble, and kept getting more and more so. Soon after the sixth month labour-pains appeared, and in the course of twenty-six hours dilatation had become complete. Notwithstanding, however, that the pains of late had become very active, no progress seemed to be made, and no liquor amnii was discharged. The midwife, wishing to expedite matters, used various violent tractions, the consequences of which were that the cervical spine became broken, and one arm and the head were detached from the body. A Practitioner who was called in detached the other arm and opened the thorax; but, notwithstanding the evacuation of the lungs and heart, the trunk could not be delivered. After eight hours' endeavour of this kind, the Author's aid was sought, the pains having now become feeble, but the patient's condition being in no wise alarming. He was at once struck by the enormous size of her abdomen, the fundus of the uterus extending six fingers' breadth above the umbilicus, while the organ had assumed the size of an uterus at full time when distended with a large quantity of liquor amnii. On examination, the abdomen of the infant was found to be enormously distended, and this was at first attributed to ascites, although such large effusions into the peritoneum during intra-uterine life are very unusual. An opening in the abdomen was forced by means of the finger, and about a quart of a sanguinolent serosity was discharged. Notwithstanding this, it still continued immensely distended, and a fluctuating tumour was still to be felt. Perforating this with the nail, a quantity of transparent, citron-coloured fluid gushed out, which was estimated at about five pints. After this discharge the delivery was easily completed, and the patient did as well as after a natural labour. On examining the fœtal abdomen, and restoring it by means of insufflation to the large size it had prior to the punctures, it was found to measure twenty-one *centimètres* in the transverse, nineteen in the vertical, and fourteen in the antero-posterior diameters—and this independently of the increase which had taken place from effusion of serosity into the peritoneum. The abdominal walls themselves had also undergone a considerable thickening from serous infiltration. The distended bladder, the muscular walls of which were much hypertrophied, occupied almost all the cavity of the abdomen, the organ being in its largest circumference thirty-five *centimètres*. Three canals opened at its surface, the two ureters and the large intestine. This last terminated on the anterior side (its normal calibre having been diminished after coming in contact with the bladder to that of a small quill), its aperture being scarcely detectable. Externally there was no indication of the orifice of the anus. The immediate cause of the urinary tumour was the obliteration of a portion of the canal of the urethra.

M. Dépaul quotes in detail cases more or less resembling this one related by Portal, in his 'Pratique des Accouchements;' by Mr Fearn, in vol. ii. of the 'Lancet' for 1834-35; by M. Delbovier, in the 'Archives de Médecine Belge;' by M. Gaudon, in the 'Bulletins de la Société Anatomique' for 1846; and by M. Duparcque, in the 'Annales d'Obstétrique' for 1842; and from the whole he draws the following conclusions:—1. The urinary secretion is established at an early period of fœtal life. 2. When, from vicious conformation or other obstacle, the urine cannot at this period of life be expelled into the cavity of the amnios, it accumulates in the bladder, and this organ may then attain dimensions which renders spontaneous delivery impossible even when the pelvis is perfectly well formed and the period of pregnancy is not complete. 3. So great have been the difficulties thus produced, that in several cases the head and limbs have become detached without the obstacle being overcome. 4. Whenever an examination of the parts has been made with exactitude, it has been plainly demonstrated that, together with this development of the size of the bladder, there has co-existed a hypertrophy of its walls, and especially of its muscular coat, showing that the organ does not play merely the part of a passive reservoir, but that it frequently endeavours, during pregnancy, to expel the fluid it has received. 5. The cases on record would seem to show, that while it may be well nigh impossible to recognise the nature of such a case during pregnancy, a strong probability, if not certainty, may be arrived at respecting it during the progress of labour. 6. The rarity of simple ascites carried to this extreme degree will at once lead to the presumption of a distension of the bladder; and retention of urine may be declared to be present when malformation of the genital organs can be made out by exploration. 7. Under any circumstance, the practice to be pursued is the same. When tractions, carried as far as prudence will permit, have failed, evacuation of the fluid must be resorted to. 8. As the vices of conformation of the urinary organs in question do not necessarily compromise the viability of the infant, it is absolutely necessary to practise the operation of puncture with all due precaution. The insertion of the funis will serve as a safe guide to the most favourable spot. 9. In proceeding in this way, it may not be impossible, by means of another operation, performed after delivery, to re-establish the natural passage of the urine, and thus save the life of the child.—'Gazette Hebdomadaire,' Nos. 20, 21, 23; and 'Medical Times and Gazette.'

FORMULÆ FOR CREOSOTE.

M. Lebert employs a lotion consisting of from one to four parts of creosote to 1000 of water, as an application in burns, and in putrid or cancerous ulcers; and in the treatment of wounds and ulcers M. Guibert applies charpie, soaked in a mixture composed of four ounces of glycerine and twelve drops of creosote.—'Bull. de Thérap.,' July, p. 26.

ON THE EMPLOYMENT OF CHLORIDE OF ZINC IN DISEASES OF THE SKIN.

Dr Veiel, of Constatt, says: Since Hanke in 1841 directed attention to the properties of chloride of zinc, I used it in my hospital, as a caustic, in cases where it was desirable to destroy morbid growths in the connective tissue, or to remove abnormal deposits, as frequently occurs in various forms of lupus. For a long time I employed it only in the treatment of lupus and of allied diseases, as lepra vulgaris, elephantiasis, small circumscribed scirrhosities, &c.; it was not until lately that I made use of it for modifying the vitality of pus-secreting surfaces in ulcers on the feet of long standing, in chronic eczema, in sycosis, or for the destruction of funguses, as in pityriasis versicolor, favus, &c.

In the Institution the chloride is employed in three forms: the spirituous solution, the watery solution, and in the solid state as pencils or cylinders. The first consists of equal parts of rectified spirit and chloride of zinc; the second, of ten parts of chloride, ten of hydrochloric acid, and 500 of water: the third is prepared by fusing the chloride and pouring it into moulds, as in the preparation of caustic potash. I designate these three forms: spiritus, liquor, and lapis zinci chlorati.

The lapis I select when the object is to penetrate to the greatest possible depth for the destruction of hypertrophic deposits, as frequently occurs in inveterate cases of hypertrophic and tuberculous lupus, in which the agent is employed precisely in the mode recommended by Langenbeck in the use of caustic potash.

I made use of the lapis in my hospital with the best possible result in thirteen exquisite cases of hypertrophic lupus, six times on the upper lip, four times on the cheek, twice on the ear, and once on the ala nasi.

The following is the mode of proceeding:—Where scabs or thick scales are present, which have already destroyed the epidermis, cataplasm are employed for their removal; but where the epidermis is still intact, it is separated by blistering plaster or water of caustic ammonia. The lapis, placed in a quill, and pointed, is now worked into the hypertrophic or tuberculous tissue, to a distance of about two or three lines, until, when the surface is large, the pencil has penetrated all the excrescences in various directions. Immediately after this operation, in which the pencil sometimes penetrates with remarkable ease to a considerable depth, but at others enters with difficulty, and only superficially, there flows from the honeycomb perforated surface at one time dark, at another light-coloured blood (which is removed by means of a sponge), and soon after a clearer serum, which, in the course of a few hours, hardens to a smooth and firmly-adherent scab. This, partly in consequence of the swelling of the surrounding tissues, partly in consequence of the loss of substance, already presents a rather depressed appearance. On the third or fourth day thin pus forms at the margin of the scab, and is removed by acupuncture, which generally greatly diminishes the tension. On from the sixth to the eighth day, the scab loosens at the edges, whereupon it is completely removed by means of poultices, which are to be continued for several days. The application of the lapis to the tubercles and ridge-like striæ is now repeated, especially in the more prominent parts, until the hypertrophic tissues are destroyed, proceeding as at the first. It is, in general, seldom necessary to apply the lapis more than three times; it was only in one case of an hypertrophic cheek, which was destroyed from the eyelid to the edge of the jaw, and in the latter place was, in its entire breadth, almost as thick as the finger, that I was obliged to use it much more frequently. When the great wound is at length free from all puffy elevations, and has been brought down to a level with the surrounding healthy parts, it is poulticed for several days, lightly smeared every three or four days with spiritus zinc. chlor.; and, subsequently, when the edges have begun to contract, with the liquor, until a perfect cure is obtained, which seldom requires more than three or four months.

In lupus exfoliativus and exulcerans, without hypertrophic infiltrations, the use of the spirit continued to the complete destruction of the fully, or half-developed, or already softened tubercles is sufficient, after which the liquor is likewise employed until the cure is effected. In this case the morbid surface, deprived of its epidermis by a blister, is lightly touched with a pencil dipped in the spirit. This application is attended with violent pain and profuse secretion of albuminous serum, which partly flows off and partly combines with the zinc to form an eschar of albuminate of zinc. The eschar is at first firmly adherent, but after three or four days it separates, with profuse secretion of watery pus. The interval between the first and second cauterisation is shorter with the spirit than with the lapis, about three or four days; in this instance, too, the separation of the eschar by the suppuration must determine the time for further cauterisation. As to the liquor, which is intended only to hasten the process of healing, it will be sufficient to use it every five or six days.

The lupus superficialis seu erythematosus of Cazenave and Hebra—I should like to call it the red, shagreen-like lupus of the face—requires for its treatment the spirit diluted with the liquor, as in it much more superficial layers of the integuments are affected, and the subcutaneous areolar tissue is rarely implicated.

Hence the indication for the employment of the three forms of the chloride of zinc is evident: the lapis is to be used wherever hypertrophic tissues are to be removed; the spirit, where the object is to destroy morbid subcutaneous tissues, and degenerated and more superficial layers of integument; the liquor, where it is desirable to promote the cure by means of an astringent and stimulating application, and to secure the formation of a firm cicatrix.

Besides lupus, chloride of zinc is consequently useful in a great number of cutaneous diseases, which I shall now briefly mention.

In obstinate eczema occurring at the boundary between mucous membrane and cuticle, as on the eyelids, the lips, the labia pudendi, the anus, smearing with the spirit is highly serviceable. In the case of the eyelids, the hairs or ciliæ must first be removed. Here one cauterization was usually sufficient; while on the mouth and labia pudendi it must be repeated. When the delicate scab was separated, the eczema was generally cured. In eczema solare and impetiginoides daily smearing with the liquor is often the only mode, when all other means have failed, of effecting a cure. In eczema of the tongue, too, gaping fissures of the nipples and scrotum, of the palms of the hands and points of the fingers (tylosis), the quick of the nails, &c., the mixture of the spirit with the liquor, in the proportion of one part to ten, has often alone effected a cure, particularly in the quick of the nail, which often forms an unconquerable source of vesicular eruptions. This mixture has also done good service in warty erosions of the tonsils and back of the pharynx, where daily pencillings are necessary.

In psoriasis some remains after treatment with with tar, which often continue as large as peas on the elbows, back, or upper part of the thigh, are particularly easily destroyed with the spirit, the scabs being first scraped off with a knife. There is also a palmar psoriasis attended with painful corn-like thickenings, which yield to no other remedy but the lapis, after they have been raised out of their bed by means of a blister.

In sycosis and favus the liquor is very useful, after the hairs of the beard, or head, have been removed. In these affections it acts partly by resolving the swelling and infiltration of the follicle, and partly, as in favus, by arresting the formation of fungi. The same is true of some forms of acne; I also employ with good effect, after the resolution of the tubercles, the combination of sulphur with alcohol, recommended by Hebra.

A great number of warty, circumscribed scirrhosities of the nose, cheek, and lips have been very successfully destroyed with the spirit.

In chronic ulcers of the feet, especially when they have callous edges and a false membrane at the bottom, which has become an independent secreting surface, the destruction of this membrane by the spirit is of great use, particularly when the callous edges are at the same time removed by the knife.

In cysts, too, glandular swellings which are constantly suppurating, and fistulous passages, only one or two applications of the spirit are required to destroy the secreting membrane.

In syphilitic secondary ulcers (syphilides ulcerosa) the mildest treatment is certainly the best, and caustics are not applicable; but in condylomata, in soft warts, molluscæ, the cauterization of the roots, after the protuberances have been removed with the knife, is of great value. The employment of the liquor was also successful in sebarrhœa, burns, and chilblains.

It now remains for me to point out the advantages presented by chloride of zinc in the treatment of cutaneous diseases, as contrasted with some other caustics in use.

Its principal advantages consist in—

1. That it enters into combination with all elements with which it comes in contact, especially with protein and albuminous matters, while the compounds so formed in their turn produce a penetrating, cauterizing irritation, whereby the parts in the neighbourhood of the eschar contract, diminishing the wound and approximating the edges of the sound part.

2. That this irritation produces a more rapid formation of pus and separation of the eschar, causing the healing process to proceed much more quickly, the surfaces of the wound to form more rapidly, and to exhibit better granulations.

3. That the cicatrization is better, in consequence of the peculiar contraction and uniform destruction of the parts.

4. That the pain, though considerable, lasts only a proportionably short time, and can, consequently, be very much moderated by the use of chloroform.

In these qualities the chloride of zinc excels,

a. The acids, which produce rather a coagulation of the albuminous matters, and form a leathery eschar, which does not penetrate very deeply, and separates only slowly and with difficulty, while the shrivelling of the capillary vessels has a weakening effect on the healing process.

b. Caustic potash, which produces a saponification of the soft parts, incapable of being accurately limited, readily corroding the neighbouring tissues by the secretions to which it gives rise, and likewise creating eschars difficult of separation, which leave neither healthy suppuration nor vigorous granulations.

c. Lapis infernalis, which acts much more superficially, and produces more tedious separation of the destroyed parts, thus giving rise to more persistent pain and less perfect cicatrices.

d. The preparations of iodine (Richter's iodide of glycerin and the preparations of iodide of mercury) likewise penetrate more slowly, create greater reaction of the healthy surrounding parts, are, consequently, also more painful, and, on account of the greater or less amount of iodine they contain, are more uncertain.

With chloride of gold, chloride of bromine, Landolfi's paste, Petrequin's caustic solution of gold in aqua regia, &c., I have made no comparative experiments; nor have I made more use of the pulvis cosmi, or the other preparations of arsenic, which I have avoided on account of their danger and uncertainty, so long as I found the chloride of zinc to satisfactorily replace the other caustics.

I close this short paper with an expression of my wish that chloride of zinc may occupy the same important place in the treatment of cutaneous diseases, that I and others procured twenty-five years ago for green or Dutch soap, as an indispensable agent in the cure of these affections.—'Zeitschrift der k. k. Gesellschaft der Aerzte zu Wien,' 20th Feb., 1860, page 113, and 'Dublin Quarterly Journal.'

EXAMINATION OF SPUTUM FROM A CASE OF CANCER OF THE PHARYNX AND ADJACENT PARTS.

For the interesting specimens of cancer figured in Plate III, I am indebted to the kindness of my friend, Mr Newham, of Bury St Edmonds. They were present in sputum expectorated by a woman, aged forty-four. Mr Newham sends me the following history of the case:—

"Case.—The patient was a small, spare woman, with small features, and very pale. She had never been married, and had for some years been a cook in London. Her health for some years past had been indifferent, but, being of an active disposition, she had never been obliged to discontinue her employment.

"About thirteen weeks ago she was seized with great pain, apparently situated about the centre of the base of the skull, extending to both temples and over the head generally. She was never free from it, and often it increased in severity. There was a dry cough. In a few weeks the throat became sore, and the effort of swallowing produced pain, but nothing could be seen upon carefully examining the mouth and throat. The pain in the head gradually increased, and deglutition became still more troublesome. The pain in the head was so much increased by sleep, that she feared its approach, and refused to take anodynes. At length sputum made its appearance. The cough always appeared convulsive in character, and was accompanied with nausea and a desire to clear the throat of discharge, and did not seem to result from pulmonary obstruction. The sputum was not in the least offensive until a day or two before death. Gradually, in addition to the pain of swallowing, that is, of the *muscular*

effort necessary to the act, there arose a difficulty of getting the food beyond a certain spot opposite to the thyroid, but no swelling could be detected by external examination in this region. At length the cervical glands began to enlarge; the pain and difficulty of swallowing from obstruction of the œsophagus increased. The sputum became more abundant, and her strength failed. She died from exhaustion consequent upon the small quantity of nutriment she was able to take. For the last three weeks of her life she refused all medical aid. As she became weaker the pain diminished, and almost subsided a few days before death."

Mr Newham thus describes the post-mortem appearances :— "The cervical glands involved were situated just outside the carotid sheath. A portion sent for examination was removed from the under surface of the sphenoid and occipital bones; in fact, from the roof of the pharynx. The bones were carious, but whether so originally or from the ravages of the disintegrating deposit did not appear. It felt pulpy, fibrous, and somewhat gritty. The thyroid was considerably enlarged, and a portion of it, which was as hard as bone, was impacted between the larynx and œsophagus, and pressing so tightly on the latter for the last fortnight as to render deglutition almost impossible."

Microscopical Examination of the Sputum.—A portion of the sputum was placed upon a slide and covered with thin glass, and examined without the addition of water or any chemical reagent. The appearances observed are carefully delineated in Plate III. The drawings were made upon the wood-block, and were accurately copied from the specimens in the microscope. I am indebted to Mr Wragg for the beautiful and very perfect manner in which the engraving has been carried out. It is only justice to the engraver to say that so perfect a representation of microscopical appearances on wood has very seldom been obtained.

The specimen is a very instructive one, and shows the manner in which the cancerous mass grows. On a cursory examination, it would appear that the drawings confirm the statements of many observers with regard to the so-called endogenous multiplication of cancer-cells, and excellent examples of the so-called parent cells seem to be scattered abundantly all over the field, but a careful study of the subject proves that the different bodies alluded to are not cells at all. Only a few of the general forms which these bodies assumed are represented, but there were other intermediate shapes too numerous for representation. The observations upon the character of these bodies will equally apply to a number of cancerous growths; but as the appearances in this case were so unusually distinct and well defined, and as it was quite impossible they could have been produced by artificial means, I have selected them for careful study.

Now it will be observed that the bodies in question are not all composed of the same material. Some refract light differently to others, as indicated by the different varieties of shading, and there is an absence of that granular appearance which is observed in the greater number of specimens figured. The cellular appearance of many of the bodies in question is fallacious, and many that would be termed mother-cells are only masses of granular matrix with nuclei irregularly scattered through them. In some instances these have broken in such a way as to leave cavities into which the nuclei evidently fitted. At *p*, fig. 1, such a mass is seen, and at the lower portion is a cell-like piece nearly detached, with others which are quite separated. It is difficult to explain all the appearances represented in the figure, and for the present I shall content myself with illustrating the principal forms exactly as they appeared in the microscope. They were not treated with any reagent. Water was not even added, so that the appearances represented are not produced by any artificial processes whatever. A portion of the mass removed after death is represented in fig. 2, and in fig. 3 the microscopical characters of one of the cervical glands are indicated.—[L. S. B.]—'Archives of Medicine.'

TREATMENT OF EXCESSIVE PERSPIRATION OF THE FEET.

It is well known that excessive perspiration of the feet may be a very troublesome complaint. It not unfrequently produces excoriations between the toes, giving rise to an exudation of a disgustingly fetid odour; and it sometimes occasions ulcerations, which render locomotion very painful, or altogether impossible, forcing the persons affected to interrupt their business occupations. M. Gaffard, of Aurillac, recommends the following means, which he says he has employed in such cases with complete effect. The treatment consists in pouring between the toes a few drops of a liquid, composed of one gramme (fifteen grains) of red oxide of lead, and twenty-nine grammes (about an ounce) of the solution of subacetate of lead (of the French Pharmacopœia): the sesquioxide of lead is pounded in a mortar of porcelain till it is finely divided; the subacetate is added gradually; and the whole is put in a bottle, which is shaken each time it is used. This application made every eight days is sufficient, in most cases, according to M. Gaffard, to cure the affection, and prevent its return. The liquid, without completely stopping the perspiration, moderates its amount, and regularizes the action of the morbid surfaces. The perspiration becomes inodorous, the skin regains its original thickness at the excoriated parts without losing its pliancy, and the parts return to the natural condition of cleanliness and health.

BISMUTH AND GLYCERINE IN THE TREATMENT OF BURNS AND SCALDS.

Professor Richardson, of the Charity Hospital, New Orleans, states that this combination constitutes the best application he has yet met with. The bismuth is to be rubbed up in a mortar with a sufficiency of glycerine to form a thick paste, which should be applied by means of a camel's-hair pencil, or a soft linen mop. Previously to employing it, the parts should, if possible, be thoroughly dried, to which end it is necessary to prick with a needle any blisters that may exist, and carefully wipe the surface by gently pressing it with a piece of dry lint. A thick coating having been applied, the parts should be protected from friction by a sheet of clean carded cotton. In very slight burns, in which there is erythematous redness without discharge, dry bismuth may be dusted on, the secretions of the skin forming with it a pasty, protective coating. —'North American Med.-Chir. Review,' July, p. 656.

ENDERMIC USE OF ANIMAL FAT IN TYPHOID FEVER.

In the 'Southern Medical and Surgical Journal' for June, Dr Baker, of Alabama, has an article upon the above subject: Dr Baker thus reports his experience: "I have for the past five years employed it (animal oil) in all cases (of typhoid fever) where there existed a harsh and dry skin, with the unfailing effect of rendering it soft and pliant, just as it would an old piece of indurated leather. In scarlet fever its application is specially indicated, both during the height of the fever, and in the subsequent stage of desquamation. I have found nothing so beneficial in softening the skin and soothing the irritation during the eruption; and I have also ascertained that its continued application during the period of convalescence, combined with the occasional use of the warm bath, tends almost certainly to prevent the subsequent and so much dreaded dropsical effusion.

"In that dry, hot, and dropsical condition of the skin so often observed during the first two weeks of typhoid fever, when the hand may be held in contact for any length of time with the patient's skin, without producing the slightest moisture, or changing in the least its dry and harsh state, inunction produces the most happy effect; the hot, dry, shrivelled, and harsh skin becoming cool, moist, smooth, and pliant."

We should be happy to make several extracts from the lengthy paper of Dr Baker, but must content ourselves with one or two more. He says, "The reason why I have recommended animal fat in typhoid fever originates in no idea of its exclusive adaptedness to that disease. Its good effects, when thus applied, are equally manifest in many other wasting and long-continued diseases: and here, in passing, I will say, that it is especially advantageous in the *tabes mesenterica*, occurring in the second year of infancy. In such cases, the endermic application of cod-liver oil affords more promise of success than all other medication combined. Indeed, what medical practitioner in the southern country has not heard the old nurses on plantations boasting of the cures they have worked by 'washing' some little, weak-necked, scrawny-limbed, big-bellied infant in 'pot-liquor?'"

Dr Baker concludes his paper thus: "Such is my faith! May I be pardoned for saying, only with that degree of confidence with which the truth should be proclaimed, that I prove my faith by my works, in safely conducting by these means (animal fat externally, and turpentine and brandy internally) many patients through attacks of typhoid fever, and bringing them out in the end emaciated to no great degree, but, on the contrary, with such an integrity of tissue as insures a much more speedy convalescence than takes place in ordinary recoveries.—'American Medical Monthly.'

CAMPHOR AS AN ANTIDOTE TO STRYCHNINE POISONING.

In the 'Pacific Medical and Surgical Journal' for June, Dr M. T. Dodge reports a case of poisoning by strychnine, entirely relieved by the administration of camphor. According to the report, *five grains* of strychnine had been taken *three hours previously*. Ten grains of camphor were given in emulsion, and repeated every half-hour or hour for seven hours, when the spasms entirely ceased, and the patient rapidly recovered. It would certainly be a fortunate discovery should camphor be found to be a reliable antidote to the poisonous action of strychnine. The case reported lacks at least two essential points to make it available as proof upon this point. It is thought by many that much of the strychnine in use is nearly inert, and, if taken as claimed, there is no proof that the article was genuine. More than this, there is no proof but the patient's statement that the five grains of strychnine had been taken at all. There is certainly one suspicious fact in the case, that must in some measure detract from our confidence in the antidotal power of camphor. *Three hours* had elapsed from the taking of the poison before remedial aid was had; and yet the patient was sitting up, and presented no very alarming symptoms. Professor Wood says that, in cases of poisoning from strychnine, the alarming symptoms usually follow the administration in from ten minutes to half an hour. One of two things is evident: the five grains were not all taken, or the poison was not of standard strength; either would affect the result, so far as relates to the antidotal powers of camphor.—'American Medical Monthly.'

LONDON HOSPITALS.

The medical public are so bent at the present moment upon investigating the whole question of hospital management, consequent upon the general *versus* special hospital discussion, that we think it advisable to draw our readers' attention to a matter which bears most intimately upon clinical instruction in our great hospitals. Let us, for instance, take St Bartholomew's Hospital. This great medical institution contains 650 beds, of which 410 are surgical cases, and 230 are medical; whilst the medical officers are four for each department. Hence it follows that each surgeon has to attend about 102, and each physician about fifty-seven patients. When we remember that bedside instruction is the great practical instruction to which medical pupils have to look in order to prepare themselves for the duties of one of the most arduous and anxious of professions, we may very properly demand that this kind of instruction be the very best that can be afforded to them. But what are we to say to a gentleman hurrying through wards containing 102 beds, and "doing" the list within the hour? We have seen something of this scampering process;' and we are bound to say that students, under such conditions, cannot be said to be "walking" the hospital, but running the hospital. It is little more than half a minute to each patient. Can the surgeon call this clinical instruction? Can he do either his patients or his pupils justice? We have mentioned St Bartholomew's Hospital first, for the simple reason that it stands at the head of the metropolitan list; but the same vice of under-officering our general hospitals is observable in nearly all of them. St George's, with 350 beds, has a staff of eight physicians and surgeons. The London Hospital, with 310 surgical beds, has only three

surgeons; and, with 135 medical beds, only three physicians. Guy's, with 550 beds, has but nine medical officers. Able as these gentlemen may be, it is totally impossible that, in the limited time they have at their disposal in the middle part of the day, they can minister to the wants of the afflicted in a satisfactory manner. Twenty-eight per cent. of the patients of the General Hospital at Hamburg pay both for their maintenance and medical care. The State Hospital at Christiania, in Norway, is maintained entirely by the payments of its patients. In the Chronic Hospital of the same city, all inmates who are non-residents pay for their medical care. In Berlin, again, the rule is to find medical institutions paid for by patients' fees. Among these we may mention the Infirmary for Female Patients, partly self-supporting; Von Graefe's Ophthalmic Infirmary, *wholly maintained by patients' fees;* and the Orthopædic Institutions of Eurenburg and Kruse, both also maintained by patients' fees. Even in the Parisian hospitals, private rooms are set apart for paying patients. If payment for medical aid were the rule in our great hospitals, there would be no need of reducing the fees of a staff far more numerous than is at present possessed; the afflicted poor would be gainers morally as well as physically; and the pressure on the public, in the shape of appeals from insolvent hospitals, would be materially lightened.—'British Medical Journal.'

LEGAL INTELLIGENCE.

IMPORTANT TO MEDICAL MEN AND THEIR ASSISTANTS.—BLOOMSBURY COUNTY COURT. SCOTT *v.* EVANS.—This was an action brought by the plaintiff, a surgeon residing at Camden town, against the defendant, his late assistant, to recover the reduced sum of 6*l.*, incurred through the latter's breach of faith in leaving him suddenly without notice or any person to fulfil his duties, whereby he had been put to great expense and inconvenience. Mr W. B. Davies, solicitor, was for the plaintiff, and Mr Ablett for defendant.

From plaintiff's statement, it appeared that defendant entered his service on the 21st of June, 1859, at a salary of 40*l.* a year, with board and residence, and a month's notice of leaving to be given on either side, his duties being to dispense medicines and keep the books. On a Sunday evening in March last the defendant returned home inebriated, saying that he was going out again to spend the night with a friend he had not seen for some time, when witness, expostulating with him, objected to such a proceeding, telling him that if he did, he should the next day give him notice. Defendant replied he must go, and departed, and he (plaintiff) kept his word by giving him notice. Three weeks then elapsed, and he was about closing an engagement with another assistant, when defendant requested that his misconduct, which should never occur again, might be forgiven, and that he might remain; to which, on these conditions, plaintiff consented. He stopped till the 21st of June, when, addressing plaintiff, he said, "Now, unless you give me 10*l.* a year more salary, I shall go directly." Repudiating with astonishment such a demand being made, he, of course, refused it, and defendant went away. He was thus left alone in his business, and it was some time before he was suited with an assistant, paying till then 11*l.* 10*s.* for the services of temporary ones, although he had sued for only part of that amount, money not being his object, but thinking that defendant ought to suffer something for his folly, and himself and others of his class receive a caution for the future.

In answer to Mr Davies, plaintiff emphatically denied ever promising to raise defendant's salary 10*l.*; but at Christmas last gave him 5*l.* as a present for his exertions in completing the books, which were greatly behind, saying that he might on a future occasion repeat the compliment.

Defendant, in reply, said, understanding that at the expiration of twelve months his salary was to be raised to 50*l.*, and plaintiff when asked refusing to do so, he considered he was entitled to leave at once.

His Honour (Mr Lefroy) observed that if even the case had been as stated by the defendant, he was not justified in acting as he did; for surely it was not likely that a medical man would subject himself to be left at once without an assistant. He believed that at the engagement of defendant a month's notice was agreed upon, and on the part of the latter he thought the case a very bad one, and that the plaintiff had been lenient in suing for so small an amount, instead of the whole sum he had been out of pocket.

Judgment for plaintiff, with the whole of the costs.

Births, Marriages, and Deaths.

BIRTHS.

CLAREMONT.—September 3, at Thorney place, Oakley square, the wife of C. C. Claremont, Esq., M.R.C.S., of a son.

COLEBROOKE.—August 31, at Southborough, Tunbridge Wells, the wife of H. Colebrooke, M.D., of a daughter.

D'OLIER.—August 31, at York place, Bow road, the wife of J. A. D'Olier, M.B., of a daughter.

JONES.—September 2, at St Thomas's street, Southwark, the wife of Sydney Jones, M.B., F.R.C.S., of a daughter.

KINGSFORD.—September 2, at Upper Clapton, the wife of C. D. Kingsford, M.D., of a daughter.

SCORESBY-JACKSON.—August 30, at Queen street, Edinburgh, the wife of Scoresby-Jackson, M.D., of a daughter.

MARRIAGES.

HOLMAN—STREET.—August 30, at Reigate, Constantine Holman, M.D., to Marion, younger daughter of William Street, Esq., Retreat, Reigate.

WILTON—ROBERTSON.—August 28, at Indego, Tarland, Charles Edward Wilson, Esq., H.M.'s Inspector of Schools, to Jeanne Farquharson Robertson, second daughter of Andrew Robertson, M.D., Commissioner to H.R.H. the Prince Consort.

DEATHS.

BUSIGNY.—August 29, suddenly, at Ombersley, Droitwich, Worcestershire, Charles Edward Busigny, M.R.C.S. Eng., L.S.A. Lond.

DOOLAN.—August 24, at Bath House, Totterdown, Bristol, John Livesey Doolan, M.R.C.S. Eng., formerly Surgeon of the Royal Navy, aged 83.

GOSSET.—August 29, at 3 Atlingworth street, Brighton, Daniel Gosset, M.D. St Andrew's, M.R.C.S. Eng., L.S.A. Lond., formerly of Leicester, and of Reading, Berks, aged 86.

HEY.—September 1, at Ellesborough Rectory, Bucks, Richard Hey, of York, Fell. (Hon.) and M.R.C.S. Eng., L.S.A. Lond., Consulting Surgeon to the York County Hospital, &c.

KELAART.—August 31, suddenly, of disease of the heart, on board the Steamship 'Ripon,' on the evening before her arrival at Liverpool, Edward Fredk. Kelaart, M.D. Edin., M.R.C.S. Eng., Staff Surgeon in the Army, aged 41.

MACCROSSAN.—August 29, at Dublin, Thomas MacCrossan, M.D., M.R.C.S. Ireland.

MEERES.—September 3, at 19 King street, Finsbury square, Thomas Meeres, M.R.C.S. Eng., L.S.A. Lond., aged 63.

MORRIS.—June 30, at Lucknow, Charles Fredk. Morris, Assistant-Surgeon 23rd Foot (Royal Welsh Fusileers), aged 30.

SCOTT.—August 30, at 139 Falkner street, Liverpool, Roger Wakefield Scott, M.D. Univ. Edin., aged 59. He was in succession Physician to the Liverpool Dispensary and Northern Hospital, and Lecturer on Medicine at the Royal Institution Medical School.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of Medicine, and received certificates to practise, on Thursday, August 30th, 1860:—Alfred Frederick Stafford Clarke, Manchester; Thomas Cotton, Spalding, Lincolnshire; John Vivian Faull, Bristol; William Gayton, London; John Thomas Jenkins; Oliver Calley Maurice, Marlborough, Wilts. The following gentlemen also on the same day passed their first examination:—William Bowes, London Hospital; Frederick Marsdin, King's College; Thomas Henry Passmore, Guy's Hospital.

THE OPHTHALMOLOGICAL CONGRESS will be held this month at Heidelberg. Many of the leading ophthalmic physicians and surgeons of Europe are expected to be present.

ON THE COMBINATION OF MEDICINES, AND ON A NEW IODO-FERRIC PREPARATION OF COD-LIVER OIL.—"For more than fifteen years," says M. Devergie, "I have endeavoured to apply to medicine the principle that, in morbid states of the constitution, it is less the use of *any one* therapeutic agent that should be had recourse to, than the combined use of many from which, when tried separately, an equal measure of success is derived. Thus, for instance, the experiments of Guersant and others on chloride of barium, decoction of walnut-leaves, iodine, and also on those agents which have succeeded them—viz., cod-liver oil and iron—have brought out statistics which award to each of these medicines a number of cures, a number of cases in which relief has been experienced, and a number in which no effect has been visible; from which I have been led to the idea that by the combination of these medicines for the treatment of scrofulous affections, we should probably arrive at a cure in a much shorter time; and experience has confirmed me in this idea." In the same way, in syphilitic cases, M. Devergie has advantageously employed a combination of mercury, iodide of potassium, iron, and arsenic. According to him, then, there exist anti-scrofulous, anti-syphilitic, anti-vermic agents, whose efficacy varies with the temperament and constitution of the patient, and with the degree and form of the disease, there being, at the same time, no exclusive treatment for any one period of the disease. Thus, if iodide of potassium is, *par excellence*, the treatment for secondary and tertiary symptoms, it is because in these cases we have exhausted the power of mercury. Hence, then, it is desirable to employ the composite form of all medicines; only that it is necessary to combine them, so that each shall preserve its power of action uninjured and unneutralized by the others. However, by this system we do not consult the tastes of the patient, who is obliged to take at the same time a great many substances more or less disagreeable. For example, M. Devergie for many years has prescribed for scrofula at the same time cod-liver oil, syrup of iodide of iron, gentian wine, and walnut decoction; and this is the preparation from which he has experienced the greatest success. M. Vezu has already endeavoured to associate pure iron with cod-liver oil in an iron oil. M. Devergie, in his turn, has tried a combination of the iodide of iron and cod-liver oil. The following is the formula:—R Pure iron filings, gr. vi.; iodine, gr. xxv.; water, q. s. Combine by trituration in a mortar the iodine and iron, adding a few drops of water; then incorporate the iodide so formed with cod-liver oil, ℥xviii. It is of no importance whether the oil is clear, yellow, or brown.—'Bulletin de Thérapeutique.'

HEALTH AND MORALITY IN SCOTLAND.—As far as the present year has yet gone, it has been one of unprecedented mortality in Scotland. The number of deaths registered during the second quarter of this year has been 2,490 more than the corresponding quarter of 1859, and many more than during the corresponding quarter of any year since the Registration Act came into operation. The mortality has been at the rate of 1 in every 42 persons, the corresponding mean of previous years having been only 1 in every 50 persons. The deaths in town have been 1 in every 37 persons, thus greatly exceeding those in the country districts, where there has been 1 in every 53. Thus the first six months in this year seem strikingly to illustrate the truth of the statement, that the state of the weather in Scotland influences the mortality even more than the occurrence of epidemics. Since January, 1855, when the Registration Act first came into operation, there has been no such continued severe weather as during the past six months; and the Registrar-General of Scotland observes that, though smart epidemics have prevailed in former years, and no general one of a fatal character during the half-year just completed, yet the deaths in that period have exceeded the average by 5,575. Meanwhile, the actual increase of the population during the quarter has amounted to 6,820 persons. It is to be lamented that so many of these new subjects of the realm have been brought into the world illegitimately. In this respect Scotland still retains a melancholy pre-eminence. 2,494 illegitimate births occurred in the quarter, or 1 illegitimate in every 11·3 births. Of course the proportions vary greatly, in the north-eastern division rising as high as 13·7 per cent., at Aberdeen to 14·2, and at Kinross to 14·1. In the southern and north-eastern divisions, where the population is chiefly engaged in agricultural pursuits, love among the stubble the Registrar-General considers to be as

fatal to morality as love among the roses is reported to be. Surely an intelligent supervision might discover and destroy the roots of this evil.

A QUACK DOCTOR IN TROUBLE.—At the Dudley County Court on the 25th ultimo, an action was brought by a labourer, named Sampson Skinner, and his wife, to recover the sum of 10*l.* from a person who styles himself "Dr Miller." It was stated that, on the 21st of June last, the plaintiff and his wife went to the herbal establishment of "Dr Miller," in Dudley, and asked for a pennyworth of Epsom salts. Mrs Miller, in the absence of her husband, gave plaintiff a packet. Upon reaching home, Mrs Skinner dissolved the substance in some water, and proceeded to take it. Remarking a strange taste about it, she asked her husband to taste it also, which he did, and was immediately seized with vomiting. As he had only taken a small quantity, the effect was not very severe. His wife, however, was taken seriously ill, a surgeon had to be sent for, and for some time her life was in danger. The substance given for Epsom salts was found to be sulphate of zinc, a deadly poison when taken in large doses. His Honour at once gave a verdict for the full amount claimed, commenting severely at the same time upon the conduct of Miller in leaving such poisons within the reach of persons ignorant of their deadly effects.

POISONOUS MILLINERY.—Erdmann and Ziureck have frightened the ladies of Leipsic and Berlin with the discovery that some green tarlatans were coloured with arseniate of copper. The colour was merely fixed on with starch paste, so that the least friction sufficed to remove it. Erdmann also speaks of a colouring matter known as cochineal red, which contains a good deal of arsenic in the form of arseniate of alumina. At Berlin, Herr Ziureck was officially appointed to investigate the matter, and he found a good many specimens of green tarlatans which were coloured with the arsenical preparation applied superficially, as described by Erdmann. Certainly the air of a ball-room in which many of such dresses were rubbed together would become rather strongly charged with poisonous matter.—'Chem. News.'

SMOTHERING INFANTS.— There appears something for sad reflection in the recent account of four inquests, and also of six, held by Mr. P. F. Curry, the Coroner for Liverpool, and reported in a local paper in the following curt manner:—The first, on the body of Thomas Cæsar Hope, infant son of Robert Hope, joiner, Warren street. The deceased was found dead in bed on Sunday morning.—Verdict accordingly. The other cases, with the exception of one found drowned, are alike—all found dead in bed on Sunday morning.

MEDICAL CHARITIES.—By the will of the Right Hon. Louisa, Dowager Baroness St John (Lady Vaughan), the following hospitals receive legacies of 100*l.* each:—The Northampton Infirmary, the Bedford Infirmary, the East Sussex and St Leonards Infirmary, and the Middlesex Hospital.—The Rev. John Griffith, M. A., Rector of Merthyr Tydvil, preached an admirable sermon, in Bangor Cathedral, on Sunday last, in aid of the funds of the Carnarvonshire and Anglesey Infirmary; and notwithstanding the cathedral was crowded to excess by wealthy visitors from Liverpool, Manchester, &c., only 23*l.* were collected.

APPOINTMENTS FOR THE WEEK.

Wednesday, September 12.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, September 13.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.
London Home.—2 p.m.

Friday, September 14.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, September 15.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, September 17.

Operations at the Royal Free Hospital, 2 p.m.
Metropolitan Free Hospital, 2 p.m.

Tuesday, September 18.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

We find it necessary to repeat that Dr KIDD has ceased to report for the MEDICAL CIRCULAR, and that we shall be obliged by all Communications being addressed to the Editor, at the Office, 20 King William street, Strand.

H. H.—1st. Yes.—2nd. The Act only authorises a charge to be made according to qualification.

A SUBSCRIBER.—1st. Several pathologists have expressed the opinion that any cause preventing a due arterialisation of the blood is also a preventive of tuberculosis; Rokitansky instances even cyanosis. You are right as to the *rationale* of it.—2nd. No.

M.R.C.S. ENG.—We have received your note, and will bear the suggestion in mind.

Mr BIRD.—Certainly.

Mr PORTER Communication received.

M.D.—It is not compulsory to register, but it is desirable that you should do so. We understand that many young practitioners do not register until they obtain an appointment; this is unfortunate, as it prevents the 'Register' from being complete and authentic.

INQUIRER.—The experiments alluded to were made by Hewson.

INCOGNITUS.—We cannot comply with your request.

Mr WILLIAM S.—There is no entrance fee. We should advise you to join the Society.

A MEMBER OF THE ASSOCIATION. — You should write to Dr Wynter, who will probably give your opinions the required publicity in the Association's Journal.

Dr J. H. B.—1st. No.—2nd. No.

Dr H. is thanked for the paper.

AN OLD SUBSCRIBER.—As you have not enumerated the hydriodate of potass among the remedies employed, we advise you to try it, as it is generally esteemed the best for that form of ulceration. Nitric acid is also a valuable remedy.

Mr B. SMITH.—It shall be attended to.

Dr RORIE.—Received.

Dr ROBERTSON.—Received.

L. S.—No communication on the subject adverted to could be noticed.

C. D. (Newcastle-on-Tyne). — You cannot be admitted at the London College at present.

Mr DE LISLE.—Received with thanks.

Dr MCMILLAN.—Communication received, and shall be inserted.

T. M. (a Subscriber).—Mr Haynes Walton's is the best practical work on Diseases of the Eye.

CHIRURGUS (Manchester).—1st. Undoubtedly.—2nd. Make no difficulty about it.

OS UNGUIS.—Not without an operation.

Letters received (with enclosures) from W. J. Dawes, C. Clark, W. W. Roberts, C. Lomax, Dr R. Wood, J. C. Murray, J. Jones, Dr Nicolson, W. Walford, R. Lewis, W. P. Murphy, R. Gilbertson, Dr D'Esterre.

BRIET'S CELEBRATED PATENT GAZOGENE,

OR

AERATED WATERS APPARATUS,

For the immediate production of Soda Water, Ginger Beer, Sparkling Wine, Lemonade, &c. Sole Agents for Great Britain: MATHIEU and FRIQUET, 5A Little James street, Bedford row, London, W.C.

This Agency was first established by one of the Partners (Mr F. Mathieu), who kept it from 1851 to 1854, and is now a branch of the Patentee's Paris Establishment. It is the only house in the United Kingdom supplied by the Patentees, and there is no other having the right to use the name of Agents for them.

MATHIEU and FRIQUET are manufacturing the GENUINE LEMON SYRUP, made from the actual fruit. When used with the Aërated Water from the Gazogene, it gives a pure and wholesome sparkling Lemonade of the most exquisite and refined flavour.

POWDERS for GENERATING GAS in the Apparatus.

Special and able Workmen from the Paris Manufactory are kept on the premises, for the prompt and sound repairing of the Gazogenes, at low charges. No other repairer appointed by the Manufacturers.

Wholesale and for Exportation only.

*** This Apparatus is the best extant, and the only one warranted to stand any climate.

Price Lists sent on application on receipt of Business Card.

Guy's Hospital.—The

MEDICAL SESSION commences in OCTOBER. The INTRODUCTORY ADDRESS will be given by Dr WILKS, on Monday, the 1st of October, at Two o'clock.

MEDICAL OFFICERS.

Physicians.—G. H. Barlow, M.D.; Owen Rees, M.D., F.R.S.; W. W. Gull, M.D.

Assistant-Physicians.—S. O. Habershon, M.D.; S. Wilks, M.D.; F. W. Pavy, M.D.

Surgeons. — Edward Cock, Esq.; John Hilton, Esq., F.R.S.; John Birkett, Esq.

Assistant-Surgeons. — Alfred Poland, Esq.; Cooper Forster, Esq.; T. Bryant, Esq.

Obstetric Physician.—Henry Oldham, M.D.

Assistant Obstetric Physician.—Braxton Hicks, M.D.

Surgeon-Dentists.—T. Bell, Esq., F.R.S.; J. Salter, Esq.

Surgeon of the Eye Infirmary.—John F. France, Esq.

LECTURERS.—WINTER SESSION.

Medicine.—Owen Rees, M.D., F.R.S.; W. W. Gull, M.D.

Surgery.—John Hilton, Esq., F.R.S.; John Birkett, Esq.

Anatomy.—Alfred Poland, Esq.; Cooper Forster, Esq.

Physiology.—F. W. Pavy, M.D.

Chemistry.—Alfred Taylor, M.D., F.R.S.

Experimental Philosophy.—Arthur Durham, Esq.

Demonstrations on Anatomy.—Arthur Durham, Esq., and Walter Moxon, Esq.

Demonstrations on Morbid Anatomy.—S. Wilks, M.D.

Gentlemen desirous of becoming Students must give satisfactory testimony as to their education and conduct. They are required to pay £40 for the first year, £40 for the second, and £10 for every succeeding year of attendance; or £100 in one payment entitles a Student to a Perpetual Ticket.

Dressers, Clinical Clerks, Ward Clerks, Obstetric Residents, and Dressers in the Eye Wards, are selected according to merit from those Students who have attended a second year. A Resident House-Surgeon is appointed every six months from those Students who have obtained the College Diploma.

Six Scholarships, varying in value from £25 to £40 each, will be awarded at the close of each Summer Session, for general proficiency.

Two Gold Medals will be given by the Treasurer—One for Medicine and One for Surgery.

A Voluntary Examination will take place at entrance, in Elementary Classics, and Mathematics. The three first Candidates will receive respectively £25, £20, and £15.

Mr STOCKER, Apothecary to Guy's Hospital, will enter Students, and give any further information required.

GUY'S HOSPITAL, July 1860.

St Bartholomew's Hospital

and MEDICAL COLLEGE.—The WINTER SESSION will commence on OCTOBER 1st, with an INTRODUCTORY ADDRESS by Mr SAVORY, at Eight o'clock p.m.

LECTURES.

Medicine—Dr Baly and Dr Kirkes.
Surgery—Mr Lawrence.
Deseriptive Anatomy—Mr Skey and Mr Holden.
Physiology and General Anatomy—Mr Savory.
Chemistry—Dr Frankland.
Superintendence of Dissections—Mr Callender and Mr Smith.
Demonstrations of Morbid Anatomy—Dr Harris.

SUMMER SESSION, 1861, commencing MAY 1st.

Materia Medica—Dr F. Farre.
Botany*—
Forensic Medicine—Dr Black.
Midwifery, &c.—Dr West.
Comparative Anatomy*—
Practical Chemistry—Dr Frankland and Mr Attfield.

* These Lectureships on Botany and Comparative Anatomy have been recently vacated, but the names of the Lecturers will be shortly announced.

HOSPITAL PRACTICE.—The Hospital contains 650 beds, and relief is afforded to more than 90,000 Patients annually. The In-Patients are visited daily by the Physicians and Surgeons, and Clinical Lectures are delivered—On the Medical Cases by Dr Burrows, Dr Farre, and Dr Black; on the Surgical Cases, by Mr Lawrence, Mr Stanley, Mr Lloyd, and Mr Skey. The Out-Patients are attended daily by the Assistant-Physicians and Assistant-Surgeons.

COLLEGIATE ESTABLISHMENT. — Students can reside within the Hospital walls, subject to the rules of the Collegiate system, established under the Direction of the Treasurer and a Committee of Governors of the Hospital. Some of the Teachers and other Gentlemen connected with the Hospital also receive Students to reside with them.

SCHOLARSHIPS, PRIZES, ETC.—At the end of the Winter Session, Examination will be held for Two Scholarships of the value of £45, for the year. The Examination for Prizes and Certificates of Merit will take place at the end of the Winter and Summer Sessions.

Further information may be obtained from Mr Paget, Dr Kirkes, Mr Holden, or any of the Medical or Surgical Officers or Lecturers; or at the Anatomical Museum or Library.

ON THORACENTESIS:
ITS INDICATIONS AND COUNTER-INDICATIONS IN PLEURISY.

DELIVERED AT THE HÔTEL-DIEU,

By M. ARAN.

On the Seat of Pleurisy, especially Pleurisy of the Right Side, and its Relations with Pulmonary Tuberculisation.

You have twice seen me, during the last few weeks, perform thoracentesis on two subjects suffering from pleurisy with effusion. Of these two patients, the one affected with pleurisy of the left side has already left the hospital, perfectly cured. Of the second patient I shall now speak somewhat in detail. This patient was operated on for pleurisy of the right side; and I now take advantage of the circumstance in order to point out to you the indications and the counter-indications of this operation, and shall at the same time speak of the operation itself, the precautions to be taken while operating, and the accidents that may occur during or after the operation.

The patient on whom this operation was performed is a man of thirty-nine years, a ship's painter, who was received into the Hôtel-Dieu on the 9th of June last. Though of a feeble constitution, of a lymphatic temperament, and extremely emaciated, he had never before been ill. He has no habitual cough, is not liable to colds in winter, and has never spit blood; yet his father, he says, died at the age of forty-three years, from a long-continued affection of the chest, which we believe must have been tubercular phthisis. This information we shall presently take advantage of in establishing a point of the diagnosis. His mother, who is now seventy years of age, has, on the contrary, always enjoyed a state of perfectly good health. The hygienic conditions in which our patient has always lived have been very favourable; nor has he committed any excess, or suffered from want, or ever experienced, notwithstanding his occupation, the slightest symptom of lead-colic.

On the 27th of May last, when working in the open air, he was seized with cold; the following night he had slight shivering, followed by fever; and the next day, May 28, when about to return to his work, he complained of a painful degree of lassitude, though at this time there was no impediment to respiration, and he had no cough. On the morning of the 29th he first felt a stitch under the right false ribs, which became aggravated by every respiratory effort, and by cough, which was dry. Beyond these, there was neither diarrhœa nor vomiting, but only headache, which was severe; and there was well-marked difficulty of respiration. The pain seemed to leave the part of the side which it first occupied, for a part a little below the nipple, where it continued for eight days and then spontaneously disappeared. But, notwithstanding this, the patient's sufferings and the difficulty of respiration only became greater; his voice, too, became more and more obscure and abrupt; and then he decided on coming to the hospital. Up to this time there had been no serious treatment.

The following was his state when seen, June 12:—He is seated on his bed in a half-reclining position: the face is considerably emaciated and pale; the eyes greatly sunk; the skin slightly hot; the pulse from 92 to 96 a minute, and moderately full; respiration, 26; slight cough, but without expectoration; nor is there pain on pressing on the part of the side where the stitch was felt. On uncovering the patient, we were struck with the singular appearance of the chest. The two sub-clavicular depressions are greatly shrunk; while, on the other hand, at the lower part of the right side there is a prominent dilatation, characterised by an outward projection of the ribs, with distension and enlargement of the intercostal spaces. The chest, on the same side, during inspiration, dilates *en masse*, without contraction of the intercostal muscles; but the contractions of the diaphragm are equal on both sides. When the hand is applied to the lower part of the chest, where it is enlarged, and the patient made to speak, there is no perceptible vibration. Resonance is completely lost in the whole anterior part of the chest, excepting over the first intercostal space and at a very circumscribed point near the sternum, and the dulness is the more marked the lower you percuss. The liver surpasses the edge of the ribs, at the median line, six centimeters, and two and a half at a line drawn parallel from the papilla. The mediastinum seems pushed as far as the left synchondro-costal line, and the heart deviates slightly to the left. Throughout the whole of this side percussion produces a degree of sound that contrasts sufficiently with the dulness of the right. During auscultation of the anterior and upper part of the right side of the chest, inspiration is perceived to be feeble, and is followed by a prolonged expiration. In the same situation, too, the voice and cough have a marked resonance; but in all the parts underneath where percussion gives a dull sound, respiration is not perceptible. Considerable autophony and bronchophony are perceived, as well as distinct œgophony. At the upper part of the left side respiration is loud and very strong, and the expiration prolonged. There is, too, very sensible resonance of the voice. In every other part the respiration seems normal. The heart-sounds are feeble; and at the base of the heart there is a soft bellows-sound, which extends as far as the large vessels of the neck.

Percussion and auscultation of the back of the chest furnish signs not the least important. The right side, at its lower part, is sonorous over a triangular space, of which the lower border, passing from the middle of the dorsal column, cuts obliquely the spine of the scapula, near its middle. The whole of the chest below this line is perfectly dull, and presents to the finger a degree of resistance that increases the lower the finger descends. On the left side, excepting a slight degree of dulness near the upper part, the sound is normal throughout. On the right side the respiration is heard distinctly enough in that part which continues sonorous, but below that it is completely lost. Corresponding with the line where the dulness begins, there is distinct bronchophony; and with a point formed by the inferior angle of the scapula there is perfect œgophony. On the left, the respiration is strong and loud, especially at the summit. On the part of the digestive organs there is nothing deserving notice.

On the following day, June 13th, the state of the patient was just the same, with exception of modification of some of the physical signs. Thus, under the right clavicle, near the sternum, there exists, but to a very limited extent, a tympanitic sonorousness, plainly and distinctly cavernous; and the bellows-respiration in the same point is nearly amphoric.

If we now consider the principal symptoms presented by our patient, and take into account the initial shivering, the difficult respiration, the pain in the side aggravated by deep inspiration and efforts to cough, the complete absence of expectoration, the disappearance of the respiratory manner in the two lower thirds of the right lung, œgophony so distinct at the angle of the scapula, the loss of thoracic vibrations; the extensive dulness on the same side of the chest, which has a form and resistance that might surely be called *special*;—if we take all these signs into account, every one must recognise the existence of no inconsiderable pleuritic effusion.

But does our diagnosis carry us only thus far; and is it not possible also to ascertain the nature of the effused fluid, and to say whether in this instance the pleurisy is simple or complicated? Without fear of going too far, I believe I can affirm that the liquid is serofibrinous, as it is in all recent inflammatory exudations of serous membranes. In support of this assertion, I would adduce the recent date of the affection, the circumstance that gave rise to it—that is, exposure to cold—and the initial shivering followed by febrile reaction. I would farther say that this effusion is not simple hydrothorax; for our patient shows no affection of the heart or kidneys, or any of the symptoms of a confirmed diathesis, which are the most frequent causes of serous effusions in the pleura. For the same reasons I would reject the notion of a purulent fluid, as there is the absence of slight, irregular rigors, recurring usually in the evening, and the absence, too, of any adynamic or ataxic symptom, and especially the recent origin of the symptoms.

Let us next examine whether our patient's pleurisy is simple or complicated. You are not ignorant of the fact that the pleura may be effected with different kinds of inflammation; some of which are *primary*, and others *communicative* and *symptomatic*. The former, when occasioned by cold, make their appearance in persons otherwise in perfect health, and of strong, robust constitutions. They all manifest intense febrile reaction, have all a decidedly inflammatory character, have all a regular and rapid course, and soon attain a favourable termination. You will see presently whether such is the case in the example under consideration.

As to secondary and symptomatic pleurisies, no less common than the preceding, their occurrence is observed under extremely various circumstances. You may often see them arise during the convalescence of patients from long diseases—typhus fever, for example. I cannot, as regards this fact, too strongly insist on the care with which you should watch over and examine the state of every patient when anything abnormal occurs to disturb the regular progress of convalescence. I shall always recollect the case of a young man that came under my notice at the beginning of my attendance on hospital practice. He had recovered from severe typhoid fever, and everything seemed to indicate that he would soon leave the hospital with his health perfectly recovered, when, one day, he complained of not being well, of loss of appetite, and difficulty of breathing. He had suffered no sudden exposure to cold, had no shivering, nor felt pain in the side. I neglected to examine the back of the chest, and sought in vain to account for the source of the symptoms. The dyspnœa soon increased with astonishing rapidity; the patient was a prey to impending suffocation, and did not long survive. What was my regret, when, on opening the thorax, there was seen an enormous purulent effusion filling the pleura! This painful lesson was not lost on me. Many a time have I since discovered, in analogous circumstances, circumscribed pleuritic effusions that might easily have escaped observation. Let not, then, the impression of this fact be effaced from your minds, but let my error be so far profitable to you as to guard you against the commission of similar mistakes.

Of the secondary pleurisies, some may be called *complicated*, the most frequent of which are certainly such as are coincident with tubercular depositions in the lungs. You also meet with cases of gangrenous pleurisy; that is, with effusions from which there is exhaled a horrible fœtor, resembling that of animal substances in a state of decomposition. These cases—the worst of all—are, however, exceptional, and are usually connected with gangrene of the pleura or lungs.

As regards tubercular pleurisies, they are seen to arise under two very different circumstances; for they may occur, and the effusion be produced, when the pulmonary phthisis has reached its last stage; or, on the contrary, the [tubercular?] diathesis becomes potentially developed in the system through the agency of pleurisy. In the former cases, the pleurisy may present such irregular peculiarities as often to lead into error. Thus, old adhesions may be the cause of altering the features of the disease, and force the fluid to accumulate in parts of the chest the most diversified. They have been seen occupying the lateral part, without advancing or receding. In other cases, the effusion has been on the upper surface of the diaphragm, pressing the centre of the lungs upwards. What is more singular still, there are at least two cases on record where encysted pleurisies have occupied the upper part of one side of the thorax, descending as low as the middle part of the chest, and depressing strongly the lung. You see how difficult it might be to arrive at an exact diagnosis, if ignorant of these peculiarities.

We come now to the second form of tubercular pleurisy—that, namely, which developes itself in subjects predisposed to phthisis, but in whom the physical signs of pulmonary tubercles are still uncertain or altogether absent. Well, I begin with our patient, whose case this is. Several reasons lead me to this opinion; and the first is, that the pleurisy is on the right side. It is now a long time since M. Louis first declared this to be the rule,—that when pleurisy is normal and of a good kind, that kind which is always cured, it has its seat on the left side of the chest. My personal experience, which now consists in some hundred cases, confirms this proposition in every particular. I can now say, regardless of any other sign, that when pleuritis shows itself on the right side, the existence of pulmonary tubercles will be found in 95 for every 100 cases. This statement will, no doubt, seem strange to you; but permit me to add, that it was not till I had engaged in attentive and long-continued observation, that I could myself adopt this opinion. It has happened to me, as to most other physicians, to have the care of, and to cure, patients suffering with pleuritis of the right side, and in whom there was no appearance of pulmonary tubercles. But of these patients I have not lost sight, and a time comes when they present themselves again, when there is no room for doubting in such the existence of phthisis, had not the autopsy also come to confirm the diagnosis. I had lately under my care a man of a very strong and robust constitution, in whom I had not the slightest suspicion of the existence of tubercles. In this patient the effusion was considerable, and on the right side. It had now been of some duration, and nothing led me to think that absorption could be effected. I performed thoracentesis, which gave issue to three and a half litres of sero-fibrinous fluid. The operation was followed by the best results: the patient was perfectly cured, and returned to his occupation, which was hard and laborious. I considered his case to be an exception to the rule I have just laid down. But, ere six months passed, he died in my "service" with lesions characteristic of pulmonary tuberculisation.

In our patient there are other signs that come in aid of the diagnosis I have formed. If he has no cough, never spits blood, is not subject to colds in winter, and has never been ill, yet must we not take into account his great emaciation and cachectic aspect, in spite of the very favourable hygienic condition in which he has been placed? Have we not also learned from him that his father died at the age of forty-three years, after a slow and chronic disease of the chest? If we examine the chest, must we not also attach some value, as a diagnostic sign, to the sub-clavicular depression existing on both sides? Lastly; does not percussion reveal a degree of partial dulness on the left side; and have we not noticed the loud and strong respiration, with prolonged expiration, and resonance of the voice and cough? These signs, I admit, if taken singly, have no pathognomonic importance; but, taken collectively, I deem them sufficient to establish our diagnosis. In our next Lecture I shall speak of the treatment.

SERIOUS SCALP WOUND.

By W. F. McMILLAN, M.D. Glasgow.

On the afternoon of Monday, 20th August, 1860, I was sent for to visit a lad, residing about four miles distant, who had sustained a serious accident. I reached the residence of his father as soon as possible, and found the following state of matters:—My patient was in bed, suffering from a wound on the forehead and scalp, of between four and five inches long, commencing about half an inch above the left eyebrow, and running obliquely upwards and backwards. The surrounding tissues were detached from the cranium for fully three inches on each side of wound. There was bare bone for two inches long by half an inch broad. Hæmorrhage to a considerable extent had taken place before my arrival. Besides this, there was a contused wound on left side of head, nearly two and a half inches long. I learned that the lad had been on horseback, having a large nail-box slung on his back, and that the animal had turned the corner of a field more quickly than he expected, and he was thrown off to the one side. In his fall the nail-box reached the ground first, and he hit it with his head, causing the above injuries. I dressed the wound, inserting three stitches in the large and two in the smaller wound, and kept them cool and moist with wet lint; at the same time I placed him under antiphlogistic regimen. The wounds were dressed once in twenty-four hours, and I am happy to say that they healed by the *first intention*, and on the eighth day he returned to his work in the fields, and has continued at it ever since, never having had one bad symptom.

The following case contrasts strikingly with the foregoing:

On Tuesday, the 21st of August 1860, H. G., a young woman, was pushed violently against a wall, and received a wound in the forehead, about an inch and a half long, and three quarters of an inch broad. I dressed it carefully each day, and yet it kept her nearly three weeks from work, she having had considerable constitutional disturbance.

In both cases the wounds were quite clean, and were treated nearly in the same way; and yet the lesser wound (the female's) was about three times longer in healing. It also caused much more disturbance to the system than the larger wound (the man's). It is possible that the diversity in the circumstances of these two persons, as to air, diet, &c., may have had something to do with the difference of time taken to heal their respective wounds: the woman being a weaver, her system may not have been so able to bear up under an injury as that of the young man, who being a farmer's son, and working constantly in the open air, his system was more qualified to effect the reparative process.

Friockheim.

M. Luca has made a chemical analysis of the liver of a patient who died with atrophy of the pancreas. He found glycogenic matter in the liver; showing thereby that the disease of the pancreas had not sensibly interfered with the glycogenic action of the liver. He also found, on examining a mixture of the different substances, solid and liquid, taken from the cavity of the heart, and from the inferior vena cava near the diaphragm, that the mixture contained no free fatty acids, and that the fatty matter was not decomposed. This fact may be explained by the disease of the pancreas, in accordance with the function given to that organ by M. Bernard.

THE SPIRIT OF THE PERIODICALS.

We extract the following article on *Bleeding Hæmorrhoids* from the 'Journal of Practical Medicine and Surgery:'

"Two men suffering from hæmorrhoids were admitted into the Hôtel-Dieu, under different circumstances. One was a vigorous, athletic lighterman, whose inflamed countenance bore testimony to habitual indulgence in wine and spirits. Two years ago he experienced a sense of local irritation and weight about the anus; from time to time he had since observed unimportant sanguineous exudations from the intestinal orifice, and when he entered the wards, the anus was surrounded by protruding venous tumours. Signs indicative of the presence of the molimen hæmorrhagicum were also present, such as increased heat of skin, frequency of the pulse, hypogastric pain, &c. These symptoms were premonitory of a fresh attack, which terminated in the escape of a small quantity of blood. The general as well as the local condition of the subject immediately afterwards began to improve; the tumours faded, and the patient left the hospital. In this instance, the ordinary means of subduing the disease, such as baths, repose, laxatives, and abstinence, were alone requisite. It is obvious that, if this man, who is obliged to pursue his occupations in a standing attitude, could be induced to reform his habits of intemperance, he might look forward to a complete and definite cure.

"The second case was more interesting. The patient was a coachman, and, like other stablemen, he had been in the habit of drinking white wine in the morning, and brandy several times in the course of the day.

"The almost universally prevalent custom among French operatives to drink white wine in the morning fasting, is, in M. Jobert's opinion, one of the most fruitful causes of hæmorrhoids among the working class. The portal vein conveys the wine to the liver, as it does all other ingested liquids; and as this fluid is more irritating when undiluted and unmixed with nutriment, it acts powerfully on the venous system, which it predisposes to inflammation. To this agency of the wine must be superadded the standing attitude, which numerous labourers are obliged to adopt, and both causes combined will be readily conceived to exercise considerable influence on the formation of piles. No valves existing in the portal system, the column of blood destitute of support weighs upon the veins of the rectum, already in a state of inflammation. Hence increased turgescence and irritation of the intestinal mucous membrane, and the consequent production of hæmorrhoids, which M. Jobert considers as mere varicose dilatations of the mesenteric veins.

"Be this theory correct or not, hæmorrhoids bleed, and the blood occasionally escapes from a very circumscribed spot. This was the case in the patient under consideration. The man was tall, pale, anæmic, extremely debilitated, and day and night lost blood from the anus. On two successive days he was carefully examined with a speculum ani; and at a very short distance above the sphincter, M. Jobert discovered a small, circumscribed protrusion, destitute of fluctuation, and even possessed of a certain amount of hardness; it was formed by a brownish coagulum, protecting a venous aperture. This has been described by Amussat as the characteristic sign of the origin of venous or arterial hæmorrhage. If the surgeon, aware of this circumstance, removes the coagulum, blood issues from the vascular orifice, thus clearing up all doubt as to the precise seat of former sanguineous exudations. In this instance, hæmorrhage had recurred frequently since twelve months. On the first occasion it could be assigned to no distinct cause, but had doubtless been induced by local phlebitis and ulceration; a coagulum had probably formed which a motion loosened, blood had again escaped until checked by a fresh coagulum, and so on. The bloodless condition of the patient thus became perfectly intelligible, and the necessity of arresting a cause of exhaustion so perilous to life was manifest.

"Perfect rest, astringent acid beverages, cold

enemas, the extract and syrup of rhatany, a generous diet, and chalybeates, had already invigorated the patient, improved the condition of his blood, and increased the intervals between the hæmorrhages. A more positive assurance of local cure was, however, desirable; it would have been requisite to apply to the venous aperture, with the assistance of the speculum ani, a small actual cautery at white heat, the only efficacious remedy in this instance, and one which M. Jobert has had many opportunities of resorting to with the greatest benefit. The patient, however, feeling better, and probably dreading the operation, suddenly left the hospital; a circumstance much to be regretted, as in his position a recurrence of the hæmorrhage may lead to fatal consequences.

"These two cases induced M. Jobert to enlarge on the treatment of hæmorrhoidal tumours; a subject we have so frequently expatiated on in this journal, that we shall not reproduce his observations on the present occasion. We shall merely say that the Professor generally uses for their removal the actual cautery or the Vienna caustic."

The 'American Medical Monthly' contains a Report, by Dr JOHN O. BRONSON, of Four Cases of of *Vesico-Vaginal Perforations*. We quote two of the cases:

"CASE 1.—*Cured in One Operation by New and Original Means.*—On the 6th of June, 1856, in conjunction with my colleague, Dr C. A. Budd, I was called in consultation to a case of tedious labour. The labour, which had progressed favourably for a short period, was arrested at an early hour in the day, and at seven in the evening we met in consultation. The position of the fœtus was found to be regular, with the head low down. The vagina lacked moisture, and the external organs were greatly œdematous. It was decided to deliver at once by means of forceps, which was accomplished with care and skill by Dr Budd. This was the fifth child of which she had been delivered, none of whom were then living, three of them having been still-born and withdrawn by the forceps.

"The case was left in the care of the attending physician, who, on the fifth day after, again called me on account of a dribbling of urine, of which the patient complained. I found the vesico-vaginal septum inflamed and sloughing where it had suffered compression between the occiput and pubis. I counselled cleanliness and attention to the general condition of the patient, she being of a delicate constitution, and requiring supporting treatment.

"This course was followed, and at the termination of four months the patient was deemed in condition to bear an operation for the cure of the lesion resulting from the sloughing.

"Upon thorough examination, the parts were found perfectly cicatrized. The cervix uteri had been involved in the general inflammatory action, and had in great part sloughed away. To the left of the median line, and one inch from the cervix, a perforation of the vesico-vaginal septum existed, measuring one inch and a quarter in its vertical by three-quarters of an inch in its transverse diameters. Its border was quite regular, and in a healthy state. The question of an operation was decided in the affirmative, and I resolved to perform it on the following principles:

"Preparation of the border of the opening being the first thing requisite, I deemed a vertical excision as usually practised not as conducive to success as if the border was cut to a bevel, taking more tissue from the vaginal wall, thus producing a more extensive vivified surface, without really enlarging the opening. I considered other advantages to attend this manner of operating, as it involved a principle heretofore overlooked or unmentioned.

"When the bladder is collapsed, the opposing surfaces, by every motion of the body or its larger members, are chafing the one against the other, and thus forcing the fluid it is constantly receiving into its cavity into any fissure or crevice, which in a state of rest would be wholly impervious.

"A familiar illustration of my meaning is seen in a fine-meshed sieve, which will hold a considerable quantity of water if undisturbed, but if chafed even but slightly, by the palm of the hand for instance, the water is forced through rapidly and completely.

"By bevelling the border of the aperture, when the sides are brought into apposition the vesical edge is in closer contact than the vaginal, and a slight prominence is formed on the vesical side, which counteracts, in part, the influence exerted by the collapse of the organ. Another fact having an important bearing on this operation I have failed to find heretofore considered. I mean the difference of structure between the vaginal and vesical tissues. The strong muscular structure of the bladder greatly preponderates over the weak muscular tissue of the vagina. There is a difference not only in power, but also in function. The muscularity of the vagina is only active under sexual excitement; whereas, the muscular action of the vesica is stimulated by the presence of anything in its cavity. This difference presents an indication which is met in great part by this method of denudation.

"Coaptation and maintenance of the lips of the wound in contact, with the exact amount of pressure, was the next subject for consideration.

"Rest is a fundamental law of cure, and the more completely it is effected the more successful will be the result after operations upon the vesico-vaginal septum. To overcome direct opposing traction upon the lips of the wound is not all that is sufficient. A sliding of the lips upon one another must be also prevented.

"To meet these indications, I devised an instrument which combined the power of preserving perfect rest to the parts implicated, in overcoming both direct and oblique traction, and the advantage of being readily graduated in its pressure, external to the vulva.

"Having well considered these matters, I proceeded to carry them into practice.

"On the 30th of October, 1856, in the presence of Dr B. Fordyce Barker, Dr C. A. Budd, and assisted by Dr J. H. Douglas, and Mr Farrington, medical student, I operated on the foregoing principles.

"Placing the patient on her knees, with her body flexed forward, and resting upon her shoulders, in the position first recommended and practised by Wutzer, the parts were brought into view by means of the swan-bill speculum or perineal elevator, as also first practised by him.

"First delineating with a sharp-pointed bistoury the extent to which denudation was desired, I proceeded to dissect a continuous strip from the vaginal border of the opening, three-eighths of an inch wide, leaving the vesical tissue barely encroached upon at its extreme edge. This step was readily perfected with bistoury and scissors. All was now ready for the application of the instrument, which was done by inserting the teeth half an inch from the edge of the denuded surface, and passing them between the vaginal and vesical membranes, and bringing them out at points in the denuded surface one-eighth of an inch from the vesical border. The two parts of the instrument were then approximated, and the lips of the wound brought into close contact, and there retained by means of the thumb-screws, perfectly closing the aperture. A catheter was then introduced and secured in place, and the patient, assuming the recumbent position, was left to rest and await the action of nature.

"On the following day, everything was progressing favourably.

"On the 1st of November, the second day after the operation, by a misunderstanding on the part of the attendant, the patient was not visited, and on the following day I found that the catheter had been accidentally removed and the vesica was filled to its apparent limit, and yet the parts were impervious. I drew off seventeen ounces of urine, giving the patient great ease.

"On the 4th of November, the fifth after the operation, I removed the instrument, and found my fondest hopes realised in complete union of the lips of the wound.

"On the 3rd of December, having perfect control over urinary action, and able to retain her water as long as ever, she was discharged from further care.

"CASE 2.—*Spontaneous Cure after One Year and Three Months' Duration.*—Mrs M——, native of Ireland, twenty-five years of age, mother of one child, consulted me in the month of October, 1857, by reason of inability to retain her urine, it being constantly dribbling away. I found upon examination that a perforation of the vesico-vaginal septum existed near the left border of the trigone, about one inch from the neck of the bladder. The opening admitted the passage of a common silver catheter, and had been produced by tedious labour. Operation was proposed and agreed upon, but violent opposition on the part of her husband to anything having the name of *operation* could not be overcome, and it was therefore postponed until after she should have given birth to a child, of which she was then two months pregnant.

"On the 22nd of May, 1858, she was taken in labour, and after twenty-eight hours, without unusual symptoms, gave birth to a female child. From this time, one year and three months from the birth of her first child, all dribbling ceased, and the patient was well. Upon close inspection of the parts, three weeks afterwards, it was found that union of the two sides of the perforation had occurred, apparently by reason of the pressure of the head of the fœtus occluding the aperture for the time being, while Nature put forth her efforts to permanently close the breach."

We will continue our quotation next week.

The 'Lancet' opens with a continuation of Mr HILTON'S Lectures on *Pain*. Dr COOTE also continues his remarks on a case of *Piarrhæmia accompanying Acute Diabetes Mellitus*, which we will quote next week. The same journal contains an article, by Mr WORDSWORTH, on the *Operation for the Relief of Phymosis*. He says:

"Few of the minor operations of surgery are performed in more varied ways than those commonly practised for the cure of phymosis. Some surgeons are content to imitate the Hebrew circumcisors; others simply slit up the prepuce, and, having introduced a few sutures, leave the angular flaps so produced. In infants it probably does not matter very much which course is pursued; provision having been made for the free exposure of the glans penis by a sufficiently large aperture in the prepuce, nature generally adapts the structures nearly to the normal type by a gradual and modified development, so that scarcely any vestige of either the defect or of the operation practised for its relief can be seen in after life. But with men and boys, in whom there is no longer this mode of adaptation, it becomes a matter of more consequence that the operation should leave the structures concerned in the nearest possible condition to that which nature usually produces, as growth and development can no longer compensate the deficiencies of art.

"Under these circumstances, a moment's reflection will suffice to indicate the procedure which will best effect the object in view. The aperture being contracted and rendered inextensible, principally by the rigid mucous layer of the prepuce, it may obviously be most easily enlarged, and with least mutilation and violence of the organic relations, by a curved incision corresponding with its free margin. The frænum and its lateral prolongations into the prepuce will thus be left intact, and the size of the aperture increased at the expense of the dorsal portion of the prepuce. Having, then, decided on the mode of enlarging the aperture, what is the best means of effecting it? After seeing a considerable number of these operations performed by others in the various ways detailed by systematic authors, and from some experience of them myself, I have latterly performed the operation on a plan which, so far as I know, differs from any other, and I believe affords facilities and advantages over all.

"Let us take a common example, in which the aperture has gradually become so small that it may be compared to a pin-hole. The ordinary silver probe with a point may be introduced by drawing forward the prepuce from the glans penis, and passed as high as the reflection of the prepuce from the penis. This being ascertained, it may be pushed through the prepuce a little nearer to its free margin, or at any other part sufficiently distant to allow of the necessary increase of aperture. An ordinary straight needle, armed with a piece of fine silk, should then be passed through the prepuce at short distances, so as to act as sutures. This may be done as follows:—An assistant holds up the probe, and the operator with one hand stretches the prepuce downwards, and with the other transfixes it with the needle in a curved line, reaching from the orifice to the point of puncture, so marking out the portion of the prepuce to be removed. At least a dozen sutures should be passed, and the upper one

should be a little higher than the aperture made with the probe. Then with a sharp pair of scissors cut off the piece of prepuce between the probe and the sutures at the distance of two lines from the latter. An oval aperture, having its long axis perpendicular, will have been made. The centres of the sutures are then drawn upwards and divided, so that each silk forms two, and lightly tied. A little wet lint is wrapped round the penis, and the patient laid on his back, with a cradle to support the bedclothes.

"This operation differs from the French mode of procedure with the fenestrated forceps, principally by substituting a curved line of incision, by which only the dorsal portion of the prepuce is removed, and the frænum left intact; and the scissors allow of a more clean and accurate incision than the bistoury."

Dr CHILD gives some interesting cases on the *Connection between Chorea and Acute Rheumatism*, which lately came under his observation at the Radcliffe Infirmary, Oxford. We quote them:

"CASE 1.—An agricultural labourer, aged twenty-three, admitted July 4th, suffering from a well-marked but not severe attack of chorea. The right side only was affected. This case in itself presented no remarkable feature, except that afforded by the age of the patient, who had had no previous attack. He was treated with sulphate of zinc, in doses gradually increased up to fifteen grains, three times a day, and was discharged, recovered, on the 8th of August. This young man had suffered previously from acute rheumatism.

"CASE 2.—Also an agricultural labourer, aged seventeen. This case was very similar to the last, was treated with the liquor potassæ arsenitis and moderate purging, and recovered rapidly. This lad's father had suffered several times from acute rheumatism, but the patient himself had never before had either rheumatism or chorea.

"CASE 3.—A little girl, aged twelve, admitted August 1st, and still in the house. This case presents some peculiar features. On admission, the attack of chorea appeared to be very severe, and the child was much emaciated; the skin hot, dry, and remarkably harsh; the tongue dry, and the lips cracked. There was a feeble pulse, and great thirst. No history of the fever was extracted from the mother, but subsequently, when sufficiently recovered to speak, the child told us that some children at home had had 'the fever' just before. The child's appetite was good, but she got scarcely any sleep and screamed violently in the night. A day or two after admission, a rash having all the characters of roseola made its appearance. She has improved rapidly under the use of warm baths, diaphoretic doses of antimony, and a generous diet, with port wine and water. This patient has had chorea previously, but not rheumatism; her mother, however, had chorea when herself a child, and also suffered from acute rheumatism about a year before the birth of this child.

"CASE 4.—This is an ordinary, and not very severe, case of chorea, the patient also being a little girl, and not having suffered any previous attack of either chorea or rheumatism. In this case again the mother experienced an attack of acute rheumatism about a year before the child's birth.

"CASE 5.—E. B——, another little girl, of about the same age, was brought to the hospital, on August 29th, suffering from slight chorea, combined with anæmia and general debility. In this case also I found on inquiry that the mother had had acute rheumatism about fifteen years ago.

"*Observations.*—Of the above five cases, which have come to this hospital in the space of scarcely more than two months, Case 2 was under the treatment of Dr Rolleston, the others under my own. Since the year 1850, when the existence of a connection between rheumatism and chorea was announced by M. Sée, of Paris, and in England by Dr Senhouse, much attention has been given to the subject. M. Botrel, in the following year, went so far as to declare that chorea is nothing [illegible] rheumatism of the nervous 'centres.' Botrel's view was not, however, generally accepted; and opinions on the point have varied greatly since that time—so much so, indeed, that one of the latest French writers on the subject (M. Moynier) declares the connection to be nearly accidental, though he himself, inconsistently enough, tells us that, out of thirty cases which he examined, the connection in question could be traced in eighteen. Dr West has never once met with it, nor (he says) has M. Rilliet, at Geneva. It is well known that both diseases are often hereditary; and Dr Begbie was, I believe, the first to point out the existence of a family connection between the two—to show, that is, that it frequently happens that where one member of a family is subject to chorea, another is rheumatic. The cases given above seem to me to point to the conclusion that rheumatism and chorea are 'hereditarily convertible'—*i. e.*, that rheumatism in the parent may descend as chorea to the child. If this should be supported by more extended inquiries, and more especially if the converse should be found equally true, it would, I think, go far to establish, in part at any rate, M. Botrel's theory, that rheumatism and chorea are not similar only, but essentially identical—*i. e.*, that one and the same blood-poison may manifest itself, according to circumstances, as either chorea or as rheumatism. But, whatever may be thought of the theory, the cases seem to me worth recording, if only as showing the connection between the two diseases to exist in them in larger proportion than in any recorded set of consecutive instances with which I am acquainted."

Mr CRICHTON contributes a paper on the prevention of the formation of *Stone in the Bladder.*

Dr ALDRIDGE reports the following case of *Obstruction of the Bowels* from adhesion to the uterus:

"Mrs S——, aged fifty-seven years, the mother of five children. About six months before her death she had a severe attack of flooding, although her menstrual discharge had ceased years before. She was always of a costive habit, and in the month of February, 1859, symptoms of obstruction of the bowels came on, which became more and more aggravated up to the period of her death on the 10th of April following. For some weeks before her decease she had stercoraceous vomiting, the ejected matters being of a yellowish colour, watery, and having a strongly fæcal odour. She seemed to die gradually of exhaustion.

"*Examination two days after death.*—(The abdomen only was examined.) On opening the abdominal cavity, the intestines were seen to be smeared with a yellowish-coloured, watery, offensive matter, similar to that which she had vomited during life. This fluid must, therefore, have escaped into the peritoneal cavity through some hole in the gut. However, it cannot be said that this rupture of the bowel occurred during life, because the texture of the lower part of the small intestine was found to be so extremely soft and friable that it was rent by the slightest touch. In some parts it was gangrenous. It is, then, more than likely that the tear may have taken place after death, either by the pressure of gas developed in the bowel, or by movements of the body, or while opening the abdomen. The small intestine was seen to be very much distended, particularly the lower portion, which was of enormous diameter, nearly equal to that of a normal large intestine. The coats of the ileum in nearly its whole length were in a high state of inflammation. Near the lower end, approaching the cæcum, were many dark-coloured patches, some as large as a two-shilling piece, others smaller, where the whole thickness of the intestinal wall was perfectly gangrenous. The texture of the gut for several feet above the cæcum was so friable, that on moving one coil upon another it tore at various points. In the upper part of the small intestines was found the same yellowish-coloured, watery, fæcal matter that the patient had vomited during life; lower down the contents of the bowel became more consistent; and for several feet from the lower end of the ileum the latter was enormously distended with tenacious, yellowish-coloured fæces, very much resembling putty. The cæcum and large intestine were nearly empty, only a few knots of hardened fæces being found in the latter. In the lower end of the ileum, therefore, the obstruction was seated. On careful examination, the latter was seen to be dragged down into the cavity of the pelvis, and to be firmly adherent to the back wall of the uterus. When the small intestines and the contents of the pelvis were removed from the body, the state of matters could be clearly seen. About six inches from the ileo-cæcal valve, the ileum had become firmly adherent to the posterior wall of the uterus—rather towards the right side—and to the right ovary. The gut at the adherent point made a sharp turn towards the cæcum. Accordingly, everything requiring to pass through this part of the bowel had to travel along its canal bent almost at a right angle. The calibre of the ileum at the attached point seemed smaller than normal, but not much so. It is obvious that this sharp bend in the canal of the gut must have tended very considerably to retard the passage of the fæces through it, and, the latter having been hard and dry, as is usually the case in persons of obstinately costive habit, it can easily be understood how stoppage to the passage of the contents at this point occurred. Once commenced, such an obstruction would only become aggravated in the course of time by the gradual accumulation of fæces above it, and by the strong muscular efforts of the bowel to propel the contents onwards, as happened in this case, in which, during life, the violent peristaltic action of the intestines could at times be distinctly seen. It is not unlikely that if the patient had at a sufficiently early period overcome the tendency to constipation by keeping her bowels in a rather relaxed condition, the obstruction might have been averted, or at all events delayed. On removing the uterus from the body and cutting it open, the whole of the organ was seen to be one mass of epithelial cancer (cancroid), thus accounting for the floodings which the patient had some months before death, and also, in all probability, for the adhesion of the ileum to its posterior wall, as above described. The cancroid disease having implicated and eaten into the whole thickness of the uterus, even to the serous covering of the same, peritonitis seems to have been set up at this point, and to have thus occasioned the attachment of the loop of intestine to it. The coats of the ileum for an inch or two above and below the adherent part seemed to be perfectly healthy. The adhesions between the small intestines and the uterus were very firm, and must, therefore, have existed for a considerable time, perhaps for months.

"At what period the cancroid disease of the womb began it is of course impossible to say, but that it had already attacked the uterus six months before the fatal termination of the case is evident from the occurrence of severe flooding at that time. If obstruction of the bowels had not supervened, and thus put an end to the patient's existence, it is very probable that ultimately a fistula between the uterus and ileum might have taken place by the extension of the cancroid disease through the adhesions and through the coats of the gut."

Two cases of *Idiopathic Tetanus*, treated by Indian hemp, are reported by Dr FARRAGE.

We extract the following article, by Mr BARNARD HOLT, on *Allarton's Operation*, from the 'Lancet' of the 8th inst.:

"The main objections which have been hitherto urged against its performance have been in reference to the size of the stone and the enlargement of the prostate gland, the consequent difficulty of extraction, and the effect of forcible dilatation on the neck of the bladder. Having lately performed this operation three times, where these difficulties were prominent features in each case, I desire to record the results.

"J. R——, a child aged eight years, was admitted into the Westminster Hospital under my care, April, 1860, suffering from stone in the bladder. The symptoms had existed for eight months prior to his admission, and consisted in difficulty and frequency of micturition, which required considerable straining to effect; occasional passage of bloody urine, and, but rarely, pain at the extremity of the penis. The boy having been placed under the influence of chloroform, a sound was passed to the neck of the bladder, where its further progress was arrested by some foreign body, which a slight amount of pressure sufficed to displace. The sound being thus fairly introduced, a stone was immediately detected, which, from the extent of surface traversed, appeared to be large.

"I decided on performing Mr Allarton's operation. On May 8th, while under chloroform, a staff as large as the urethra would admit was

introduced, and the stone immediately detected. The child was now secured in the ordinary manner, and the forefinger of the left hand being passed into the rectum, the exact situation of the prostate was ascertained. A sharp-pointed and somewhat triangular knife was now thrust into the mesial line of the perinæum, with the back towards and about three lines in front of the anus, the finger in the rectum guiding the knife, and preventing its being wounded. An incision was now made directly upwards, and the groove of the staff cut into by opening the urethra immediately in front of the prostate; and the knife was now run backwards and forwards to a slight extent so that it might be fairly divided, the tegumentary opening being enlarged as much as appeared necessary in its withdrawal. The forefinger was now removed from the rectum, and passed into the wound, with the nail in the groove of the staff, which thus formed an accurate guide for the director, which, being made with a handle at right angles, was passed along the groove into the bladder. The assistant was now directed to pull the staff gently but firmly upwards towards the symphysis pubis, whilst I pulled the director gently downwards; and the forefinger of the left hand being passed between these two instruments, was gently wormed between them with a twisting motion, dilating the parts as it proceeded, until the neck of the bladder was reached, when both staff and director were withdrawn, and the dilatation was continued still further by rotating and moving the finger from side to side. The forceps were now introduced upon the finger, which was withdrawn as they passed into the bladder, so that to the present time no urine had escaped. The stone having been detected, the blades of the forceps were separated, when the gush of urine carried it between them, and with gentle traction it was removed. As was anticipated, it proved of considerable size, measuring two inches long and one inch wide, and weighing 240 grains; it was of the triple phosphate variety. The hæmorrhage was of the most trifling description, and beyond the smarting attendant upon a wound he had hardly suffered anything. There was no involuntary escape of urine after the operation, but it was passed at will, for the first week through the wound, but afterwards per urethram. Eight days from the operation he was walking about the ward, and in a fortnight was discharged cured.

"The second case occurred in a spare, feeble man, aged sixty-five, who had suffered from stone for four years prior to his admission. The urethra admitted a full-sized sound, and the prostate was perfectly health. The bladder was, however, considerably contracted, not holding more than four ounces of urine; and the stone, which was readily detected, was large and dense. The same proceedings were adopted as have been already described; but the stone, proving even larger than was anticipated, eluded the blades of the forceps. A large pair were consequently had recourse to, and the stone removed. It was found to measure two inches and a quarter long by one inch and a half in breadth, and weighed 570 grains. It was of the oxalate of lime variety, coated with phosphates. The patient was comfortable during the evening, and passed his urine at will. He was, however, seized in the morning with a rigor, and died suddenly.

"The post-mortem was made twenty-eight hours after death, and the bladder having been removed, the incision was found to be exactly in front of the prostate. The bladder was now cut into, and the mucous membrane corresponding to the neck was found to be congested and slightly torn, not, however, extending into the prostate gland, and much less than is met with in the lateral operation. The kidneys were in an advanced stage of cystic disease; the heart fatty; but the other organs were healthy.

"The third case occurred in my private practice, in the person of a gentleman aged seventy-five, of spare habit, who had suffered from diseased prostate more or less for the last eight years, during which time he had occasional hæmorrhage, sometimes slight, and sometimes sufficiently severe to call for the exhibition of gallic acid, the bleeding being at all times provoked by any extra walking or jolting exercise. Although there was no pain at the extremity of the penis after micturition, yet the symptoms to some extent simulated those of stone, and the bladder was from time to time carefully examined both by myself and others, without, however, detecting any foreign body. Early in 1859, while at his seat in the country, he was attacked with inflammation of the bladder, characterised by rigors, great frequency of micturition, spasms of a most violent character, and occasional pain at the extremity of the penis, the urine depositing the usual amount of muco-purulent, tenacious deposit. Suitable remedies were had recourse to, and in the course of three months he recovered; the spasms entirely subsided, the urine regained its healthy character, but the difficulty of expulsion had so far increased as to prevent his passing more than an ounce at a time. He was therefore directed to pass his own catheter three or four times in the day and night, which he accomplished without either difficulty or suffering. In the winter of 1859, being again in the country, he had another but more severe attack, which apparently arose from standing on damp ground, and it was evident, from a sudden discharge of pus and extreme tenderness of the prostate, that an abscess of that gland had formed and burst. His symptoms were now very distressing, the bladder much more irritable, and the pain at the extremity of the penis more decided; and being now unable to pass any urine naturally, he was compelled to rely entirely upon the catheter, which was passed every three hours. The bowels were daily relieved by enemata. The horizontal position was maintained, and all the known remedies had recourse to, belladonna, copaiba, and chlorodyne giving the greatest relief.

"In the spring of the present year he was removed to town, the frequent and almost irresistible urgencies continuing, and the pain at the extremity of the penis being more acute. Opium, in the form of suppositories, was the only drug that now afforded the slightest relief.

"On Sunday, June 15th, after violently straining at stool, the bladder became more than usually irritable; and being requested to pass his gum catheter, I immediately detected a calculus, rough, and, so far as could be ascertained by such an instrument, not very large. A consultation with Mr Arnott and Mr Cæsar Hawkins was held; and as lithotrity offered no chance of relief, Allarton's operation was decided upon.

"On June 27th he was placed under the influence of chloroform, and the operation, as already detailed, was performed. Not the slightest difficulty was experienced in reaching the neck of the bladder, but the size of the prostate prevented the interior being explored, or the stone being felt with the finger. The forceps were consequently substituted, and being buried to a considerable depth, a stone was caught and removed, proving large, smooth, and polished. Another was sought for and removed, which bore an accurate resemblance to the first. It was, therefore, evident there must be a third, which, after slight difficulty, was also included between the blades of the forceps, but being larger than either of the former ones, it required some little patience and gentle traction to remove it. The parts, however, yielded, and the third, somewhat roughened, stone was now abstracted. The first measured 1⅝ in. by 1¼ in.; the second, 1⅝ in. by 1⅜ in.; and the third, 1⅝ in. by 1¼ in.; the weight of the three being 960 grains. The incision was insignificantly small; the hæmorrhage very trifling; and my patient being now placed in bed, shortly recovered from the effects of the chloroform, and simply complained of the slight smarting of the wound. The neck of the bladder retained its contractility, and there was not any involuntary escape. The suppository was introduced as usual; and, excepting when the urine was withdrawn, he slept tranquilly. For the first three days he progressed in the most favourable manner; the intervals were increased, the catheter being introduced every four, instead of every three, hours; the spasms were less frequent and less intense, and he was nearly relieved from the pain he had previously experienced, when, on the fourth day, he was seized with rigors, extreme and urgent pain in the region of the stomach, vomiting, and his pulse, which was exceedingly weak, rose to 130; skin hot; countenance anxious; and the urine presenting an appearance of bloody jelly. Opium and stimulants were administered, the bladder was injected with tepid water, and he rallied. He, however, continued exceedingly ill for three or four days, when the attack gradually subsided, the urine became more natural, but the spasms of the bladder recurred; and fearing the possibility of a calculus having descended from the kidney, he was again examined, under the influence of chloroform, without, however, discovering any foreign body; a roughness was detected with the gum-elastic catheter, but not with the sound, and in all probability depended upon a calcareous coating of some portion of the mucous membrane; indeed, this was subsequently ascertained to be the case, for, upon introducing a lithotrity spoon, a portion of gritty matter was removed, and eventually the corresponding mucous surface, coated with phosphates, came away in the eye of the catheter. Small particles of the same deposit have from time to time escaped. The frequency and spasms have now entirely subsided; he is enabled to pass per urethram from two to three ounces of urine; the bladder will retain from ten to twelve ounces; the wound has so far healed as to be hardly perceptible, and when necessary he can introduce his own catheter. The bowels, which have hitherto required enemata of water, have acted naturally since taking the confection of senna; and an examination per anum proves the prostate to be diminished in size. He is daily gaining flesh and strength, and when the weather will permit drives out.

"The present cases have been described simply as examples to prove that large calculi and an enlarged prostate form no bar to the operation, and, as far as they go, establish the facility with which a large stone can be removed without injury to the neck of the bladder. It is true that the mortality is about the average; but as in the fatal case there was probably sufficient cause in the state of the kidneys and heart superadded to the rigor, from which persons in advanced years frequently die, I cannot consider it as in any manner militating against the operation.

"The case of the boy was interesting in showing how circumstances may alter and modify symptoms generally relied upon as characteristic of stone. The pain at the extremity of the penis was the exception and not the rule, and evidently depended upon the stone generally occupying the same position and requiring to be displaced before the sound could be fairly introduced. The diagnosis was correct in reference to its size, which it must be admitted very far exceeded the average of such cases at such an age.

"In the second case, the facility with which the stone was detected, and the ringing sound, afforded sufficient evidence of its size and density to preclude any advantage from lithotrity.

"The third case must be considered as the most important of the three. The size of the prostate—which did not permit the finger to reach the bladder after the necessary incisions had been made—the long duration of the disease, the inability to pass any urine without the introduction of a catheter, the irritable state of the bladder, the emaciated condition of my patient, and the presence of three such very large calculi, were sufficient to test the operation to the utmost. I may mention that this gentleman had been subject to severe bilious attacks which very much resembled the one that supervened on the fourth day, and that the issue of the case proves the symptoms to have depended upon a deranged liver.

"I have described the operation as it was performed; and although the precaution of introducing the finger between the director and the sound may not be absolutely necessary, yet I am convinced it simplifies the operation to such a degree that no surgeon of common intelligence need fear undertaking it. The extraction of the stone requires care and gentleness. A minute lost is a minute gained, if a large calculus can be removed through the neck of the bladder without injury; and I feel convinced this can always be effected if the necessary care is exercised. In almost all the descriptions of the ordinary forms of operating, the direction is, to have a large external wound. Such is not necessary; and if a stone can be removed, without bruising, through a moderate wound, it is certainly better than making a large one.

"From all that I have yet seen of Mr Allarton's operation, I consider it a most valuable one: the wound is less; the hæmorrhage is less; the constitutional disturbance is less; there is no chance of infiltration of urine; and, as a matter of comfort to the patient, the ability to retain the urine is of the utmost value and importance."

Mr Brent makes some observations, in the

same journal, on *Fatal Effects arising from Enlargement of the Thymus Gland in Children.* The mode of death appears to be by convulsions and sudden spasmodic closure of the glottis, arising from the pressure upon the adjacent nerves by the enlarged gland. Mr Brent observes :

"The thymus in the human subject increases in size very rapidly after the seventh month of fœtal life, and at birth at the full period has commonly varied, (as stated in the 'Cyclopædia of Anatomy and Physiology') from 84 to 240 grains in weight. At nine months afterwards, according to the same authority, it is found to be about 270 grains—4½ drachms—in weight; at a variable time after which period it progressively declines in size. I find that Kopp states his having noticed several cases of suddenly fatal dyspnœa, occurring in children in whom the gland was found of large size, and that he concludes there is some essential connection between the glandular enlargement and the suffocative paroxysms. Dr Copland ('Dictionary of Practical Medicine,' art. Larynx and Trachea, p. 679) has remarked, however, that Mr Hood, of Kilmarnock, was the first to direct attention to enlargement of the thymus gland, and its influence in producing morbid closure of the glottis, with suffocation. But he does not even hint that the effects of the preternatural enlargement are other than mechanical—such as pressure on the veins at the top of the chest, inducing congestion and effusion in the head ; and no supposition appears to be entertained by him that an unusual size of the gland is accompanied by an increased nervous susceptibility. I have been led to conclude, from the history of the cases that have come under my notice, that a correlation exists between the size of the thymus gland and the development of the brain and impressibility of the nervous system. In such instances of sudden death coincident with abnormal enlargement of the thymus as have fallen under my observation, the children have been noticed as peculiarly forward and intelligent for their ages. The work first quoted above states that 'absence of the gland has only been observed in cases of acephalism, where the brain and many other parts have been simultaneously deficient.' If it be true, then, that the greater size of the thymus gland has anything to do with the greater development of the nervous matter, force, or excitability, there will be a double reason why an unusual enlargement, or a non-absorption, of that body should occasion suffocative dypnœa,—namely, both from the greater excitability produced, and the inordinate pressure exercised by the gland in a state of turgidity."

The 'Medical Times and Gazette' opens with M. Claude Bernard's Lectures on *Experimental Pathology.* The present part contains some observations on the Effects of Woorara. Dr Wynn Williams reports *Two Cases of Epilepsy,* in which the operation of tracheotomy was performed. He says :

"As there have not been many recorded cases of epilepsy in which the operation of tracheotomy has been performed, as recommended by the late Dr Marshall Hall, the particulars of the two following cases may possibly be of some interest.

"The first case is that of T. P., aged eighteen, son of a cabinet-maker, who consulted me in September, 1855, on account of epileptic fits, for which I had attended him from time to time since he was ten years of age. The fits, to which he was liable at all hours of the day and night, had lately increased in frequency and duration ; and it appeared not improbable that they would in a short time have rendered him idiotic. He had tried every remedy likely to benefit him, without having derived any permanent relief. He had, it is true, derived temporary benefit from several remedies prescribed ; but the benefit, if, indeed, it can be considered such, was merely illusory, as the paroxysms had only been postponed to recur in greater severity. It seemed as though the medicines administered had prevented the paroxysms breaking forth until the system had become charged, so to speak, with a number of small paroxysms, which, when united, became strong enough to obtain the mastery, and had then broken forth with redoubled fury. The same effect I have seen produced in other cases.

"Such being the state of my patient, I proposed to his parents to open his trachea, and they, as well as the patient himself, willingly assented.

"On September 10 I proceeded to operate. The patient was placed in a chair, my assistant holding back his head, so as to draw out, and make tense, the trachea and its coverings. I then plunged Mr H. Thompson's tracheotome into the trachea, between the first and second rings,—gave a few turns to the screw to separate the blades,—with very little difficulty introduced the tube between them, and withdrawing the tracheotome, left the tube in the trachea. There was not much blood lost during or after the operation. Unfortunately the tube, on the following day, slipped out, and I was unable to reintroduce it without the assistance of the tracheotome ; but on carefully inserting this into the opening, and dilating it by means of the screw in the blades, I easily got the tube between them into the windpipe. For four or five months after the operation I thought my patient would really have been benefited by it. The fits became far less in frequency and severity ; indeed, he at one time remained several weeks without a fit at all. My hopes, however, were again doomed to be blighted. In six months the fits began to recur nearly as often as before the operation. He wore the tube in the trachea about three years, readily taking it in and out himself. I then removed it ; I saw him a few weeks ago ; the opening is still patent, and he breathes freely through it. He goes about and assists his father a little in the workshop. It is possible that this case might have terminated more satisfactorily had not the patient been addicted to habits of intemperance, as I afterwards learned he was, both previous to and after the operation. Had I been previously made aware of this circumstance, I should not have proposed the operation.

"The second case is that of T. F., aged twenty-five, a quarryman, who consulted me in July, 1856. He had been subject to epileptic seizures in the night for many years, but had only been subject to them in the day for two years. He had in consequence been obliged to relinquish his employment. He had undergone a good deal of treatment previous to coming under my care. His object in coming to me was that I might perform the operation of tracheotomy upon him, he having heard of the previous case. Considering him a good subject for the operation, I, on July 9, proceeded to operate in the same manner as in the preceding case. I do not think half-a-dozen drops of blood were lost. The patient went on very satisfactorily after the operation. The epileptic seizures became gradually less severe and less frequent, and for the last two years he has had no attacks during the day-time, and only very slight ones at night. I saw him a few weeks ago in apparently good health, although he informed me he had occasionally, though very rarely, slight fits when in bed. He now goes about by himself, and works in the fields, but has not ventured to resume his work in the quarries. He still wears the tube in his windpipe, and will not hear of its being left out, for fear the hole should close up. Both he and his friends firmly believe he has been benefited by the operation."

Dr T. A. Carter contributes some suggestions for the improvement of *Paracentesis Abdominis* in cases of Ascites, which we will reproduce next week.

Dr Candy reports, in the same journal, the following case of *Puerperal Convulsions* in a Primapara :

"Mary Ann C., aged 20, residing in Great Barr street, Birmingham, was taken in labour of her first child on the evening of January 4. I was first sent for the following morning. I found my patient was a stout, plethoric young woman, of a nervous temperament, but there was nothing about her general aspect to cause me any anxiety as to the successful termination of the case. On making a vaginal examination, I found the os uteri quite high up in the pelvis, and about the size of a sixpence, and the labour pains were regular but feeble. I ordered her ol. ricini ℥ss, and took my leave. About eight p.m. in the evening I was sent for again, but found that the process of dilatation had gone on very slowly, the os being a little larger than a shilling. The pains being feeble, and my patient anxious for sleep, I gave her tinct. opii, ℥ xl., and ordered her to be put to bed, hoping that, after a few hours' sleep, labour would progress more rapidly. About half-past eleven at night I was sent for in great haste, as my patient had been suddenly taken sick, and shortly afterwards had a fit, in which she bit her tongue. This was soon followed by a stronger attack, which induced her attendants to send for me in such haste. I found her in a semi-conscious state, with rather a quick but feeble pulse, and complaining of pain across the forehead. I applied rags dipped in cold vinegar and water to the head, which soon brought her round, and she was able to walk gently about the room. Labour had made but little progress, and finding my patient wished to sleep, I gave her tinct. opii, ℥ xx. ; and after waiting two hours, I left her comfortable. The next morning, between eight and nine, I was again summoned, as the fits had returned after she awoke from a sound sleep. Finding such to be the case, I asked Dr Warden, the Honorary Surgeon for the district, to accompany me, being duly provided with instruments, if necessary. We found her in a semi-conscious state, with the os uteri fully dilated, and the head of the child low down in the cavity of the pelvis. Dr Warden and myself agreed that it would be desirable to terminate the labour as soon as possible, so accordingly the long forceps were applied by him ; but almost directly afterwards she had another fit, during which the head was delivered ; the shoulders and breech were expelled during the next pain. The child (a male) was remarkably well developed, and appeared asphyxiated, but rallied on the application of cold water sprinkled on its face and chest. About five minutes after its birth the mother had another rather severe fit ; but finding her pulse rapid and feeble, I judged it improper to bleed her, but trusted to the application of cold to the head, and allowed a free ventilation through the room. The placenta was expelled naturally, in about ten minutes, and there was little or no hæmorrhage. During the next hour she had several severe fits, but after the last she fell into a dull, heavy state, from which she did not quite recover till four or five o'clock in the afternoon. I remained with her for two or three hours, but finding the fits had left her, giving directions for the application of cold to the head to be continued and the room to be darkened, and as soon as consciousness returned to give her some beef-tea or arrow-root.

"On calling to see my patient the following morning, I found she had passed a quiet night, having slept three or four hours. She complained of severe pain across the forehead, and a dimness of sight, the results of the nervous disturbance and altered circulation through the brain. I prescribed an aperient mixture, containing magnesia sulphatis ℥j., infus. senn. co. ℥iv. ; infus. gentianæ co. ℥vj., of which she was to take three table-spoonsful every four hours, and a pill containing hyd. chloridi gr. iij., pulv. opii gr. j., h. s. s.

"January 8.—Her bowels have been freely opened, the pain in the head is relieved, and her vision somewhat clearer. I drew off some of her urine to take home with me, for the purpose of ascertaining the presence of albumen, but I could not discover a trace of it after careful examination.

"10th.—The pain in her head has nearly gone, and there is a tolerable amount of milk in her breasts. She complains of a troublesome cough, which causes an increased flow of the lochial discharge. I ordered tinct. camph. co. ℥ss., æther chlor. ℥ij., syrupi tolut. ℥j., ex decoct. Senega ℥vij., two table-spoonsful three times a day.

"12th.—Her cough is not so troublesome, but her headache has returned. Tongue foul ; pulse 130, sharp and full. Ordered her liq. ammon. acetatis ℥iv., vin. ant. pot. tart. ℥ij., mist. camph. ℥iv., two table-spoonsful to be taken every four hours, and a powder of hyd. chlor. gr. iij., pulv. rhei gr. xv. at bed-time.

"13th.—She is much better to-day ; the bowels have been freely opened. To continue her mixture.

"16th.—She got up yesterday for an hour or two, but found her head became giddy on walking.

"In conclusion, suffice it to say she is going on favourably ; and if the headache returns, she finds relief from taking some of her aperient mixture.

"*Remarks.*—1. I have my doubts whether the fits were induced by the opium I administered during labour, or whether they resulted from exhaustion consequent upon a lingering first stage of that process. 2. The case is interesting from the fact of the absence of albumen in the urine, which has been observed in many cases. 3. In

the rapid recovery of the patient. 4. In the simplicity of the treatment, compared with that which would be adopted by many in similar cases."

Dr SKINNER concludes his paper on *Deodorization in Obstetric Medicine*, which we extract. He says:

"While in attendance upon a lady during her confinement lately, I observed her snugging the bedclothes under her chin and around her neck. I asked her if she felt cold; she replied no, but that she did so in order to enable herself to breathe a purer air than that coming from beneath the bedclothes. Upon hearing which, I immediately bethought myself of a deodorant of the lochial discharge, and for this purpose I instituted a number of experiments with oil of tar and other well-known deodorants.

"*Deodorant Preparations.*—It would be needless for me to give the details of the various means adopted and of the different substances used, so I shall content myself with stating the composition of a powder which I have found in every way well suited to the purpose:—Calcined oyster-shells, lb j.; oil of tar, gr. lxiv.—Mix. This powder may be variously applied; the following method will be found effectual, if not the best that can be adopted:—One table-spoonful of the powder is to be mixed with from two to four table-spoonsful of the finest dry bran, and spread between the folds of the ordinary pudendal napkin, so that one ply only shall be left between the powder and the patient; the napkin may be stitched along either extremity if required on account of the escape of the powder; and it is to be pinned before and behind to the ordinary obstetric binder. The powder and napkin must be renewed as often as the nurse thinks proper.

"The advantages of this powder over that of any other, and over the much-talked-of one of MM. Corne and Demeaux in particular, is,—1. That it does not cake or set, and adhere to the napkin-like powders prepared from the sulphate of lime. 2. That its absorbing property is not inferior to, nor is it more caustic than, those prepared from sulphate of lime. 3. That powders prepared from sulphate of lime and tar, or oil of tar, retain the peculiar penetrating odour of tar; whereas the powder prepared from calcined oyster-shells and oil of tar has not any smell of tar, but a mild, agreeable, and fragrant smell of the finest oil of peppermint; and although the oil of tar is so altered in smell by the calcined shells, its deodorizing property is rather increased than otherwise.

"*Practical Remarks.*—The experience I have had of this powder warrants me in making the following remarks:—If the application of the powder is properly managed (and it only requires the exercise of common sense), as soon as the lochial discharge comes in contact with the napkin, it is deodorized; not only so, but from the great affinity which the lime has for water, the discharge is rapidly absorbed towards the particles of bran, which in their turn act the part of a sponge, besides extending the deodorizing surface. When the powder is used in combination with proper ventilation and attention to cleanliness, the napkin, the bed, the patient, and the apartment will be found to smell quite sweetly, so that the most fastidious could not find fault.

"The nurse who was in attendance upon the lady previously alluded to, and who has seen twenty years of service, informs me that the napkins are generally put into a tub of water to steep before washing, that the water has invariably a most offensive smell; but in the present case, the first in her long experience, the tub, water, and napkins were all equally free from smell.

"I think it proper to give a practical hint here, and nurses should be informed of it—namely, that it is necessary to shake the loose powder out of the napkins before putting them into water, and they ought to be rinsed out in hot or cold water once or twice before putting them to the wash, because the lime will so harden the water that it will be impossible to get a lather with any amount of soap. It may be supposed that the quicklime will injure the napkins or the patient: there need be no fear of either accident, as no such misfortune has happened hitherto. The powder may be placed upon the tongue without producing any caustic effect; besides, I beg to state that the oyster-shells are not thoroughly calcined—they are simply rendered red-hot for one hour in an ordinary fire, without any blast.

"There is one other purpose to which I apply this powder, mixed with bran, namely, the deodorization of fæcal matter, particularly if *en masse*. All that is necessary is, that the surface shall be covered with a layer of the powder; the instant that this is accomplished, all smell ceases as if by magic.

"*Liquid Deodorant Preparation.*—For the deodorization of liquid fæces, or where a fluid form is preferable, as, for instance, as a vaginal injection in cancer of the uterus, I use the following preparation; and one great advantage of it is, that it may be dispensed by chemists, the same as any other prescription: ℞ Tinct. camphoræ, tinct. myrrhæ, āā ʒiij.; lin. saponis, ʒij.; acidi acetici glacialis, ℥xx.; ol. picis, ʒj. Add the liquids in the above order and agitate. The product ought to be of a pale sherry-wine colour, and perfectly clear. Each teaspoonful contains about ten minims of oil of tar.

Rationale of the Preparation.—The tinctures of camphor and myrrh dissolve both tar and the oil of tar; the myrrh makes the camphor much more miscible with water, and the soap causes the whole to mix more readily with water. The camphor, myrrh, rosemary, and the acetic acid render the strong odour of the oil of tar not only less objectionable, but positively agreeable. The proportions in the formula are the result of very many careful experiments.

"*Directions for Using the Preparation.*—1. One teaspoonful of the tincture added to a liquid stool, and slightly agitated, however fetid, it is deodorized instantly. Solid fæces require sufficient water added to cover them. 2. One teaspoonful added to a pint of water, and briskly shaken for a few seconds, forms tar-water, or a deodorant lotion, gargle, or vaginal injection. The atmosphere of a room may be deodorized in a few seconds by moistening a towel with this lotion and waving it about the apartment, or by evaporating or burning a teaspoonful of the tincture in a saucer or plate. 3. One teaspoonful added to a pint of water forms an invaluable enema, the chief advantage of which, in a lying-in chamber or sick-room is, that it deodorizes the stool before it is passed into its extra-intestinal existence. (For this exceedingly ingenious application of deodorization, I am indebted to my much-esteemed friend Dr Andrew Fyfe, of this town. As I have already tried the plan, I can state that the effect has been completely successful.) 4. Stools requiring to be kept for Medical inspection, whether in hospital or in private practice, may be made perfectly free from smell by adding to them a teaspoonful of the tincture.

"*Practical Remarks.*—Let me add one or two remarks on other conditions in which I have used both the Powder and the Tincture. (a) In cancer of the uterus or rectum, when the passages become blocked up by cancerous deposition, and when deodorant injections and suppositories are used at a disadvantage, the powder mixed with bran and used as directed for the *post-partum* management of labour, already described, leaves almost nothing to be desired. (b) In cases of incontinence of urine from organic disease, from malformation or functional derangement of the bladder in the female, the powder, used as directed, will be found to be a *sine qua non*. It dries up both the urine and the discharges, and deodorizes them at one and the same time. As a matter of course, fresh powder and napkins must be renewed, but not nearly so frequently as by any other plan. (c) In some forms of leucorrhœa and menorrhagia, until the condition is cured on which the loathsomeness of the discharges depends, and in some cases of healthy (but fetid) catamenia in strumous subjects, I have found the powder a great boon to the female. When the stools of infants are offensive, the same simple means, only using the nippen or diaper cloth instead of the pudendal napkin, will effectually deodorize them. (c) In puerperal fever, when there is a fetid discharge, I should undoubtedly use vaginal injections of tar-water as well as the powder; and deodorizing enemata, if the bowels require moving. (f) In the consulting and dissecting rooms, tar-water as prepared in direction No. 2 will be found a most agreeable and effectual deodorant for the hands, when used with a little soap and soft or warm water; and a bottle of such tar-water poured down any bad-smelling waste-pipes, or such like, will render good service. (g) As an injection into the veins to preserve subjects for dissection, I think that water saturated with the tincture or the oil of tar, mixed with soap and water, would be certain to deodorize, if it did not stop decomposition; but as its deodorizing action depends chiefly upon its power of stopping decomposition, I almost feel certain of its success in this particular; it only requires a trial. I have in my possession a uterine fibroid polypus and an aborted fœtus with the secundines, in the highest state of preservation in nothing but tar-water (Aqua Picis Liquidæ D). When they were first put up as wet specimens, two months ago, decomposition had already begun; but the instant that they were immersed the smell disappeared, because the action of decomposition was stopped. One great advantage in the use of tar-water as a preservative fluid is, that it has no action on the tissues. If it be found successful for dissecting purposes, there is one thing certain, that it will neither corrode the scalpel, like the ordinary metallic solutions, nor will it be found objectionable on account of its smell, like solutions of creosote. (k) In incontinence of the fæces, from whatever cause, the powder and a napkin will be found of the greatest benefit.

Dr FIGG's paper on *Turning in all Cases of Labour* is continued in the same journal.

We extract from the 'Dublin Hospital Gazette' the following case of *Enormous Urinary Calculus*, reported by Mr J. HAMILTON:

"Mr Hamilton, in presenting a calculus of immense size formed in the human bladder, stated that the specimen, with some notes of the case, had been transmitted to him from Dr Crane, of Wexford.

"The patient was a young man of about twenty-seven years of age, who had, previous to his being attacked with this disease, always enjoyed good health; but two years before his death he got a severe fall in a ploughed field, and subsequently felt acute pain in the pubic region, followed by painful and difficult micturition, irritability of the bladder, and other symptoms of stone. He did not, however, apply for medical aid until about two months before his death. At that period he was seen by Doctors Goodall and Boxwell, of Wexford. He was carefully examined by these gentlemen, and a stone at once detected in the bladder of immense size, the bulk of which could be easily felt by manual examination over the pubis and by the finger in the rectum. In fact, so large was the calculus, that the sound could not be passed farther than the neck of the bladder, where the instrument struck against it and was stopped. When the question of surgical treatment was mooted, and whether any means of ridding the man of the calculus could be entertained, he got alarmed, and left the infirmary. He afterwards went into the workhouse, where in a few days he died. On the entrance of this man into the workhouse, he was examined by Dr Crane, who also detected the immense size of the stone. It should be observed that, during a long period previous to this man's death, there was an incessant stillicidium, or oozing away of urine from the bladder. The urine seemed to pass off as soon as secreted, and dribbled away without pain. The post-mortem examination was made by Drs Goodall, Boxwell, and Crane.

"On slitting open the urethra and bladder, it was found filled with the stone closely adherent to it, the stone occupying the entire cavity of the bladder, and so closely that it was most difficult to get it out; it required much force, using the handle of a forceps, to prize the stone from its adhesion to the inside of the bladder.

"The bladder was much thickened, and the mucous membrane inflamed, of a plum colour, but no sign of ulceration, abscess of its walls, or sacculi; the ureters very little dilated, and the kidneys somewhat enlarged, but not otherwise unhealthy. The stone itself was of great size, larger than the closed fist; it was irregularly oval, and evidently moulded to the shape of the bladder, the anterior and narrower end corresponding to the neck of the bladder, and the lower surface impressed with the figure of the trigone. A rounded projection on the surface answered to a cyst in the corresponding portion of the bladder. The stone in some parts, at the time of removal, was so soft that it was thought almost impossible to remove it entire. It was of the colour of mortar, and composed of the triple phosphate and evidently some animal matter, emitted a strong ammoniacal smell, and weighed three-quarters of a pound.

"Though larger stones are recorded by Earle and others, yet a stone of this size is very rare indeed. From the close contact with the bladder in this case, the operation of lithotomy could not be attempted; nor, from the size of the stone, could either lateral or abdominal operation be performed with any hope of success. Indeed, in such cases, as in Earle's, and one recorded by Civiale, the attempts are always fatal, and a similar result must have followed any similar attempt in this case."

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B — The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

THE MEDICAL CIRCULAR.

WEDNESDAY, SEPTEMBER 19, 1860.

THE BRANDY PRACTICE.

If we were asked what cause more than any other had retarded the progress of Medical Science, we should answer, Vanity—the vanity of each man in upholding his own opinion. However small our experience may be, we believe firmly in the notions we have imbibed, no matter how, or from whom. A single successful case will often determine the judgment of a sanguine man; and his opinion will be the more obstinately fixed, inasmuch as, from lack of further experience, he has been unable to compare and weigh the results supposed to have been obtained. "That's my opinion;" "my experience is decidedly in favour of such a remedy;" "that's an excellent drug—I have seen it succeed in desperate cases, when everything else had failed,"—are decisions which the interlocutor dare not gainsay. Among a multitude of contradictory affirmations, the wise man contents himself with concluding that nothing certain is known; or, if he be more charitably disposed, that there is some element of good in all the suggestions, however apparently diverse, if we could but discreetly distil it out.

For some years there had been a growing belief in the efficacy of large libations of wine and brandy in the treatment of acute disease, until we, somewhat amazed at the bold assertions and equally bold practice which seemed to support them, challenged discussion, and liberated the minds of men from a too servile dependence upon the dogmas of authoritative professors. The open arraignment of this practice in a public journal called forth the latent dissatisfaction of many sensible and experienced men, and emboldened others to pursue inquiry into the subject with a view to a definitive settlement of the controversy.

Since the time when we opened our pages to this discussion, it cannot be denied that there has been a marked ebbing of the tide of opinion, and that even the stoutest defenders of stimulation express themselves with more wariness and qualification. Is it possible to bring the points in dispute to a satisfactory issue? Can we define the diseases, the conditions, and stages in which stimulation may be beneficial or the reverse? There ought to be no doubt that we shall, in due time, be able to achieve this certainty; otherwise Medical Science must remain a wretched jumble of contradictions — no science, indeed, but a repertory of guesses, a puzzle-box of dislocated figures and facts. This would be a disheartening prospect for the labourer in the medical vineyard. Who could put his heart into his work, if he seriously believed that a philosophical certainty in physic was an end of impossible attainment?

Probably the best mode of laying a foundation for this proposed fabric of Medical Science, is to collect several large series of facts and reduce them to percentage values. However defective statistics may be in affording a positive rule of practice in particular cases, they nevertheless present us with approximative truth, enable us to lay down general principles, and provide us with guides and landmarks in the application of our knowledge. Statistics afford us, then, the best clue for finding our way out of this complex labyrinth of medical practice.

Acting upon this thought, Dr P. Fraser has, with much labour, collated the practice of the Physicians and Surgeons of the London Hospital during a period of thirty years. The interesting articles in which the results of his researches have been published, have been reproduced in the MEDICAL CIRCULAR, and our readers have no doubt perused them with curiosity and advantage.

These statistics are not limited to the exposition of the effects of stimulation in any one form or class of diseases, but apply to disease generally; and although this indefinite mode of treating the subject necessarily leaves open the numberless practical questions that arise at the bedside, yet it nevertheless presents results of very considerable value.

With regard, then, to the use of stimulants, we find that Dr Fraser makes the following significant remarks:

"Attention should be drawn to the fact that in the year 1844 there was expended for stimulants only 821*l.*, being the *smallest* amount during a period of 22 years; and that the mortality in that year was 6 per cent., the *smallest* percentage of mortality during the said period of 22 years. We are not quite satisfied but that, if a rigid inquiry were made, the largest mortality would be found where the largest quantity of stimulants was given. It is to be observed that in the year 1851, when the number of patients—viz., 4,051—was larger than in 1857—viz., 3,935,—the mortality was nevertheless greater during the latter year, as 8 per cent. to 6·50 per cent.; although the increase of expenditure for articles of luxury, &c., during 1857, exceeded that of 1851 by the large sum of 962*l.*"

The supporters of the practice of stimulation must be somewhat surprised at these results. Should they have any doubt about their correctness, we hope that they will immediately apply themselves to overset them with an array of facts equally extensive. King's College Hospital would be a rich field in which to delve for this important purpose. Dr Fraser continues his analysis, and provides us with other facts equally striking. He says:

"From the year 1849 to 1853 inclusive, the annual average quantity of wine employed by each physician was 4,928 ounces. During the same period the annual average number of patients under the treatment of each physician was 390; the annual average mortality being 9·68 per cent.

"From the year 1854 to 1858 inclusive, the annual average quantity of wine employed by each physician was 12,803 ounces. During the same period, the annual average number of patients under the treatment of each physician was 391; the annual average mortality being 11·87 per cent.

"In the surgical wards a similar unexpected result is observed.

"From the year 1849 to 1853 inclusive, the annual average quantity of wine employed by each of the surgeons was 17,533 ounces. During the same period, the annual average number of patients under the treatment of each surgeon was 1,075; the annual average mortality being 4·48 per cent.

"From the year 1854 to 1858 inclusive, the annual average quantity of wine employed by each of the three surgeons was 38,016 ounces. During the same period the annual average number of patienta under the treatment of each surgeon was 1,036; the annual average mortality being 5·06 per cent."

We reproduce these figures, not to invite in their behalf the implicit reliance of our readers, but to show that so far as the doctrine of general stimulation has been applied to the test of fact, it has altogether failed to establish its utility. These tables show, on the whole, that the larger the amount of stimulation, the higher the mortality; a result that is calculated to awaken the astonishment of the uncompromising defenders of this dogma. It is possible that another set of tables may produce results that may counterbalance those arrived at by Dr Fraser; be it so, nevertheless it will be difficult to show that excessive stimulation is either judicious or beneficial. We have employed the phrase "excessive stimulation," because we should be loth to inculcate that a moderate stimulation in appropriate cases may not be advantageously practised, and because it is the only phrase that characterises the indiscriminate and heroic practice of Dr Todd and his immediate followers. It will now be admitted that we acted wisely in bringing this subject under the notice of the Profession; and we hope yet to see the inquiries which Dr Fraser has commenced extended to the several classes and special types of disease, by which means we may arrive at more definite and practical conclusions than the present tables afford.

LITHOTOMY AT NORWICH.—From the establishment of the Norwich Hospital, in 1772, to the end of last year, being a period of eighty-seven years and a half, 863 cases of stone in the bladder were admitted within its walls, and the calculi removed by the following methods:— Lateral operation, 803; extracted by dilatation (females), 41; lithotrity, 11; median operation, 8. Of the 803 cases, 698 resulted in recovery, and 105 terminated fatally, giving a proportion of 1 in 7·647. Of the 41 females, 39 were cured, 2 died, the proportion being 1 in 20·5. One case ended fatally after the performance of the median operation. Taking the whole number, the recoveries were 755; the deaths, 108; the proportion, 1 in 7·99. The males numbered 822; the females, 41, or 1 in 20. Of late years the average of success has been high. From June 1853, to December 1859, a period of six years and a half, 69 patients were operated on; 4 died, the rest recovered, the proportion being 1 in 17·25. If 9 lithotrities and 3 females be omitted, there remain 57 on whom the lateral and median operations were performed: and as the deaths are 4, the result is 1 in 14·25.

SUMMARY OF THE WEEK.

GENERAL SLADE, LIEUTENANT-GOVERNOR OF GUERNSEY, AND THE HOMŒOPATHS.

Strange it is, that men in high position, holding responsible offices, seem ignorant of, or are so stolid as to be inaccessible to, the influence of public opinion. One would conclude that no class of men would earlier imbibe a respect for, and be brought to acknowledge its value, than military men. Numerous instances contradict this proposition, and prove how strangely they disregard the expression of public opinion. On some occasions this insensate disregard has been manifested by men of high professional status and ability. It is still more strange that public bodies seem more amenable to the influence of public opinion than private individuals. No civil or social force is equal in its influence upon society, save the law. Even the law cannot long resist or stand in opposition to public opinion. It is a great leveller, and all succumb before it. Those who recklessly put themselves in opposition to the judgment of their fellow-citizens, soon betray the inconvenience of their position, and feel about for some succour. The help they endeavour to propitiate betrays the feebleness of their cause. Appealing to some respectable motive and incentive, they endeavour to give sanction to this conduct. Thus, a liberal and scientific Profession, through the fiat of its established and acknowledged authorities, repudiates the schism of Homœopathy. It demands a denial of this schism from candidates for their degrees, honours, and appointments. None can legally practise their Profession but by the licence and permission of these authorities. Notwithstanding this state of things, sanctioned by the law of the land and the Government of the country, a man holding high command under the Crown — representative of her Majesty as Lieutenant-Governor of Guernsey —sets it at defiance, and has the bad taste to appoint a Homœopath for his Staff-Surgeon in the Guernsey Royal Militia, of which he is Commander-in-Chief. If this was a wanton act of premeditated insult, his corps and fellow-officers would surely be degraded, if not promptly resented by the resignation of the insulted Medical Officers. If it was sheer ignorance in the Governor, still in either case no other action could ensue than what took place—namely, the resignation of their commissions. Necessarily public indignation, as is usual on such occasions, became freely expressed. To avoid the storm thus raised, the Lieutenant-Governor absents himself from his command. At a public dinner given on his return by the Staff-Officers of his Regiment, amongst other platitudes he says: "Be assured that no cabal, however crafty—no clamour, however loud—and no press, however powerful, will cause me to swerve from the strict line which my *conscience* points out to me to be the correct one." Now we know that when a man talks about his conscience, he is generally in a bad way, for "conscience does make cowards of us all." It is, at any rate, quite evident that General Slade is of the sort of over-"conscientious" who "will strain at a gnat and swallow a camel."

General Slade had better make peace with his Medical Officers, for surely they will no more submit to insult than himself.

"Man! proud man,
(Drest in a little brief authority;
Most ignorant of what he's most assur'd,
His glassy essence,) like an angry ape,
Plays such fantastic tricks before high heaven
As make the angels weep."

PROFESSORS AND PUPILS.

An interesting period is on the eve of commencement, for both Professor and Student. The Medical neophyte, entering upon professional enterprise, has a misty, yet hopeful and sanguine, prospect before him. Having hitherto realised nothing in the domain of science or art, the ideal presents itself to his imagination for his hopes and fancy to play upon. He adopts his Profession upon some principle of choice. Some near relative may have followed the Profession—father, brother, or uncle. He hears from all quarters that the Profession is a hard-worked one. He embarks in it, therefore, with that stern reality before him. If a man be determined to work, he will conquer the difficulties he undertakes. The Student sees his seniors of a year have made a substantial advance. To his work he engages—he must have it always in hand. There will be no time for pleasure, so called; it must be in his work he finds his pleasure. The Professor's task, on the other hand, is an exceedingly responsible one. His hopes, in a certain measure, have already become realised in the position he has attained. No doubt he is an ambitious man, or he would not have embarked in his anxious career. If he be also conscientious, his fears commenced with his duties, and will not diminish as he proceeds. He may entertain fears of doing too little, or attempting too much. He had better be assailed by the latter than the former; he had better do little, if it be done well, than much loosely and unsatisfactorily performed. The fears of a brave and conscientious man are like discretion, which constitutes the highest attribute of valour. He fears he may come short, and aims to conquer. This man will conquer, by making every step safe as he proceeds, and victory crowns his journey. The snares which beset his path are the tendency of the day to unceasing novelty. If we thoroughly comprehended the knowledge we already possess, Pathology would not be the mystery it is. To follow out too many things without understanding the mutual relations of all, is like a child picking up pebbles upon the seabeach. The type of disease is constituted of a great whole, its prototype being health. The elements or constituents of life, health, and disease, picked up separately convey no meaning. These added together, their relations and constituents understood, convey definite knowledge, by which truth may become established. This is urged, not to discourage, but to recommend that the fruits of inquiry should be condensed and amalgamated.

LONDON HOSPITALS.

There no doubt is experienced some hesitation and difficulty in deciding upon the Hospital to be chosen for study; each, in his search and inquiries, being governed by some peculiar circumstances of attachment to individual Professors, or by convenience of locality. It is certain that the atmosphere, if we may so speak, of each Hospital is different; some bland and soft—others keen, sharp, and severe. This circumstance, no doubt, may be more or less attributed to adventitious or accidental concomitants, constituting elements either of the men who form the Medical and Surgical Staff, *genius loci*, or the condition of prosperity or want of prosperity, encouragement or discouragement, with which the Charity may be favoured. We may remark in passing, that it is a cheering circumstance to see men labour with alacrity, zeal, perseverance, and success under untoward auspices, who examine not too nicely or scrupulously the conditions by which they are surrounded, the tools they are required to work with, but earnestly set to work to finish a good labour in a workmanlike manner. If our opportunities of observation justified the attempt, it would be an invidious task to make comparisons of the merits of the different centres consecrated to carry out the behests of humanity. All are inspired with the same ardent desire that the funds of charity shall give a return of the highest interest and best recompense to the donors by the largest relief of disease and mutilation. Guy's Hospital is a noble institution, of which its officers, reciprocating the estimation in which it is held by the public, earnestly labour to justify and confirm that high approval. Utilitarianism rules and inspires the labours of the Staff of Guy's Hospital. Pedantry has no footing to be traced through its extensive wards; action and a quiet air of business pervade. Each individual looks beyond himself, entirely occupied by what is going on, and exclusiveness is a thing unknown; the work in the Surgical departments being always well and satisfactorily done under such leaders as Hilton, Cock, and Birkett. The magnitude of the establishment, and on operation days so much on hand, prevent, perhaps, so good an *ensemble* being practical as might be desired. Of St Bartholomew's, having ourselves been one of its Alumni, it may become us only to observe they retain that *savoir faire* for which they have been so long distinguished in an unbroken

line, until now, from the time of Pott. The Nestors of Surgery have fondly dwelt within its munificently-endowed cloisters—perhaps too fondly. The vitality of St Thomas's is as much sustained by its traditions as by its magnificent charities. As of old, St George's consistently retains the aristocratic *prestige* which its neighbourhood no doubt inspires. It possesses eminent Operative Surgeons: we need not remind our readers of Tatum, Johnson, and Hewett. University College Hospital is aspiring—ambitious and utilitarian: the names of Quain and Erichsen in the Surgical department guarantee its success and celebrity. But we are travelling into a region too interesting to follow—time and space are beguiled, and we must pause. We must not pass King's College Hospital. The Surgical Chief of this Institution having conquered the world of Surgery, stands conspicuously an object of admiration. A uniform scale of merit inspires and pervades the whole Staff. Let the juniors avoid a pedantic and *doctrinaire* tendency, opposite to that of their leader. The reflection which his distinguished position confers upon them, should induce them to refract and utilize the rays thus received. The spirit of enterprise which characterises them will not be less cultivated or adorned by such policy. London contains no better or more skilful Surgeon than Mr Curling of the London Hospital.

SKETCHES OF EMINENT PHYSICIANS AND SURGEONS

OF THE LAST CENTURY.

By JOSHUA BURGESS, M.D.

MEMOIR OF JOHN HUNTER, F.R.S.

(Continued from page 180.)

We can only afford space to take a rapid review of the various experiments and inquiries in natural history which occupied John Hunter during the remainder of his life, and which laid the foundation of the science of Palæontology, which is at present pursued with so much ardour and success by the Owens and Darwins of the present day, as it had been by those of the last generation.

In 1773, he read a paper to the Royal Society giving an account of the electrical organs of the torpedo; and two years after, of the fresh-water electrical fish, the gymnotus electricus, which he was the first to dissect. He discovered the electrical organs to be seated in large muscles running parallel to the length of the fish. Every farthing he could spare was devoted to these objects. Everard Home states that as soon as he scraped together ten guineas, he always made by purchase some addition to the collection in his museum. Mr Nicoll, the bookseller, father to the present or late Mr Nicoll, of Pallmall, with whom Hunter was on the most intimate terms, was an old Scotch friend, and had married Cruickshank's sister. This gentleman had had four children, three of whom died, and the survivor and youngest was undergoing the same process of hardening, by inuring to cold and sparse clothing, which the father considered necessary to make them of robust health and vigorous constitution. Hunter calling upon him one day, addressed him—"Do you mean to kill this boy also?" Mr Nicoll inquired what he meant? John Hunter then gave himself considerable pains to make Mr Nicoll understand the necessity of sustaining a certain degree of caloric in the rearing and nursing of young animals, and explained to him the process of incubation, and the application of the principle to sustain the growth, development, and health of young animals, by regulation of temperature and sustaining caloric. On another occasion, meeting Mr Nicoll, he addressed him in the following abrupt manner:—"Pray, George, have you got any money in your pocket?" "Yes." "Have you got five guineas? Because if you have, and will lend it to me, you shall go halves." "Halves! in what?" inquired his friend. "Why, halves in a magnificent tiger, which is now dying in Castle street." Mr Nicoll lent the money, and Hunter got the tiger.

The formal and fashionable Dr Garthshore—powdered, puffed, polite and well dressed, a favourite among dowagers—often dropped in to consult Hunter, and frequently would address him—"My d-e-a-r John Hunter;" on which occasions, John Hunter treated him with very little ceremony, and would reply—"My dear Tom Fool!" To raise money, he gave private lectures on anatomy and operative surgery. Although these lectures were attended by some who became afterwards the most celebrated men of their time, the number of the class never amounted to twenty at each course.

His circumstances were now so much improved, that he was enabled to engage a clever and promising young artist, Mr Bell, to live in his house, as a draughtsman, to assist in making anatomical preparations. Mr Bell thoroughly entered into the spirit of John Hunter—completed a large collection of delicate and curious preparations, and enriched the museum with a collection of artistic and spirited drawings. This gentleman obtained, through the interest of Sir Joseph Banks, an appointment as Assistant-Surgeon in the East India Company's Service. He thus improved his position in life—became a skilful anatomist, and good practical surgeon. He died in 1792, from fever, in the island of Sumatra. He sent home valuable contributions to natural history, and rare specimens of animals and corals, and contributed two papers to the 'Transactions of the Royal Society.'

In the autumn of this year (1776) John Hunter had a severe attack of illness, for which he went to Bath. This attack of disease awoke him to a serious consideration of the state of his affairs. He had hitherto expended all his earnings upon his museum. Arrived at fifty years of age, he had made no provision in case of death for his wife and family, and had always lived beyond his income. To make the collections in his museum valuable in the event of death, he saw the necessity of an arrangement of its contents, with a catalogue of the various specimens and preparations. Everard Home, during his absence at Bath, had commenced a description of the preparations; but Home, who had been six years in his house, was obliged to look out for some mode of livelihood, which resulted in an appointment in the army. Thus Hunter's labours became more severe. His personal and domestic expenses were not excessive, his family being small, and free from extravagance. When a few years afterwards he purchased the leasehold of the house in Leicester square, he mortgaged it before he could pay for it. For a long time his fees were absorbed in payment of bricklayers and carpenters, and which went but a very small way in the furnishing even a portion of this building.

In 1778, John Hunter received the appointment of Surgeon Extraordinary to his Majesty. About this time, Dr Cogan, with the aid of Dr Hawes, established the Royal Humane Society, Dr Hawes obtaining for it Royal patronage. The idea was introduced from Holland. John Hunter took an interest in its promotion, and read a paper to the Royal Society—"Proposals for the Recovery of Persons apparently Drowned." In this year he completed the second part of his treatise on the 'Human Teeth,' which he published; and also his treatise on the 'Venereal Disease.' He also in this year communicated a paper to the 'Philosophical Transactions,' on the 'Heat of Animals and Vegetables.'

About this time commenced a correspondence between John Hunter and Dr Jenner, who was practising as a surgeon at Berkeley in Gloucestershire. This correspondence extended over a period of several years, and is throughout highly characteristic of the blunt, matter-of-fact forager levying contributions far and wide. In this instance he displayed his usual discrimination and judgment, anxious to solve certain problems in natural history connected with the habits of various animals, especially of hybernating animals and reptiles, the temperature of plants and vegetables. These letters have been preserved, and are given fully in Barron's 'Life of Dr Jenner.' Jenner's letters in reply are not in existence. It would seem that Hunter's engagements were of that hurried nature, that he sacrificed everything not essential to the objects he had in view. If we may use the expression, he gave the *cue* to Jenner, knowing the man; he aimed to inspire him with the same pursuits and ideas. Jenner, like Hunter, was a naturalist.

Amongst several schemes John Hunter proposed to Jenner, was a plan to establish a School of Natural History, in which they might both be employed. He had made similar proposals to others: Jenner declined this offer. In those days, comparative anatomy and natural history were in their infancy; and in addition to the difficulty of the undertaking, such an exclusive class must have been very limited in numbers. A pupil of Hunter's, and on intimate terms with him as a friend, one morning at breakfast mentioned, in a casual manner, "that he had some thought of giving a course of lectures on comparative anatomy." Hunter looked up, and drily replied, "Sir, that is a bold undertaking. I had thought myself of doing the same thing; but the difficulties and necessary qualifications were so great, I did not think myself competent to the task. But you, I dare say, may feel yourself quite equal to it." At this time, and for some years, he devoted his attention to the subject of vital or animal heat; and his letters to Jenner gave many suggestions for experiments upon different animals. Thus, he was importunate to obtain hedgehogs. In one letter he asks for a *colony* of hedgehogs—all he had were gone. He was inquisitive to learn their habits and mode of feeding. He says, "one an eagle ate, and a ferret caught the other." His inquiries included the bustard, pea-fowls, viviparous lizards, and various other animals. About this time, Sir Charles Blagden communicated to the Royal Society some details of experiments instituted by Dr Fordyce, himself, and others. These experiments were made to determine how far the living body possessed the power of maintaining its standard heat, when exposed to air, at high temperatures. This drew from Hunter a valuable paper on the heat of animals and vegetables. It contained a history of various experiments made many years before; which experiments established that living animals, in proportion to the rank they hold in the scale of creation, possess the power of retaining their heat, and of resisting external cold.

These inquiries gave origin to some wild and extravagant speculations. John Hunter entertained the possibility of freezing human beings, and of their resuscitation by thawing, after a lapse of two or three centuries. He further anticipated making a fortune by this wild and senseless proposition. Hence the active correspondence with Dr Jenner, to which we have alluded, concerning porpoises, cuckoos, and blackbirds, and their nests and modes of breeding. Bats, eels, their sexes and propagation, not then understood, and the migration of swallows, were the subjects of inquiry. He also was equally inquisitive about vegetable life, fossils, and organic remains. His inquiries about hedgehogs were to determine their temperature at spring and autumn, and how much fat they lost during hybernation. They were also made to determine if the function of digestion continued during that condition. The details, although we have not improved upon them, are amusing in the present day, especially the minute instructions he sent to Jenner on making him a present of a thermometer, directing the mode in which he should use the instrument. His mind, stored with a large volume of nature, had a restless acquisitiveness, which could only be satiated by possession of her objects. He adopted few propositions as settled or granted. From limited book knowledge, and reading this was perhaps a necessity. He loved liberty of thought and mental freedom; no authority influenced him, until sanctioned by experiment

and his own judgment. Thus self-reliant, his progress was genial, and his anatomical demonstrations unassailable. But these triumphs would have proved barren without an ordeal to test their merit and determine their truth. When called upon to unfold the nature of his inquiries, he became foiled. He discovered that the memorial of thought, if engraved upon enduring tablets, obtained its expression through language, written or oral. John Hunter had by his labours rendered this a more difficult task, inasmuch as he had widely extended the field of discovery in science, in which language had ever been defective. In William Hunter, John fortunately found the accomplishments and learning of which he was deficient. Many of his discoveries must have remained in obscurity from incapability to express them, or to do them justice through the medium of language. It is stated, that in conversation his language was not only strictly grammatical, but his words always well chosen. It is supposed that his early intercourse with his brother conduced to this colloquial correctness. Dr Adams says,—"His last work, which was not all printed off at his death, was, I believe, entirely his own. It abounds with typographical errors throughout. . . . . It is generally supposed that his short preface was revised by Sir George Baker." (*a*).

In 1779, he published an account of the Free Martin in the 'Philosophical Transactions.' This animal was an hermaphrodite black cattle. It elicited from him an important paper upon hermaphrodism in general, accompanied with plates, and a description of its sexual organs. His avidity to obtain preparations to place in his museum from his friends made him a great beggar. The late Dr Clarke had a preparation of an *extra-uterine fœtus*, detained in the Fallopian tube. It had undergone partial development—the mother died of internal hæmorrhage, in consequence of rupture of the tube. Dr Clarke would not part with this specimen, on which John Hunter had often looked with longing eyes and set a high value. "Come, Doctor," said he, "I positively must have that preparation." "No, John Hunter," was the reply; "you positively shall not." "You will not give it me, then?" "No." "Will you sell it?" "No." "Well, then, take care I don't meet you with it in some dark lane at night; for if I do, I'll murder you to get it."

John Hunter used to say, that philosophers lie like the devil. It would seem that his brother thought they also thieved like the devil; and we must allow him to have had considerable practice in that art, especially upon John; thus fulfilling the exclamation of the Frenchman, "*Grand anatomiste, grand voleur.*" It was a more than usually barefaced act of this nature which roused John's indignation, and produced the fatal quarrel. He had shown William a curious pathological specimen obtained from the body of a Guardsman; William borrowed it of John, to show at lecture: on some future occasion, John seeing it in his museum, claimed it, and insisted on its return, which William refused.

There were singular coincidences between the opinions of John Hunter and of some of the ancient classical physicians. If he had understood the classics, he would have been, with great plausibility, charged with plagiarism. Thus he propounded opinions in public lectures which may be truly called revivals of the ancients. John Hunter would have been too proud to have availed himself of such authority, and to have proved that his thoughts were sanctioned and consecrated by the dust of antiquity. Hunter, in his lecture describing lock-jaw, says, "that if the spasm be confined to the neck, and the patient survives the fourth day, a favourable prognostic may be formed; that if it extends beyond the muscles of the neck, and the patient survives the fourteenth day, a favourable change usually commences at that time." Celsus remarks, when the spasm is confined to the neck,—"Ea sæpe intra quartum diem tollunt si hunc evaserunt, sine periculo sunt." The latter portion of John Hunter's prognosis is supported by Hippocrates. A still more singular coincidence of opinion, amounting nearly to the copy of an entire chapter of Celsus, is disclosed in John Hunter's work on Syphilis. Hunter clearly described the syphilitic ulcer, its true character being distinct from every other ulcer. Celsus, in his chapter 'De Obscenarium Partium Vitiis,' with equal faithfulness, and nearly in the same language, describes every kind of ulcer peculiar to those parts in his time. John Hunter also afterwards showed the distinction between the true syphilitic ulcer and all other sores of those parts. His being illiterate exonerated him in this instance from plagiarism. Even the learned members of the profession overlooked this ancient authority, although an almost universal controversy prevailed upon the subject. Had the pathological acumen of Celsus been known and appreciated, the scourge which has devastated society for the last five centuries might have been avoided. We have sufficient proof of his candour by the reference he has made in elucidation of this subject to every modern writer. These are not the only coincidences of John Hunter's opinions with those of Celsus. In the conclusions treating of animal heat in his 'Animal Economy,' pp. 103-4, the language of both is nearly similar. Celsus says,—"Neque enim natura sanguinis est ut calet, sed est his quæ in homine sunt, is vel calescet, vel frigescit."—Liber iv., cap. 3.

(To be continued.)

GENERAL CORRESPONDENCE.

THE MEDICAL PROFESSION, THE PRACTICE OF MEDICINE, AND THE FORTHCOMING INTRODUCTORY LECTURES.

To the Editor of the Medical Circular.

SIR,—The great recruiting time for the Profession is close at hand, when new levies are added to its ranks. From whence do they come? is a question as easily answered as asked. Not from the aristocracy, its scions and offshoots, and not from the wealthy commonalty, for these especial reasons, that there are no loaves and fishes, no sinecures; consequently, no patronage to fill snug lucrative berths for which next to nothing is done. It is recruited from the Profession itself—doctors' sons following their fathers' vocation, as certain advantages offer themselves by their so doing; lower grades of other professions sending some few of their offshoots to join the ranks; whilst successful tradesmen and agriculturists, who have worked their way in the world, and been able to give their boys a fair education, aspire to see them above their own degree and station, and are not a little proud of them as doctors. Thus we find a very varied class shouldering their way into public patronage and usefulness, the various gradations of position keeping place with the supply. Those who enter its ranks have to work hard, and to depend on their own personal exertions for living, for competency, and for fame. The largest number only get a living; by no means a large percentage ever get a competency, or are able to retire after a long life of drudgery on their own actual savings; whilst fame and competency are gained by few. As, however, a certain position in society is gained by the Medical fraternity, so is it aspired to by various grades of the middle classes. The battle, however, is not won by the strong, nor the victory by the mighty—or, rather, the most deserving do not always meet with the most success, nor are the most talented or scientific the better thought of. It does not require much learning or talent to become a thriving practitioner, and I don't know whether a limited supply of science is not the best medium to success, because it is accompanied with more assurance. Some do not care for science as long as they have a diploma to get their living; some have not the capacity, even if they tried; others have no time, even if they had both: it is the few, then, that pursue science *con amore;* so that if anything is gained by the other classes, it is on the authority of the working few. I say this, because it accounts for the few observers and thinkers we have in the Profession. Such is the paucity of knowledge possessed by the public generally of their bodies or their ailments, that they are no judges of either the science or talent of one man over the small quantum of knowledge in another. Their confidence and their estimate of worth depends on many other matters. In large communities, such as the metropolitan towns, *further advice* is always at hand; whilst in country parts people put up with what they can get, though in these districts considerable talent often exists. The man succeeds best who pursues the even tenor of his way, and satisfies the limited capacity of his patients, coinciding with their opinions, and making his treatment satisfactory to them. If they say they are bilious, the fact is admitted; if they want their bowels opened, it is done: in fact, everybody knows that a man with a tolerable address, and a little knowledge of disease and drugs, whether he have a diploma or not, yet calling himself a doctor, is as likely to do as well in town or country as the best man in the world. Such is the Profession, and which is due in a great measure to the state of the practice of Medicine—my second proposition. This is all matter of opinion, proved daily in hospital practice and teachings, in private practice, and in the records of the Medical journals. Thus disease finds its way into the wards—then comes the art of finding it out;—herein consists the charm, here the mighty magic that seizes the mind of the student. The patient and laboured investigations of the best-informed men working away in the groove of routine—the whole life of the patient, his secret microcosm, must be revealed; every symptom must be elicited, every sound within his chest recorded, every part of his body passed in review, for something must be determined on. The patient has no business there unless he can reveal some specific disease; and this being predetermined, it is safe to be found. We might ask, what is the bias of the physician? If we know that, we may, perhaps, be sure what the disease will be; for had the man gone to another hospital, it might have been something else. But there are, nevertheless, diseases and organic lesions so distinctive, that none can doubt them: yet where these do not exist and doubt does, then I say, opinion rather than actual fact obtains, which is as likely to be wrong as right. Cases are recorded, similar affections rise up in the mind; the teaching goes on. Then the treatment begins, wherein no reason or philosophy finds a place. Here fancy and predilection for some favourite drug or remedy is fully gratified. The learned physician has seen the greatest success attend the administration of such and such things, acting sometimes like a charm, reducing a train of symptoms, indicating immense mischief, into comparative safety, and it is wonderful it is not better understood. Singular enough, in other hands, under apparently similar circumstances, it never succeeds; whilst other *savans* have seen the very opposites succeed to a miracle. Very strange this! but we find the same in private practice. Whatever the crotchets or peculiar mode of practice in the teacher, the pupil becomes indoctrinated with them, and carries them—that is, as much as he can remember—into future practice; though, by the way, it is very well known that directly he pockets his diploma, so great is the latitude of the art of physicking, that he soon has his own private opinion, and physics accordingly. This is seen by the cases sent to the journals from all parts of the country; cases well drawn up—the sufferings, symptoms, and appearances all recorded, and the treatment attached. There are not two men who would have treated these alike; there is not a single man who reads them can say whether the treatment was right or wrong, on philosophical principles or laws of life. The patient recovers in one case, no one can tell how; or dies in another, no one can tell why. We seem in all this to live *in nubibus*—to be gratified more by the wonders of complexity, peculiarities, rarity, and extraordinary freaks of Nature in the metamorphoses of elementary matter, and deposit of this within certain organs, and so affecting the human body with disease, than in the elucidation of first principles of the laws which govern them, or by wise and simple rules to correct them. That a correct treatment cures, is no more explained than is an incorrect one, in ending the other way; whilst often an incorrect treatment will cure by simply altering the elements of living masses, as accidentally to assist Nature more by hit, than wit. But this is one of the most dangerous accidents, because it is the very fact that leads to a record of the treatment of the case which others follow, if not with a fatal, at least with opposite results. Who shall say, then, that Medicine is not an occult art? Now, let us for one moment, in this *getting* enlightened age, see how all this acts on the public. Our Nestors and Achilles of the Profession drive the public into the arms of charlatans. Hydropathy and other quackeries pick the pockets, whilst Homœopathy commits open burglary on the

houses, of the Profession. Yet this great combined Troy of Humbug may be truly said to "stand on our weakness, not her own strength."

As I have but limited space, I will conclude my third proposition on the forthcoming Introductory Lectures. What are they likely to be? Will they contain anything new? Will genius flash her sparks of fire; or will dull routine, couched in most carefully-written phrases, delivered in soft platitudes with the utmost decorum of enunciation and refined taste, preside? If it falls to the lot of the Surgeon, he will of course be eloquent on laying the foundation in anatomy and physiology; if to the Chemist, he will speak of these also, and urge the study of his particular science, showing what it has done, how it is advancing, and what mighty principles it has already developed, and will continue to do; if to the pure Physician, he will touch on both subjects, but cite the careful and attentive study of disease, the investigation of all that bears upon it, the induction of facts, and follow them to their pathological termination, where physic no more avails. Every Lecture will be in the language and thoughts peculiar to him who delivers it; but will they differ from what we have seen recorded every year for the last quarter of a century? Will routine be overstepped? Will any man amongst them bring forth anything new? Will any declare the practice of Medicine at a standstill, with doubt and uncertainty surrounding it? Will any deplore the want of first rudiments in the administration of remedies; the chemico-vital causes of health itself unknown, whilst its effects are alone considered? Yet there must be a point from which disease should start on its destructive course, regulated by some laws of consecutive action that have hitherto escaped observation. Will any show the progressive development of functional disturbances of secretions and organs, to the highest condition short of inflammatory actions and fevers, and reduce these again by some laws of progress and retrogression to a condition of health? Will any be so bold as to suggest reasons why some systems are more open to receive aërial poisons or atmospheric miasmata in preference to others, or any theory more extended than what is called the disposition—a term that covers an immense amount of undiscovered matter? Will any be found to give a chemico-vital philosophy why a morbid condition of the secretions should produce in one system measles, in another scarlet fever, in a third an organic lesion? Will any dare to amend the cumbrous nosology of Cullen, and propound some simple doctrine on all those disorders which might come under one head that are not of an inflammatory type, classing those which are of this character into some simple form? Will any be found who, in their course of teaching, will correct the nomenclature of the Profession, which none at present can perfectly understand, as terms for adverse actions are often mutually used? Will any point out those classes of disease which are distinctly characteristic of arterial, venous and capillary derangement, or those which are due purely to the digestive, the appropriative and hæcal departments? Will any call attention to the great fact of adverse opinions given in our Courts of Law in forensic cases, which draw down such opprobrium on the whole Profession, that makes one shudder at seeing a host of medical witnesses, and glad to escape the gibes of the public at no two agreeing? Will any simplify the use of drugs, and so divide them into classes most efficacious in those disorders short of inflammatory actions and fevers, and those which alone have influence on these latter, and others which have mechanical actions alone? Will any, in fact, give the world the charm of some novelty, and some hope of Medicine moving out of its present groove; and will any man, with his subject vividly impressed upon his mind, give a startling extempore discourse that shall make the flesh of his hearers quiver? I fear we have no such Brutuses or Antonys, "to make the stones of Rome to rise and mutiny." Would that we had! if it was only to mutiny against the dull, tame order of things which every one hugs and worships, but which is a mere dead body continually dressed in fresh cerements. Considering the amount of thought brought to bear on the treatment of disease by so many hospital professors, it may appear extraordinary that the largest experience in the widest fields produces no greater results. It cannot be, then, from the magnitude of the field worked in, that the most originality springs. Observation in a far smaller area often produces far greater results. Professors without genius are only teachers of already-admitted dogmas,—the personification of what is known, rather than leaders of new trains of thought. They, therefore, more frequently obstruct than advance; fix, more than progress: nor does it follow that when they alter, they improve, for minds once enslaved become for ever prejudiced.

Alas! then, Sir, I fear you will have nothing to record; the excitement of the first meeting of the Sessions may urge the students to request the Lecturer to publish his "elegant discourse," on which, with "soft, reluctant, amorous delay," he will request time to consider. That all the Lectures will be in accordance with established facts, theories, doctrines, and routine, there is no doubt—no more than that we may say with Solomon, after hearing them, "There is nothing new under the sun,"—though it is quite time there was in the Practice of Medicine.

HOSPITAL REPORTS.

GUY'S HOSPITAL.

(Sept. 4th.)—Lithotomy, Lateral Operation—Amputation of Foot (Pirogoff's Operation). (Sept. 11th.)—Amputation of Leg.—Mr Bryant. Amputation of Thigh—Amputation of Hand.—Mr Cock.

In our last number we had occasion to notice the frequency of lithotomy cases for operation occurring in this hospital. On this day three lateral operations were performed upon boys from eight to thirteen years of age, and seven cases of lithotomy have been operated upon within the last fortnight. In the case operated upon to-day by Mr Cock, the patient a boy about ten years of age, the stone was found so soft, it broke under the forceps during extraction; the bladder required, consequently, to be syringed for removal of the bits of stone; the stone was phosphate of lime. In the case operated upon by Mr Poland, the stone was of medium size, of phosphatic shell and lithic acid nucleus. In the third operation, by Mr Forster, on a boy about ten years of age, the stone was a lithate, with a thin phosphatic skin—so thin that it easily rubbed off—about the size of a large elongated almond.

Pirogoff's Operation.

The patient, a man about twenty-seven years of age, had suffered from disease of ankle-joint, including the bones of tarsus, and extremities of tibia and fibula, for more than twelve months. He had been admitted in hospital and discharged for change of air to Margate, and readmitted about five weeks since. Mr Bryant said it was a subject for consideration which operation was best to be done. The choice lay between Syme's and Pirogoff's operation. The patient had lately become very irritable, and his constitution was evidently giving way from suffering. The objections to Syme's operation were, that the expanded ends of the extremities of tibia and fibula between the malleoli offered a base too broad, to cover which with an artificial foot would require it to be much wider than natural, and it would not, consequently, correspond with the other foot, but be considerably wider at the heel. He said, in this case there was one objection to Pirogoff's operation. From the long-continued confinement in a horizontal position, the matter found amongst the tissues had gravitated upwards under the integuments, and thus rendered them boggy. In consequence, some sloughing might occur in the process of union of soft parts, which was no uncommon occurrence, and he decided to perform Pirogoff's operation. Mr Bryant carried a lunated incision from external malleolus of the left foot to the internal malleolus. He then carried a semicircular section over the dorsum of foot and ankle-joint. After dividing tendons and ligaments, he carried the saw through the os calcis, from below upwards, without disarticulating the ankle-joint, taking care to avoid the artery. Three vessels were required to be secured. The flap containing os calcis was then brought forward, and it was found necessary to saw off a small portion. The flap was secured with strong pins, wound round with silk ligatures, as for hare-lip. Thus, by having firm hold of flap containing the portion of os calcis, any spasmodic action of gastrocnemius muscle might be counteracted.

(Sept. 11th.)—Amputation of Leg.

This was a case very similar to one we recorded recently, and equally curious. The patient, a young man about twenty years of age, had been afflicted with partial paralysis of right leg from the effects of a fit which occurred a few months after birth. The development and growth of limb were stopped, it being full ten inches shorter than the other leg. Sensibility of the leg to touch remained; there was not *anæsthesia* of the limb. There was great diminution of circulation below the knee. The surface was cold and discoloured, being of a deep purple hue. The foot was greatly deformed—*equino-varus;* a very common circumstance in such conditions of limb. Good motion existed at hip and knee joints. Mr Bryant performed the double-flap operation at upper third of leg.

Amputation, Lower Third of Thigh.

This patient, a woman twenty-two years of age, had anchylosis of hip and knee joints, and malignant ulcers on ankle and foot. Mr Cock decided that amputation would offer some facility for locomotion with help of artificial leg, whereas she now possessed no power of motion. It would necessarily be a semi-rotatory motion from the pelvis. Mr Cock performed the double flap-operation.

Amputation of Hand, Lower Third of Arm.

This patient, a washerwoman, fifty-nine years of age, had diseased hand from a poisoned wound. The accident occurred six weeks since, and indicated great degeneration of soft and hard parts, *theca* of tendons and ligaments destroyed. Mr Cock considered the hand worse than useless; it presented an enlarged deformed mass, in appearance strongly resembling elephantiasis. An artificial hand, supposing the disease could be cured, which was improbable, would be decidedly preferable, as the anchylosed metacarpal bones extended in straight lines would be always in the way. Removed at lower third of forearm.

KING'S COLLEGE HOSPITAL.—(Sept. 8th.)

Sinus in Urethra, at Anterior Aspect of the Scrotum.—Mr Lee.

A fine young man, about eighteen years of age, received fifteen months since severe injuries, with fracture of pelvis. He had an abscess formed, which discharged internally. Another abscess formed on anterior part of scrotum, which communicated by sinus with the urethra. All the urine consequently passed by this sinus, and the semen also. There was no chance of healing the sinus while a drop of urine could remain or lodge in this opening. Mr Lee decided to make a fresh opening into urethra, about half an inch below and posterior to the sinus; then to pare with tenotomy knife and scissors the callous edges of the sinus with the object of producing a healthy process between pared edges. These several operations Mr Lee performed. After performing the first, he introduced an elastic catheter, to remain in the new opening beneath the sinus, thus preventing any urine passing during the process of healing through opening where the sinus had previously existed, or beyond the new opening. The new opening made to effect this object would heal freely after cure of the anterior sinus, it being a recent incision. In bringing edges together, after paring them, Mr Lee used metallic sutures, and instead of carrying them horizontally from side to side, introduced them longitudinally. This plan was necessary, as in erection the ligatures would, if placed horizontally, be torn out; whereas longitudinally, from the free edge of the prepuce, dilatation would be obtained sufficient to prevent this accident. Chloroform was not administered.

UNIVERSITY COLLEGE HOSPITAL.

(Sept. 3rd.)—Inguinal Hernia (Wutzer's Operation)—Sinuous Ulcer of Rectum, with Hæmorrhoids—Phymosis. (Sept. 10th.) Amputation of Breast.—Mr Thompson.

Wutzer's operation of invagination of scrotum was performed by Mr Thompson on the right side, in the usual way, on the 3rd instant, and was progressing favourably at this date; the patient, a man about twenty-five years of age.

Sinus of Rectum, with Hæmorrhoids.

The patient, a female twenty-five years of age, had a fissure of rectum externally, forming a

jagged ulcer, exceedingly painful from fæcal matter always lodging in it. Mr Thompson divided the ulcer freely with bistoury, guided by forefinger of left hand. This done, discovered a group of internal piles, which Mr Thompson secured with silk ligature. They were brought externally with forceps and tied.

PHYMOSIS.

This patient, a youth about sixteen years of age, suffered much derangement from seminal discharge, in consequence of irritation of the mucous membrane at the extremity of penis. Mr Thompson included end of prepuce between nippers, and amputated its extremity under influence of chloroform. Carried an incision of it longitudinally over dorsum of penis beyond the glans. He then removed the lateral flaps thus made by circumcision, leaving the glans and anterior penis completely denuded of mucous membrane.

(SEPT. 10TH.)—AMPUTATION OF BREAST.

The patient, a female of about forty years of age, was operated upon under chloroform. The breast showed a discoloured, malignant-looking modulated tumour, which had existed sixteen years. Slow in its early development, it latterly progressed more rapidly. The tumour was situated on the anterior and superior aspect, including nipple, of left breast. Mr Thompson said that his first impression remained, that this tumour was not immediately malignant. Its characteristics were so far favourable, that no lymphatic glands in the neighbourhood of clavicle or in axilla were enlarged, or lymphatic vessels inflamed. He amputated by a circular or oval incision—vessels required to be secured as operation proceeded. The tumour was removed very clean—there were no adhesions. It was detached easily from pectoral muscle by handle of knife. Upon cutting into the tumour, *colloid loculi* were distinctly seen dispersed over it here and there. They contained the characteristic gelatinous, slimy, glairy fluid. We understood Mr Thompson to say, that he considered *colloid* tumour not cancerous, although so considered generally; and that this patient might be exempt from relapse, and enjoy length of life, notwithstanding this disease. He was not quite satisfied of the true nature of the tumour. It certainly showed some indications which might lead to mischief. But its development having been so slow—sixteen years—glands and lymphatics not tainted, and no detachments or surrounding adhesions, were favourable circumstances.

ST GEORGE'S HOSPITAL.—(SEPTEMBER 13TH.)

AMPUTATION OF LEG.—MR TATUM.

This was an interesting and curious case. The patient, a man about fifty years of age, lost the metatarsal bones many years since from disease, which extended, and included the tarsal bones, and the whole foot and ankle. The disease assumed a malignant form. He had for many years entirely lost the use of his leg. It was a very unpromising case to operate upon; but the patient was gradually sinking, from irritation produced by the existing mischief. Mr Tatum considered a chance still remained to save life by removal of limb, if done beyond the limit of diseased tissues. He had seen it successful when another bone than the seat of disease was chosen for the seat of operation; although, from the worn-down condition of the patient's health, the chance was small. He performed the circular section, under chloroform, at upper third of leg. In cutting through, the tissues were found dense and almost cartilaginous. The muscles, upon dividing them, showed fatty degeneration throughout. The periosteum was also found very much thickened, and hard and swollen. A gland in the groin was enlarged, which was the gland receiving the lymphatics of the foot. Mr Tatum said it might not be so enlarged from the malignant disease, but enlarged from irritation set up. The same might be the case of the periosteum. No use had been made of the leg for many years. Muscles assuming fatty degeneration is explainable from innutrition. Being out of use, development and growth cease, and fatty degeneration occurs. The tendon of gastrocnemius had never been used for many years. The degeneration had also extended to the vessels. They had become so brittle and rotten, that the operation was greatly prolonged, since no ligature would hold—and their security could only at length be accomplished by including them in surrounding tissues.

Mr Tatum said the amputated leg would be injected for preparation, and might be examined in the museum. To dissect it now would spoil it for preparation.

OUR NOTE BOOK.

STEADINE, A SUBSTITUTE FOR HOG'S LARD IN THE PREPARATION OF MEDICINAL OINTMENTS.

In the last number of this Journal (Art. 5,856), when describing the ointment used for quinine frictions, we reproduced the formula of a pomade recommended by Dr Sémanas, of Lyons. This preparation has been criticised in the pharmaceutic review of the 'Moniteur des Sciences Médicales.' M. Parisel observes that the dose of quinine (30 to 60 gr.) is too large for the proportion of lard (5 dr.) "This mixture," says the author, "is very difficult to effect, and very mutable; the sulphate of quinine must therefore either lie unchanged upon the skin, or remain attached to the cotton-wool. But if steadine is substituted for axunge, the preparation is easily made up, and the amount of the saline ingredient may be decreased by ¼, on account of the greater facility for absorption imparted by this excipient." Many of our readers being probably unacquainted even with the name of steadine, it may perhaps be useful to supply them with an account of this new substance, which we extract from a paper on ointments, published in the above journal (July 7th, 1860), by M. Parisel himself:

After alluding to the impropriety of adopting as an excipient, for medicines soluble in water or alcohol, hog's lard, a substance essentially incompatible with water, and very subject to deterioration from contact with the atmosphere—a substance which, far from promoting the introduction into the system of the medicinal agent, forms, on the contrary, an impervious obstacle to absorption by the obliteration of the apertures of the skin,—M. Parisel cursorily glances at the attempts at reform which have been made in this matter. Amongst others, he records those made by M. Deschamps, the head apothecary of the asylum of Charenton. For three years this gentleman has tested, with most conclusive results, the comparative action of liniments, pomades, and soaps. Two cases, relative to the external use of iodide of potassium, are analyzed, as follows, by M. Parisel:

An ointment was prepared with 2 drachms of iodide of potassium and 1 ounce of lard.

A soap containing 1 drachm only of the same medicine was compounded with 10 drachms of excipient.

"For four successive days," says M. Deschamps, "we performed a friction every night upon the epigastric region with the first pomade, and we tested the urine excreted during the night which followed its fourth application. We detected the presence of iodine in this secretion, but in much smaller quantities than when the soap had been used in the same manner. We found, moreover, that by washing the anointed part with water, a considerable amount of iodide of potassium was obtained. Indeed, the water of the fourth lotion, performed six days after the friction, contained more iodine than the urine."

A similar experiment was made with liniments prepared with iodide of potassium compounded with olive-oil and with a saponifying excipient. The former remained unchanged on the skin, producing no other effect but to grease the surface and soil the linen, whereas the latter was clearly absorbed, a fact which was peremptorily established by distinct physiological effects.

The integument absorbing very slowly, if at all, fatty substances, numerous modifications have been proposed for the preparation of those topical remedies which have always obtained popular credit.

Mindful of the oleaginous baths which formerly were prescribed with benefit in many instances, M. Jeannel, principal apothecary at the Military Hospital of Bordeaux, has again recommended their adoption, and advised the addition of an alkali, to render them more effective. M. Tripier, an army-apothecary, has replaced plasters by soaps with organic base. Various other soaps have been likewise proposed, prepared with guaiacum, iodide of potassium, croton and cod-liver oils, mercury, &c. The codex has even retained two old compounds, one of which is extensively used, Sturkey's soap and opodeldoch, or linimentum saponis.

Facts have hitherto been, without exception, favourable to the use of soluble fatty substances. In a medical and therapeutic point of view, stearates are better excipients than lard, which has been shown to interfere with the power of medicines prescribed internally, by M. Blondlot, who, in a communication we recently noticed, demonstrated that fats destroy the solubility of arsenious acid.

Now M. Parisel is also anxious to have a share in this pharmaceutical reform in the preparation of pomades, and the excipient which he proposes to the Profession is *steadine*, a denomination which is but a contraction of the word *stearadine*, resembling fat. Steadine is prepared as follows: Lard, 3½oz.; water, 3½oz.; soda deprived of its carbonic acid by lime, 15 grains.

The soda is weighed and used dry. It should be melted in about 4 drachms of water; the lard is then gradually added alternately with the remaining water. The operation of this mixture is both swift and simple: in ten minutes, four pounds of steadine may be prepared.

This new adipose substance presents the appearance of a whitish, fatty compound, inodorous, insipid, and intermediate between cerata and lard. Its consistency, soft at first, soon acquires more firmness: it is not, like axunge, liable to liquefy during warm and to harden in cold weather. It indefinitely preserves its colour and density, unless left constantly exposed to the atmosphere; a practice injurious to other pomades and fatty matters, which turn rancid from prolonged contact with the oxygen of the air.

The slight addition of the alkaline ingredient is undiscoverable from taste or from examination with test-paper, being entirely saturated by the fatty excipient. It suffices, however, to create a new fatty substance of a mixed nature, a medium between fats and bodies soluble in water. A new and solid species of glycerine is thus produced, which is to a certain extent soluble in oils and water. This double property renders it capable of being in the preparation and use of pomades as serviceable as glycerine itself for oils and liniments.

Ointments containing metallic bases, oxides, chlorides, sulphurets, iodides, salts, &c., remain unaltered; the iodide of potassium pomade preserves its whiteness, and does not lose its iodine.

For the purpose of manipulation, it will be found most convenient. Insoluble powders mix with it promptly and with great accuracy. It is more readily combined with vegetable powders than lard, a bad solvent of their active principles. Soluble salts, extracts which require previous dilution in water, can be immediately and completely associated with steadine; whereas, when hog's lard is used, the repulsion between the ingredients is so great that a very protracted and persevering manipulation is necessary before even a badly-assorted union can be effected.

"Twelve months," says M. Parisel, "have elapsed since our first experiment. All the pomades and some ointments have been prepared according to our new process, and the success, both pharmaceutic and therapeutic, has answered our most sanguine expectations. Several physicians have watched our attempts with an active interest deserving of our gratitude, and all have been struck and pleased with the results effected. We may especially mention simple mercurial ointment, in much use for the destruction of a class of parasites which are more troublesome than dangerous. Our establishment, in consequence of the close vicinity of the barracks, dispenses an unusually large quantity of this remedy, and the military surgeons who have prescribed it have unanimously acknowledged the superiority of our steadine mercurial ointment.

"In the preparation of the ung. hydrarg. two hours' trituration have proved sufficient for the complete extinction of the mercury, instead of one month, the time usually necessary for the purpose. No rancid lard or suet, which is so injurious to the skin, was used; recently-prepared steadine has always, to our great surprise, been sufficient.

"The valuable cosmetic known under the denomination of *pommade de concombres*, the preparation of which is usually very arduous, was rapidly obtained; its perfume is more pungent and its chances of rancidity less than those of the same substance sold by perfumers. The cucumber-

juice, filtered and steadined, intimately mingles with the lard. The alkali, being in infinitely small proportion (1 per cent.), this preparation is less injurious to the skin than scented soap, which contains from 8 to 12 per cent.

"Pomades with the juice of other herbs, such as house-leek, elder, hemlock, &c., are prepared with equal ease.

"With regard to therapeutics, positive effects are obtained with substances soluble in water, such as acetate of lead, alum, tartarised antimony, sulphate of zinc, arsenical salts, preparation of morphine and quinine, and many others. Phosphorus pomade keeps also better when it has been prepared with steadine than with common axunge."

Not only is this new excipient useful in a medical sense, but also with regard to economy, *i. e.*, to the cleanliness and preservation of linen. Thus, to speak of mercurial ointment only, M. Jeannel replaces with much advantage the common ung. hydrargyri by mercurial stearates, white and oily substances perfectly defined, rational and stable compounds, for which steadine would be a most appropriate excipient.

Medicinal stearates will doubtless sooner or later replace the greater number of ointments. The first in use have been prescribed by Gondret, Alibert, Dupuytren, Devergie, &c.

Quite recently, M. Ricord has introduced into therapeutics the stearate of iron. Other inventors will doubtless follow in the same track, and the future edition of the new codex will have to assign to stearates and steadine a proper place by the side of the surviving pomades compounded on the

on its destructive co
of consecutive ac
observation.

nal of Practical Medicine and

development.

CHLOROFORM IN STRANGULATED HERNIA.

In the 'American Medical Gazette' for June, Professor E. S. Cooper, of San Francisco, has an article upon the reduction of strangulated hernia by the application of collodion. He reports one case in which it succeeded after taxis failed. "A thick coating was applied all over the hernial tumour, which being permitted to dry and contract, another was put over it. After making two or three applications, and witnessing the result, the patient was left in charge of a student, who was directed to apply the collodion (an article of much greater consistency than that in general use) every ten minutes until my return. This course being continued for nearly two hours, the tumour was found soft, and reduced in size one half or more—strangulation being, in fact, removed. The small portion of the hernial sac remaining out of the abdominal cavity was returned without the least difficulty."

Prof. Cooper gives the following conclusions: "1st. That we will always be safe in resorting to the use of collodion in strangulated hernia before using the knife, which, at best, is a dangerous remedy.

"2nd. If the collodion fails, the case will be none the worse for an operation, because two hours will generally be a long enough time in which to give it a trial; and during this period no more fluids can accumulate in the tumour, but, on the other hand, part of those already collected will be sure to be forced out, whether strangulation is subdued entirely or not.

"3rd. That taxis should never be resorted to before collodion has been applied, because, in the former, bruising of the parts is liable to occur, but not in the latter, which, in addition, is much the more potent agent in pressing the blood out of the veins of the part, and thereby relieving the strangulation."—'American Medical Monthly.'

STRICTURES OF THE URETHRA.

In the 'American Medical Gazette' for June, Prof. James Bryan has an article upon the treatment of this troublesome and hitherto seldom-cured affection. For fifteen years past, Prof. Bryan has been treating strictures of the urethra by internal section; a mode of treatment which, he says, in that time, and with rather extensive experience, he has never known to fail. We must refer our readers to the original article for a description of the instrument used. He concludes his paper with the following remarks: "The more cartilaginous and impervious the stricture, the better; and I have yet to see a case in which I have failed to open a passage to the bladder. It is well known that the treatments by caustic, dilatation, and external section, are all followed, from time to time, by severe accidents, such as increase of the stricture, false passage, with urinary infiltration, fistula, &c. &c. I have, as yet, met with none of these things in this treatment; nor are any reported by Civiale, Strafford, Amussat, Dorner, Jameson, or others. *A priori* reasoning doubtless deters many from attempting the practice; but after a careful review of the results of other modes of practice, not excepting Symes' operations, I am clearly of the opinion, that in a majority of the cases of permanent stricture, the treatment by internal section, in the hands of careful and judicious surgeons, is by far the safest, most free from danger, most certain, and most satisfactory."—'American Medical Monthly.'

FŒTUS CARRIED TWENTY-TWO MONTHS BEYOND TERM.

Before the Boston Society for Medical Improvement, as per report in the 'Boston Medical and Surgical Journal' for June 14th, Dr Storer reported the case of a woman who carried the product of conception for more than two years and a half! At the full period she "was supposed to be in labour, and sent for her family physician to attend her." "The pains, however, were not constant, or of much force, and soon subsided entirely, never to return as true labour pains." Twenty-two months later she died, having carried the product of conception the while, and menstruated irregularly until the time of her death.

"At the autopsy a very extensive adhesion was found between the fundus of the uterus and the small intestines, and also between its side and the sigmoid flexure of the colon. The Fallopian tubes and ovaries were found in their natural relations to the uterus. The uterus contained a fœtus in the natural position for delivery, but no trace of a placenta could be found. There was about a pint of thick yellow fluid in the uterine cavity. An opening in the left side of the uterus communicated with the interior of the colon, and the left hand and forearm of the fœtus were passed into the bowel, as far as the elbow. Faculent matter had passed into the cavity of the womb. The os uteri was entirely closed, and no trace could be found of it upon the inside."

LIQUOR AMNII.

In the New Orleans 'Medical News and Hospital Gazette' for June, Prof. D. Warren Brickell has a very interesting and able paper on the function of the liquor amnii. He enumerates all the functions ascribed to it by obstetrical writers, fourteen in all. The first eight enumerated he considers quite visionary, and, with perhaps one exception, entirely unfounded in fact. The eight rejected, each has one or more of such names as Churchill, Rigby, Dewees, Tyler Smith, Baudelocque, Cazeaux, Ramsbotham, &c., in their support. Prof. Brickell urges his objections forcibly, and we think conclusively. The functions named by authors to which he gives his assent are the following: 1st. The liquor amnii secures the fœtus from external violence; 2nd. It protects the fœtus from the uterus; 3rd. It protects the cord and placenta from pressure during gestation and labour, and thus preserves intact the circulation of the child; 4th. It assists dilatation of the os uteri in labour; 5th. It favours the presentation of the head of the child; and 6th. It favours the development of the fœtus. The third and fifth functions he considers of the first importance, though insisted upon by only a very few obstetric writers. To the above functions Prof. Brickell adds another, thus: "I assert that an important function of the liquor amnii is to counteract the specific gravity of the fœtus, and thus prevent disagreeable physical results to the woman in the later months of pregnancy, when the weight of the child becomes considerable. At full term the well-developed fœtus weighs from six and a half to eight pounds; and from the seventh to the ninth month of pregnancy, the weight varies between four and a half to five pounds and these first-named weights." We have not the space to give the Author's argument in full, and must be content with a synopsis. "I find by actual experiment, that if a five-pound weight is placed on the back of my hand, and the palmar surface of the hand is then placed to a table—thus establishing counter-pressure—pain is soon experienced, and it is not long before that pain becomes insufferable—the degree of endurance, of course, varying in different persons, according to the degree of muscular development, &c.; and I am sure that long continuance of the pressure would cause death of the tissues immediately, under the weight." . . . "If there was no water in the womb, the weight of four and a half to eight pounds would be pressing on the womb tissue (inferiorly), with the counter-pressure of the pelvis below; and this, as we have shown, could not be borne." Now, with all due respect for the opinions of Prof. Brickell, we cannot avoid the conclusion that this function is somewhat visionary and chimerical. We have certainly seen patients in whom the liquor amnii had escaped, and yet the fœtus of near maturity was carried for days, and, in one or two rare instances, for weeks, without any expressions of discomfort from pressure, &c. We all know that females occasionally carry solid tumours, surrounded by no fluid, for years, without any of those disastrous effects upon the tissues to which Prof. Brickell alludes. To carry a weight of that of the human head upon the shoulders, would, in a few hours, become a tiresome feat; but to carry the head where nature placed it, is a different matter altogether.—'American Medical Monthly.'

THEOPHILUS THOMPSON, F.R.S., F.R.C.P.

Death has been paying us sudden and startling visitations of late. Month after month our ranks have been thinned by the unexpected fall of some of our best and ablest men; and now yet another has been added to the list, already too long. We are sure that the recent announcement of the death of Dr Theophilus Thompson was observed by none of our readers without genuine sorrow and concern. By his removal, a life of more than ordinary activity, usefulness, and scientific success has been brought to an untimely close; and not merely a large circle of private friends, but the whole Medical brotherhood, and, indeed, society at large, have sustained a loss which will be neither soon nor easily repaired.

Dr Thompson commenced his professional studies at St Bartholomew's Hospital, and subsequently continued them for two years at Edinburgh, where, after familiarising himself with the teaching and practice of the Dublin and Paris schools, he graduated with distinction in 1830. He then settled in London, and was shortly afterwards elected Physician to the Northern Dispensary. For fourteen years he continued to discharge the duties of this office with the most laborious care, conscientious precision, remarkable skill, and undeviating tenderness to the sick poor. About this time Dr Thompson took a special interest in diseases of the nervous system; and some of the fruits of his investigations were embodied in the articles "Hysteria," "Neuralgia," "Chorea," and others, contributed to the 'Library of Practical Medicine.' These articles were in advance of the time at which they were written: clearly and elegantly composed, they also carry the stamp of correct observation, close reasoning, and great practical skill. He lectured for some time, on the Practice of Medicine, at the Grosvenor-place School of Medicine, when this institution was directed by Mr Samuel Lane. Here, as elsewhere, he won the respect and affection of colleagues and pupils.

In 1847 Dr Thompson was appointed Physician to the Hospital for Consumption, then instituted in Marlborough street, prior to the erection of the present building at Brompton; and in the organisation and management of this noble institution he continued to take a prominent part almost to the close of his career. It was thus that his later inquiries became specially directed to the investigation of thoracic disease, and enabled him to make those contributions to our knowledge of pulmonary affections which gave him so high a place in professional estimation, and made his opinion at once eagerly sought for and highly valued.

Dr Thompson enjoyed at the Brompton Hospital great opportunities of investigating the pathology of pulmonary diseases, and of testing the value of remedies proposed for their treatment by himself and others. Of these opportunities he availed himself with rare diligence and discrimination, and his published papers afford good evidence of the success of his work—valuable for the errors which it refutes as for the truths which it advances and confirms. Numerous, however, as are the fruits of his labours which we have reaped, we are assured they are but few compared to those which would have sprung from his inquiries if they had been permitted to be continued.

Dr Thompson helped much to remove the mystery which for a long time obscured the art of auscultа-

tion, and published some valuable and fruitful hints on the subject, with a view to the simplification of terms and arrangement. He early drew the attention of the profession to the value of cod-liver oil in the general treatment of phthisis, and to the use of bismuth and oxide of zinc in the alleviation of some of its most distressing symptoms. In 1844 he prepared a laborious, learned, and otherwise admirable account of the successive epidemics of influenza, issued by the Sydenham Society. In 1856 appeared his Clinical Lectures on Consumption, delivered at the Brompton Hospital—a work at once eminently suggestive and practical, and indicative of the author's remarkable fertility in therapeutic resources, and of his mastery of those minor details of management which conduce sometimes more than medicine to the successful treatment of disease. In the following year he published his Lettsomian Lectures, previously delivered before the Medical Society of London. The theme again was phthisis, and in the treatment of it he revised some of his earlier opinions, and exhibited that disregard of self, that candid and genial acknowledgment of the labours of others, and that unaffected love of truth for its own sake, which so eminently distinguished him amongst his brethren.

More lately the medicinal use of ozonized oil occupied Dr Thompson's attention, and after a carefully-conducted but incomplete series of experiments, he directed the attention of the profession to the subject, in a paper published in the last volume of the 'Medico-Chirurgical Transactions.' His last paper was on the Changes of the Blood produced by the Administration of different Oils. It was read before the Royal Society, and was justly considered to be a contribution of great value.

These, however, were but a few of the scientific subjects which engaged Dr Thompson's thoughts. Much he proposed, which, if he had lived, he would have executed. One design only we shall mention, because its object would supply a peculiar desideratum. He contemplated the production of a systematic work on the Practice of Medicine, which was to have been based on the records of typical cases, and confined, in its treatment of general theories, within the strictest limits which a rigid induction from them would justify. This was an original and great idea; and it is to be hoped that his son, who has already given evidence of his father's talents and virtues, will not allow the materials collected for its realization to be lost.

As early as 1855, slight indications were observable of that progressive muscular atrophy which, in 1859, compelled Dr Thompson to withdraw from the active duties of his profession, and, at a later period, terminated his life. In 1857 and 1858, he derived some benefit from the use of the Buxton waters. In 1859, he spent some weeks, under the care of Dr Wetzlar, at Aix-la-Chapelle, but without any lasting improvement. The progressive failure of muscular power, and other symptoms associated with it, suggested to the minds of the medical friends in attendance upon him the existence of softening of certain parts of the spinal cord; but he himself said this hypothesis was not needed to account for his symptoms, and was inadequate to explain them. At first the muscles of animal life were alone engaged; by-and-bye those of respiration became involved; and in this condition he was attaked with bronchitis. Declension was now rapid. The bronchi became loaded with mucus, which could not be expelled; and though the intellect remained strong and unclouded, the physical power succumbed, and he entered into his rest on the 11th of August, in the fifty-third year of his age.

Dr Thompson was a regular attendant at the Medical and Royal Medical and Chirurgical Societies. Many of his papers were read before them, and were recorded at the time in the pages of the 'Lancet.' In debate he was clear, argumentative, and suggestive. He was thoroughly independent. He was the constant friend of free discussion and a free press. When a base conspiracy was formed against this journal, and when that conspiracy developed itself at one of the annual meetings of the medical and Chirurgical Society, Dr. Thompson placed himself foremost amongst the defenders of the 'Lancet.' This was an act so characteristic of the man, and so honourable to his memory, that we cannot pass it by. In a few energetic, noble, and convincing sentences, he demolished the sophistry and the malignity of our opponents. This was the more to his credit as he was totally unconnected with us, except as an occasional contributor. This tribute to the only independent medical journal which existed was spontaneous and disinterested. It failed, indeed, to convince the majority of a packed meeting of their cowardly and contemptible conduct; but out of the meeting-room his speech produced a result which, whilst it placed him in a position of the highest honour, covered the conspirators with irretrievable disgrace. We have no cause to regret the results of that memorable onslaught on our credit and independence. The 'Lancet' flourishes: where are the conspirators?

Our limits must content us with this imperfect sketch of Dr. Thompson's medical career. In questions of treatment, and in the scientific inquiries of medicine, his opinion was esteemed by his professional brethren amongst the very first. That he did not rise to quite a corresponding notability with the general public, may be attributed, perhaps, to a slight excess of scientific caution and social reticence, which refused to bow to the popular taste for a certain dogmatism and pretentious positiveness. Dr Thompson's intellectual habits were carefully formed, and his discriminating taste in literature and composition told most favourably on his own style as a writer. Amongst the most pleasing characteristics of his mind were a genial fancy, a playful humour, a fluent elegance of speech, and a remarkable facility for illustrating the chance subjects of conversation by the resources of a richly-stored and highly-cultivated mind. An almost chivalrous devotion to truth was a leading feature, not only of his scientific enterprises, but of all the thoughts and occupations of his life. In the cheerful equanimity of his course the real principle of his life was revealed, and felt, more or less, by all who came in contact with him. It was not the struggle for gain or professional notability, but the earnest and loving search for truth. He accepted with simple faith the highest truths of the spiritual world, and rejoiced in following out their harmonies throughout the realms of matter and mind. It was this which gave the chief dignity and unity to his life, and made death itself something far other than an interruption or an overthrow. We can scarcely conclude this notice better than by a quotation of his own words. At the end of his Clinical Lectures on Consumption, he characteristically wrote: 'Am I passing beyond becoming bounds in suggesting the reflection that, while witnessing such transitions from languor and decay into undying life, we may ourselves realize the truth that death is not the end of existence; that it is something grander than human skill defeated; that when art can do no more, and friends 'weep at the vestibule as the spirit passes out of doors,' we may win glimpses of brighter scenes, where the cares and passions of this lower life shall cease to engross, and the germs of opening science shall expand into the fulness of infinite truth?"—'Lancet.'

SIR R. A. CHERMSIDE, M.D.

It is with regret that we have to record the death of Sir Robert Alexander Chermside, which took place at Oxford on Saturday week. The deceased was the third son of the late Dr Chermside, of Portaferry, Co. Down, and entered the Medical Service of the Army in 1810 as Assistant-Surgeon in the 7th Hussars. He served in France, Spain, Flanders, and elsewhere, and was present at the battle of Waterloo. Immediately after that sanguinary engagement he was promoted to the Surgeoncy of the 10th Hussars. In 1821 he was admitted a Licentiate of the Royal College of Physicians, London, and in 1836 elected a Fellow of that College; he graduated as M.D. at Edinburgh, and was a member of the Royal Colleges of Surgeons of London and Edinburgh, and of the Société de Médecine Pratique of Paris. For some years previous to his death he held the post of Physician Extraordinary to her Royal Highness the Duchess of Kent, and was Physician to the British Embassy at Paris. In recognition of his war services he was created a Knight Commander of the Order of the Guelphs of Hanover, a Knight of St John of Jerusalem, a Knight of the Red Eagle of Prussia (conferred for services to the Prussian troops in the campaign of 1815), and a Knight of the Legion of Honour of France.

"Suffocation" of Children in London.—Dr Lankester, in his 'Fourth Annual Report' as Officer of Health of St James's District, calls especial attention to the increase of infant mortality from suffocation:—"There is one group of deaths which present in our parish a very extraordinary increase, and which I do not think I ought to pass over without notice. I allude to the record of deaths by suffocation. Of the fourteen cases recorded this year, eleven are of infants under one year of age. In 1856 only two such cases were recorded; in 1857 not one; in 1858 there were only four. It appears that, in general, these cases are recorded as found dead in bed with their parents. Such death is suggestive of culpable carelessness on the part of parents, or of horrible criminality. The increase of infant mortality, under the head of 'Suffocation,' is not confined to our parish, but embraces the whole metropolis. In 1858, there were 230 deaths from suffocation; and in 1859, there were 288 deaths from the same cause. As a proof that there is something more than an increasing indifference to the sanctity of human infant life, I would refer to the fact, that recently no less than eight children were found murdered in one week in various parts of London."

DEATHS.

Chase.—July 29, suddenly, at Brooklyn, New York, Edward Chase, formerly of Luton, Bedfordshire.

Chermside.—September 8, at Oxford, Sir Robert Alexander Chermside, M.D.

Johnson.—September 2, at Stockport, Cheshire, George Johnson, M.D. Univ. Edin., aged 50.

Maclaine.—September 8, at Cranham cottage, Garngad road, Glasgow, J. D. Maclaine, Lic. Fac. Phys.

Moore.—September 6, John Moore, of Keastwick, near Kirby Lonsdale, formerly of Bolton-le-Moors, aged 81.

Piercey.—September 10, at St Thomas' street, Portsmouth, Moses Piercey, M.R.C.S. Eng., L.S.A. Lond., aged 49.

Turton.—September 3, suddenly, Randle Turton, of Ablow House, Wolverhampton, M.R.C.S. Eng., L.S.A. Lond., aged 52.

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their examination in the science and practice of Medicine, and received certificates to practise, on Thursday, September 6th:—Francis James Hammond, Sherborne, Dorset; George Handcock, Cad-Busfon, Leeds; Henry Wright Lomas, Belper, Derbyshire.—The following gentlemen also on the same day passed their first examination:—Charles Henry Fowler, Charrington street, Oakley square; Joseph Harper, Great Torrington, North Devon; William Owen Jones, Bryntegid, Bala, North Wales; William George Tayler, Kilmeston, Alresford, Hants.

Appointments.—Dr Anstie has been appointed Assistant-Physician to Westminster Hospital.—At a meeting of the Committee of the Liverpool Dispensaries, held on September 6, Mr James M. Bennett was unanimously elected Hon. Surgeon to the South Dispensary, in the room of T. D. Fletcher, Esq., resigned. Mr Bennett had previously been one of the House-Surgeons to the Institution.

Testimonial to a Surgeon.—A handsome silver tankard has been presented to J. C. Garman, Esq., manufactured by Messrs Etheridge, of Norwich, and bearing the following inscription:—"Presented to John Cooper Garman, Esq., M.R.C.S.L., by upwards of 300 inhabitants of Shipdham and neighbouring parishes (the poor forming the greatest number), as a mark of respect upon his leaving Shipdham. June, 1860."

The late Smyrna Hospital.—A question of about three months' pay in connection with the late Smyrna Hospital has at length been decided in favour of the four senior Medical Officers concerned—Drs Leared, Barclay, and Gibbon, and Mr Holthouse. The case had been entrusted by his colleagues to Dr Leared, and that gentleman cordially acknowledges the disinterested kindness of Mr Brady, M.P. By his persevering efforts, this just claim was at length conceded by Mr S. Herbert, Secretary at War. This is not a solitary instance of Mr Brady's good offices in behalf of his own profession, whose fearless champion he has always proved himself.

Radcliffe Infirmary, Oxford.—We have the pleasure to report the munificent gift from his Grace the Duke of Marlborough of 164*l.* to this Institution. This sum, in addition to gifts in 1858 and 1859, has been derived from the payment of visitors to Blenheim Palace and Gardens. The amounts in 1858 and 1859 were respectively 100*l.* and 135*l.*

American Diplomas.—An American medical contemporary states that the case with which charters are now obtained from state legislatures, for every nondescript association of men, whether for proper or improper purposes, has effectually broken down all safeguards to respectability, and thrown the field of medicine widely open to every species of adventurer. Charters are granted by state legislatures to any and every body of men, for any and every conceivable purpose, without discretion or reserve. At nearly every session a batch of medical institutions are chartered, embracing every shade of quackery; and these, equally with the respectable and legitimate schools of medicine, are entitled to confer the degree of M.D., and to represent themselves abroad as universities. It is difficult to imagine

a more deplorable state of confusion than such reckless state patronage of ignorance and quackery must produce. Already it threatens to disorganise the educational system of the Profession in America; for adventurers are thus freely enabled to purchase that academical status which only education can confer in other countries. The inevitable result must be, that since we have no means of distinguishing here, amongst the multitude of American colleges, those which apply the necessary tests to their members from those which admit the most unworthy persons, American diplomas will fall into discredit, and will be regarded as one of no value.

LUNATICS IN SAVOY. — France, in annexing Savoy, assumes also charge of the lunatics, idiots, and cretins of Savoy, to whom the benefits of the enactment, under the French law, concerning the support of persons of deranged mind is extended by two new decrees. The asylum erected at Bassens, near Chambery, received by these decrees the character of a public establishment, and a hundred free places in it are reserved for the most helpless idiots and cretins of the two departments of Savoy and Upper Savoy. A subvention of 40,000 francs is granted for expenses of construction and organisation, and for payments of the debts of the public asylum for idiots at Bassens.

THERE is a talk of forming an Academy of Medical Sciences in the island of Cuba.

BEQUEST.—M. C. Berrier, a manufacturer at Liege, recently deceased, has bequeathed to the civil hospitals of the town the sum of 223,000 francs, and the reversion of his dwelling-house, on condition that the Administration of Hospitals shall pay to his widow an annuity of 10,000 francs during her lifetime.

"CHEMISTRY," says Miss Nightingale, "has as yet afforded little insight into the dieting of the sick. All that chemistry can tell us is the amount of 'carboniferous' or 'nitrogenous' elements discoverable in different dietetic articles. In the great majority of cases, the stomach of the patient is guided by other principles of selection than merely the amount of carbon or nitrogen in the diet. No doubt, in this, as in other things, Nature has very definite rules for her guidance; but these rules can only be ascertained by the most careful observation at the bedside. She there teaches that living chemistry, the chemistry of reparation, is something different from the chemistry of the laboratory."

THE use of hypophosphites in phthisis has been tried even in Spain. Don Marsillach has subjected twenty patients to its use; seven of these died, twelve were unable to continue taking it, and one only—a doubtful case—got well. The Don, therefore, agrees with M. Dechambre, Dr Quain, and others, as to the inefficacy of the remedy in phthisis.

A TIMELY HINT.—M. Lukomski, having forwarded to the Société de Chirurgie a 'Memoir on the Treatment of Syphilis by Successive Vaccinations,' M. Guérin was requested to report upon it. In concluding his report, he proposes that the author should be called upon to cease this kind of experimentation, "which is dangerous to the patient, and may at last compromise the operator."

THE 'Boston Journal' contains an account of a successful operation of gastrotomy, performed for the purpose of extracting a bar of iron from the stomach of a juggler, who had allowed it to slip down his œsophagus during the performance of one of his *tours de force*.

"I OFTEN think," says Sydenham, "that we forget the good rule *festina lente*; that we move more quickly than we ought to do; and that more could be left to Nature than we are at present in the habit of leaving to her. To imagine that she always wants the aid of Art is an error, and an unlearned error too. If it were so, she would have provided for the human race less than its preservation demands."

PROFESSOR BOYER, OF MONTREAL.—This distinguished physician, one of the Medical officers of the Hôtel-Dieu Hospital at Montreal, and Professor of Medicine and Medical Jurisprudence in the French College of Medicine in the same city, has just left England on his return to his native country, after some months' sojourn in this metropolis and the principal capitals of Europe. He has met everywhere with the respect due to his position and standing in the Profession, and his natural urbanity of manner and kindness of heart. The hospital to which the Professor is attached is the largest in Montreal, and contains several hundred beds; it was founded originally by the nuns, who perform the duties of Sisters of Charity.

"THE campaign," we read in a French journal, "undertaken for the repression of Quackery, is carried on with success. We have to register two more judgments of the Correctional Tribunal, with an indemnification for the Medical men who are plaintiffs."

THE Scientific Congress of France assembled on Sunday in the Hôtel de Ville of Cherbourg, for its annual session. The number of members of the Congress now is 560.

A PERSON signing himself "Robert Maber, Surgeon, formerly of Swansea," appears to have an honourable residence in the Agapemone. As there are men in our Profession who really believe in Homœoqnackery, Table-turning, and Clairvoyance, we need not be surprised that one should be found with an intellect fitted for the Agapemone.

M. VELPEAU says that many plans have been proposed to obtain obliteration of arteries without ligature, but almost all of them have been abandoned; in his opinion acupressure will share the same fate. In two cases in which he tried it, inflammatory symptoms necessitated the removal of the needles. Might not M. Velpeau just as well refuse to amputate a limb, because the operation is sometimes followed by accidents of this kind?

EXTRACT OF RHATANY.—When prescribed in aqueous solution, the extract of rhatany generally falls to the bottom. This may be prevented by adding to the pulverized extract a little water, and from twenty to twenty-five drops of alcohol—an addition, however, not required, when tinctures are prescribed with the extract.—'Bull. de Thérap., June, p. 538.

IN this country none of the higher posts of honour which incite the members of other Professions to intellectual efforts, neither the peerage nor the legislature, are open to Medical men. Those, too, of our brethren who are most competent to speak upon the many important topics connected with the maintenance of health, whether at home or abroad in connection with our colonies and dependencies, are not, as a rule, occupying the administrative offices for which they are peculiarly fitted; and Medical men are seldom sought out as the friends and advisers of those high in place, who could not but be advantaged by their counsel. Such a state of things must be regarded as unfavourable to the due position and prospects of Rational Medicine. "They order things better in France," whatever we may think of our neighbours in other respects. There, Medical impostors are dealt with fairly, but summarily; and the members of our Profession, in common with scientific men, are seen to occupy high stations in the State.—Dr. Ward's 'Hunterian Oration.'

AN UNUSUAL SURGICAL LESION.—M. Gosselin admitted at the Beaujon Hospital, on the 1st ultimo, a robust man, aged forty-three, who had met with a fall from a plank lying between boat and quay, just after he had made a great effort to place a sack of coals on his shoulder. On admission, no fracture or dislocation could be observed about the shoulder-joint upon which he had fallen, and where pain was complained of. Simple contusion was the diagnosis. The man was seized with delirium the same evening (probably *tremens*), and died fourteen hours after the onset of the cerebral disturbance. On the examination, no lesion was discovered, but a little blood within the capsule, and a slight crushing the spongy texture of the head of the bone. Was this the result of the fall or of the effort?

ANOMALY OF THE URETERS.

Professor Barbosa observed the following curious anomaly in a body brought to the Lisbon Anatomical School. Two distinct ureters existed on the left side, entering the bladder by two distinct orifices. The left kidney was longer by three centimetres than the right, and the two ureters at their origin in the fissure were each provided with a separate pelvis, the united capacities of which only equalled that which would be required for a kidney of this size. The two canals, separated from each other by about three centimetres at their origin, pursued the normal course one before the other. At about five centimetres from the bladder they united into a single cord which traversed its muscular tunic. Careful dissection, however, showed that this confounding together was only apparent, the two tubes being separable as far as their entrance into the bladder, at the angle of the trigone, where were two small orifices one or two millimetres from each other. During the last two centimetres of their course the contiguous walls of the two tubes were so blended together as to constitute but one.—'L'Union Méd.'

APPOINTMENTS FOR THE WEEK.

Wednesday, September 19.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, September 20.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.

London Home.—2 p.m.

Friday, September 21.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, September 22.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, September 24.

Operations at the Royal Free Hospital, 2 p.m. Metropolitan Free Hospital, 2 p.m.

Tuesday, September 25.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

CHIRURGUS.—Yes; the qualifications suffice.

MR PARKER.—Note received.

MR ADAMS.—1st. It is a reliable preparation.—2nd. Sarsaparilla is utterly useless.

A NON-REGISTERED ASSISTANT. — You ought to register.

L.R.C.P. EDIN.—1st. Yes.—2nd. Not at present.

A SUBSCRIBER.—The benzoated oxide of zinc ointment is ordered to be prepared, by Mr Wilson, by first melting the benzoin with a slow heat for twenty-four hours, then adding it to the zinc ointment. It is useful in some cases of eczema, but we have oftener known it fail.

H. L., on Antimonial Poisoning, received. The article does not, however, contain any new views or facts that would justify its publication in our pages.

DR EDWARDS is thanked.

MEDICUS (Cheltenham) will find the article he requires in the Number for Dec. 14, 1859.

R. H. B.—The higher fee is unnecessary.

DR RIDGE.—Received and inserted.

MR DE LISLE.—Received.

Letters received with enclosures.—Dr Seaton, G. Downie.

Mr Harris (who for SEVEN YEARS was Secretary, &c., to the Medical Directories) has REMOVED from Adam street, Adelphi, to 21 King William street, Charing cross, where business matters generally are promptly and faithfully transacted on moderate terms.

INSTRUMENTS, Books, or any other property, obtained or disposed of to the best advantage.

PATENTEES, and others requiring assistance, are invited to call or communicate: likewise,

MEDICAL GENTLEMEN having anything they wish introduced to the Profession or Public are invited to apply.

ADVERTISERS, and Parties wishing to Advertise, are advised and assisted.

MR HARRIS having travelled through England, can afford information, &c., respecting the different Towns; also on matters connected with Life Assurance.

INVALIDS and others requiring any information may save time, trouble, and expense, by personal or written application.

PARTICULARS of anything Advertised in the 'Medical' or other Journals afforded to Enquirers, and the articles, or any others, examined, procured, and forwarded on receipt of P.-O. order for the amount.

ALL LETTERS and replies thereto must be prepaid.

OFFICE HOURS from Two till Five, or by appointment.

ADDRESS, Mr C. J. Harris, 21 King William street, Charing cross, London,—W.C.

Pure Air is as valuable as Pure Water, and may be obtained, with perfect Ventilation, by the use of WHITE'S PATENT VENTILATOR and AIR PURIFIER, which is invaluable for Sick Rooms, Public or Private Buildings, and especially so for India. May be seen at Mr HARRIS'S, 21 King William street, Charing cross, W.C., from Two till Five.

N.B.—Medical Gentlemen are invited to inspect this Instrument.

CLINICAL LECTURES.

ON THORACENTESIS:
ITS INDICATIONS AND COUNTER-INDICATIONS IN PLEURISY.

DELIVERED AT THE HÔTEL-DIEU,

BY M. ARAN.

(Continued from page 172.)

You have seen me perform thoracentesis. The puncture was made in the seventh intercostal space, in the direction of the axilla, and gave issue to 1,900 grammes of a serous fluid, which became a gelatinous mass like the coagulum of blood abstracted by venesection. You have thus seen verified the first two points of the diagnosis; that is, that there was an abundant effusion, and that the effused fluid was the product of inflammation of the pleura. The night following the operation, the patient, who experienced no untoward symptom, slept well and felt greatly relieved. His pulse, the following day, was 96, and the respiration 24; this morning it is only 20. I need farther only say that the lungs, in consequence of the evacuation of the fluid, have regained nearly their normal volume, and so present a larger surface for the purposes of respiration. Have you not also seen that sonorousness soon became re-established throughout the whole chest, and the respiratory murmur reappear where it was some hours before completely wanting?

I am not ignorant that a good many physicians could be found who would not in this case have had recourse to the same means. They would first have employed blisters and diuretic potions, and have waited in the hope of seeing absorption take place—a method I have not followed, because I have learned from experience that in such cases you wait in vain and for too great a while. Consider, besides, the general state of the patient; and is it not apparent that that could only have become worse and worse under the influence of continued confinement to bed, and the impediment which the respiration suffered from such copious effusion? Nay, more; I shall say that the complication with tubercles, which some regard as a counter-indication of the operation, is, on the contrary, one of the reasons that led me to decide on it. In fact, I regard the effusion as a source of irritation—a sort of thorn which, by its presence, favours the development of tubercles. In my opinion, the indication is express: the fluid is to be evacuated. As regards the physicians who, on the contrary, consider the tubercular complication as counter-indicating the operation, they are chiefly guided by the following reasons:—The lungs being strongly pressed together, the walls of the caverns are maintained in contact; hence conditions the most favourable for cicatrization of the caverns. But in our patient such was not the case; for, when forming our diagnosis, the question, you are aware, was not whether the lungs were excavated by vast anfractuosities, but simply whether there were tubercles in the first stage of development. Moreover, no one has yet shown that cicatrization of the caverns ever takes place under the circumstances now mentioned. It is pretended by others that evacuating the fluid by thoracentesis favours the development of the tubercles. I acknowledge my repugnance to admit that by ridding the patient of one complication of his ailment, you only favour its farther increase. It is objected also that the fluid may be reproduced by the irritation which the tubercles exert on the pleura. But when an organic affection of the heart, of the liver or kidneys, brings on ascitis, are these objectors prevented from having recourse to abdominal paracentesis by any such considerations? Thoracentesis, practised in former ages, next lost sight of, and now lately restored, is certainly one of the finest conquests our art has achieved, and one of the most powerful therapeutic means in the practice of Medicine—thanks to the untiring efforts of M. Trousseau. Nor have I any hesitation in saying that, from the perfection to which the instruments have been brought, the operation, as regards its manual execution, is one of great facility. All but free from pain, exempt from every danger, and never hurtful, nothing but this operation can, in certain cases, free us from the impending danger.

Let us now consider, what are the circumstances in which thoracentesis is especially indicated? The three principal are these:

1st. Where there is much effusion, and the whole of one side of the thorax is dull on percussion, and the respiratory murmur is heard only over a very small extent. In these cases of great effusion, patients are seen in very different states: some suffer only debility and depression, or at most slight difficulty of respiration and some palpitation of the heart; others are oppressed with excessive dyspnœa—the respiration is hurried, the pulse is small and scarcely to be counted, and the face is oppressive of the utmost anguish. In cases such as the last all are agreed, and in these cases every one will perform thoracentesis. Of course I do not speak of those who regard the existence of tubercles as a counter-indication. In the former case the operation is, in my opinion, no less urgent; and this is the opinion of an immense majority of the Profession.

2nd. When the effused fluid is in small quantity, but increases rapidly for twenty-four, thirty-six, or forty-eight hours, and there is reason to fear repletion of the pleural cavity; here, again, do not hesitate, for there is reason to fear the occurrence of fatal syncope from compression or displacement of the heart. Recollect, moreover, the history of the patient recovering from typhoid fever whom I was so unfortunate as to lose, and could not tell what was the matter.

3rd. When the effusion is small in quantity, but of three or four weeks' standing. The repeated application of large blisters has, in such cases, been without success; nitrate of potassa and other diuretics have been used without advantage; the line bounding the dull part of the chest remains the same, and the general state of the patient grows worse: under these circumstances, wait no longer, but have recourse to thoracentesis. Your patient will not only take no harm from the operation, but may be completely cured in a few days.

To these three principal indications I would add a fourth, which has reference to the patient's age. If what I have just said to you be applicable in the case of adults, it is still more so where the patients are children or old people; but for different reasons. In children, on account of the activity of the secretory functions, the pleuritic effusions are produced with great rapidity, and you have, in such cases, to apprehend fatal syncope. When the effusion has existed for some time and is then absorbed, owing, in part, to the flexibility of the ribs at this period of life, the thoracic parietes of the same side shrink considerably, and the chest then presents those frightful deformities so well described by Laennec.

But in old people, on the other hand, there is no reason for fearing these deformities of the chest. The ribs, being less flexible, will resist the atmospheric pressure and the shrinking of the false membranes; and if I mention the energy with which secretion is carried on in the young, we have here, on the contrary, feebleness of absorption. In fact, a chronic, stationary state is the predominant character of pleuritic effusion in old persons. In such subjects, after one or two months or more, while the local symptoms plainly continue unchanged, you will see them lose their appetite, become more and more emaciated, the tongue get dry, with slight fever, in some cases, towards evening, and in the night some degree of sub-delirium. Do not wait, however, if you have the patient under your care from the first, till you arrive at such a point; and if it is only now that you are called in, practise now the operation. You will, in such circumstances, meet with success, as I have experienced, and have seen real resurrections from impending death.

THE SPIRIT OF THE PERIODICALS.

The 'Journal of Practical Medicine and Surgery' contains the following article on the *Use of Electricity for the purpose of ascertaining the Gravity of Traumatic Paralysis—Puriform Collections within the Joints of New-born Children—Good Effects of the Removal of the Protruding and Denuded Astragalus.*

"It was formerly supposed that the paralysis which frequently accompanies dislocations of the shoulder was special to the deltoid muscle, and consequent on the stretching or contusion of the circumflex nerve during the displacement of the bone. A more careful clinical inquiry into the nature of the injury has, however, shown that other muscles besides the deltoid are subject to this loss of power, although the fall which caused the disease may not necessarily have occasioned either fracture or dislocation. The muscles supplied by the radial nerve are sometimes alone affected, and occasionally those which receive the filaments of the ulnar and median. M. Nélaton further remarked that this form of paralysis results from the pressure exercised upon the brachial plexus, closely embraced between the first rib and the clavicle, which is very moveable; therefore certain nerves or nervous filaments will readily be conceived to escape compression, and partial or incomplete loss of power to be thus induced.

"An illustration of this sort of paralysis was afforded, at the Hospital of the School of Medicine, by a man who, in a fall from a considerable height, had dislocated his shoulder. The luxation was reduced with ease, and the arm kept for a fortnight perfectly steady and immovable; but when the patient attempted to use the injured extremity, he found that abduction of the limb was utterly impossible; not that the dislocation had not been well reduced, or that a fracture of the acromion or collar-bone had taken place, but because the deltoid muscle was paralysed by the mechanism above described. In this kind of injury it is interesting to know that electricity supplies us with the means of ascertaining readily whether or not the paralysis is likely to be of long duration. For this purpose the muscular contractility should be tested with the wet sponge attached to a conductor; and if the muscle responds to electric influence, a cure will certainly be effected in the course of two or three months; but, in the contrary case, the prognosis is very serious. It has been stated, it is true, that even after atrophy, a muscle might revive; but this, in M. Nélaton's opinion, is very rare, the converse being far more probable. The Professor observed that he had found traumatic paralysis indefinitely persisting, despite cauterization, atrychnia, electricity, &c. In the case under consideration, paralysis had lasted fifty days; electricity was resorted to, the muscle obeyed its influence, and a favourable prognosis, which the future course of the disease has since justified, was pronounced. The man had been admitted into hospital on the 8th; on the 9th electricity was applied for the first time, for the purpose of diagnosis, and was continued up to the 15th as a means of treatment. On the 16th the power of abduction had feebly but distinctly returned; the limb could be raised from the side; and when the arm was horizontally extended, it preserved this attitude for several seconds without support.

"This case, and others of a similar description, which we have recorded, show that in traumatic

paralysis inductive electricity is a valuable resource, and may be considered one of the most felicitous applications of this power in surgical practice.

"Another but far different disease of the shoulder-joint suggested to Professor Nélaton a few remarks on a kind of puriform arthritis, which may be called puerperal arthritis of infants. A child, aged two months, was affected in the left shoulder with a considerable swelling, presenting all the signs of a liquid collection within the capsular ligament. The mother stated that she had been ill after her confinement, and that, towards the fifteenth day, the child had seemed to suffer from the shoulder, which had become tumefied; an amelioration in the infant's condition had, however, followed, but without any concomitant decrease of the swelling of the joint.

"The disease consisted in puriform effusion within the articulation. In the children of women predisposed to puerperal affections, pus forms very rapidly in the joints. M. Nélaton related the case of a child, heir to one of the most extensive landed estates in France, and whose mother had died afterwards from puerperal fever. Eighteen days after the birth of the infant, the left knee became the seat of fluctuation, and Professor Dubois, who attended the family, called in M. Nélaton in consultation. 'If the patient were an adult,' said the latter, 'he would have nine chances out of ten against him after the evacuation of the puriform secretion. It may not be so in an infant; let us, therefore, give an issue to the pus: it is the only chance of safety.' This advice was adopted by M. Dubois: a puncture was performed, a large quantity of purulent matter escaped, and after much anxiety the child eventually recovered, and is now in sound health. We should add that, although the suppuration of the knee continued no less than two months, no anchylosis followed.

"Since that period M. Nélaton has observed many similar cases in infancy; and whenever the tumour was punctured in time, and a fistular aperture became established, the results were satisfactory. The Professor has resolved to perform the operation in the case of the child who suggested these remarks, and we will refer to it, if necessary.

"We cannot conclude this summary of M. Nélaton's clinical lecture without recording the result of an important operation performed two years ago by this surgeon, in the same hospital. A coachman, in a fall from his box, dislocated his ankle. The astragalus formed a considerable protrusion, and the excessive distension of the stretched integument brought on gangrene. The fall of the eschar exposed the astragalus; and a fortnight after the occurrence of the original accident, M. Nélaton removed this bone. After the performance of this operation the case progressed rapidly towards cure, and the following is at present the condition of the extremity: When the patient is seated, and the length of both legs is measured between the ground and a ruler placed across the basis of the patellæ, the shortening of the injured limb does not exceed ten or eleven lines. The external aspect of the foot is, moreover, natural, and with the exception of slight swelling, which yields to exercise, the patient's gait is satisfactory. The result is especially interesting, inasmuch as at one of the recent meetings of the Surgical Society the question of the removal of the astragalus in similar cases was discussed, and several of the members expressed their partiality for amputation above the malleoli, precisely on account of the alleged difficulty which the subject would subsequently experience in walking. An eminent surgeon from Nantes, Dr Letenneur, has personally witnessed three cases of removal of the astragalus, which terminated favourably. Here, therefore, are four cases which, in analogous circumstances, would, if necessary, encourage the practitioner to make every attempt to save the foot."

The following cases of *Vesico-Vaginal Perforations* are reported in the 'American Medical Monthly,' by Dr JOHN O. BRONSON:

"CASE 3.—*Cured in One Operation by New and Original Means.*—Mrs G——, native of Ireland, thirty-two years of age, was received into the New York Infirmary for Women and Children, Sept. 12th, 1859, giving the following history: She was the mother of three children, all of whom had been delivered with instruments, on account of a contracted pelvis. The last child was born still, in October, 1857, when she was in severe labour forty hours, at the end of which time her attending physician called Dr A. K. Gardner in consultation, who immediately delivered her with forceps.

"On the seventh or eighth day after, urine began to dribble through the vagina, and had continued ever since. Upon examination, a perforation of the vesico-vaginal septum was found to exist about a quarter of an inch from the cervico-vaginal junction, of a size admitting the passage of a uterine sound. Operation was determined upon. On the 14th of September, after thorough evacuation of the bowels, I proceeded as in the aforementioned case, with my patient in the same position. On account of the distance of the opening from the vulva, the successive steps of the operation were attended with some difficulty.

"In performing the denudation, the tissue was found to be dense, and of too little vitality to augur well for success; nevertheless, it was finished, and the instrument applied as in the first case. On account of the relation of the parts, however, the instrument was slightly curved, thus allowing of a better adaptation. As in the former case, a catheter was secured in place, a suppository of opium introduced into the rectum, and the patient left to rest.

"Dr George T. Elliot, Dr E. Blackwell, Dr Hughes, Dr Underwood, Dr Stratton, and Dr Cushing witnessed, and assisted in the operation.

"On the 19th the instrument was removed in the presence of Dr John Howe and Dr Hughes, and union was found to be imperfect, although no communication existed between the bladder and vagina.

"20th.—A small spot of moisture upon the sheet, yet upon examination no point was ascertainable through which water could have flowed. Nitrate of silver applied to the uncicatrized part, and a catheter passed, to be retained. 21st. Catheter withdrawn. 25th. No abnormal opening into the bladder. The vitality of the parts before mentioned evident in the cicatrization. Nitrate of silver has been occasionally applied, with good effect.

"October 30th.—Retains her urine perfectly, and has done so since the 20th, holding it for two hours.

"November 2nd.—Bed again wet. No aperture, however, existed, and another cause had to be assigned. It was believed to be inability of the bladder to retain beyond a certain quantity of urine, and that it passed by the urethra.

"The solution of the question was supported by the fact, that it never passed during the day, and only those two times at night. Commenced to menstruate.

"November 9th.—Perfect control over urinary action; cicatrization complete; discharged cured.

"In the month of November I visited her at her home, and found her happy, in the freedom from one of the most, if not the most, serious of all maladies.

"CASE 4.—*Cured in One Operation by Means of the Silver Suture.*—Mrs C——, native of Ireland, twenty-four years of age, was received into the New York Infirmary for Women and Children, October 28th, 1859.

"She had passed through the terrible ordeal of tedious labour, under the care of that curse of his race, a base pretender, who had blazoned in his window "Physician, Surgeon, and Accoucheur," and who, in every medical or surgical act, added to his daily sins that heinous crime of trifling with human life for filthy lucre.

"She suffered the galling pains of ineffectual labour for the greater part of two days, when her attendant delivered her by means of instruments, and left the patient without removing the placenta, which remained for twenty-four hours, and then was taken away by a nurse.

"As a result of such a state of things, severe inflammation of the pelvic viscera was awakened, producing sloughing of the cervix uteri, of the vesico-vaginal septum, and obliteration of the vagina to within an inch and a half of its ostium, leaving at that point, bounded by unyielding cicatricial tissue, a transverse opening into the bladder, measuring two inches in length by three-quarters of an inch in breadth. The vagina being closed above, in making a digital examination, the finger found immediate entrance into the bladder.

"The parts being not perfectly healed, and a very considerable amount of irritation existing, a strong solution of the acetate of lead and opium was prescribed and used for the space of two weeks, with the effect of presenting her fit for an operation. In considering the condition of the parts, I found two of the indications for which my instrument was devised fulfilled by the cicatrix. Motion was destroyed, and there could be no sliding of one edge upon the other, for bands extended from ischium to ischium, holding them more firmly than any mechanism. It was decided, therefore, to make use of the interrupted suture, as all that was required was simply to maintain the opposing borders in close contact. Accordingly, on the 11th of November, in the presence of Drs Blackwell, C. K. Briddon, Aigner, C. A. Budd, Hughes, B. L. Budd, Cushing, and a number of pupils, I proceeded to denude the border of the opening, after the manner described in the first case, and applying five sutures of silver wire, I made a very free transverse incision on the posterior side of the wound, to free the parts as much as possible from direct traction. The patient was then arranged as in the preceding cases, and left to await the result.

"On the tenth day after the sutures were removed, and although they had produced a considerable amount of ulceration, union was complete, and the patient was able to retain her urine entirely. Two days after she was discharged, cured; a result which I deem to have been based on the manner in which vivification was effected."

This being the Students' Number of the 'Lancet' and the 'Medical Times and Gazette,' these journals are devoted entirely to intelligence connected with the interests of students, and for their especial information.

We extract the following remarks on a case of *Piarrhœmia accompanying Acute Diabetes Mellitus* from the 'Lancet' of the 15th inst.:

"II.—*Pathology of Milky Serum.*—Milkiness of the serum has been long known by the researches of Thackrah, Buchanan, R. D. Thomson, and others, to be an ordinary physiological event attendant on the digestion of fatty or amylaceous aliment. Its occurrence during pregnancy, also (in which all the formative elements of the blood are increased), and in the blood of sucking animals, was shown by Mayer; and lactescence of the serum has been found to occur in some animals during hybernation. In all these cases, the milkiness is due both to fat and to molecular albumen. In pregnancy, the white blood-corpuscles are also in excess.

"But milkiness of serum has been still longer known as an accompaniment of certain forms of disease. The recorded cases (the earliest of which we owe to the celebrated Robert Boyle) unfortunately do not admit of any accurate numerical analysis, but I believe that the following summary will be found approximatively correct.

"(*a.*) The great bulk of the cases have occurred in connection either with alcoholism or with diabetes mellitus.

"Of alcoholism, nine cases are recorded. To these must be added the unenumerated cases of J. Frank.

"Of diabetes, seven cases are published (including the present). To these must be added the unenumerated cases of Dr Babington.

"Next in order come pulmonary diseases, of which there are six cases on record.

"Of albuminuria, one case is given by Dr Christison; 'several' are alluded to by Dr Bostock.

"The hæmorrhagic diathesis appears to have been observed in four instances.

"Morgagni gives two cases of 'malignant fever.' The diagnosis in these is not free from doubt.

"One case has been observed accompanied by peritonitis, and one by gout. John Hunter saw a case in which fatty blood was taken from a man bled for an injury to the head. This was no doubt an accidental coincidence.

"Finally, in seven of the recorded cases, the clinical history is either wholly absent, or too vague to allow of diagnosis. (R. Boyle (3), Traill, Caventou, Mareska, Quevenne.)

"(*b.*) It is observable that in most, if not all, of the cases of alcoholism, the lactescence of the serum was occasioned by free fat alone.

"It would also appear to have been due to the same cause in all Dr Babington's cases of diabetes, in those of Marcet and Rollo, and in the present instance. Dr R. D. Thomson saw a case of diabetes in which molecular albumen also was present. Darwin's and Abernethy's cases are uncertain. In Leubuscher's case, lactescence was caused by free fat and an excess of white blood-corpuscles.

"In the pulmonary group it seems to have been caused by fat alone in four cases. In one (recorded by John Hunter), albumen was also present; in another (by Mr Gulliver), a yellow precipitate fell on addition of ether. It is probable that this consisted of albumen previously held in suspension by combined fat.

"The cases in which molecular albumen appears to have been present in considerable quantity are these two (of pulmonary disease), all the cases of albuminuria mentioned by Dr Bostock, the uncertain case recorded by Dr Traill, and the solitary instance of gout.

"(*c.*) The serum has been analysed in several cases. Of the analyses, the most important are those of Traill, Lecanu, Bertazzi, Mareska, and Heller. The general results are as follows:—

"*α.* In one case (Bertazzi's) the only peculiarity consisted in the presence of an excess of fat (10 : 1000) at the expense of the other elements of the so-called 'extractive.' In all the others the solids of the serum were in excess, varying from 164 : 1000 to 206 : 1000. The normal average proportion, according to Scherer, is 93·4 : 1000. Notwithstanding this fact, the specific gravity of the serum was below the average (1023) in Heller's and in Traill's cases, and apparently in all Dr Babington's.

"*β.* Fat is, of course, in excess in all these cases. It varies from 24·4 : 1000 (Traill) to 117 : 1000 (Lecanu). In this case, however, the enormous excess is made up by 108 parts of cholesterine. The greatest amount of saponifiable fat recorded is 50·473 : 1000 (Heller).

"*γ.* The proportion of albumen is not constant. Scherer's average for healthy serum gives 75·2 : 1000. Bertazzi's case nearly corresponds with this standard. Two cases (Mareska's and Lecanu's) fall below it (64 : 1000). The other two exceed it very considerably (103·791 : 1000, Heller; 133·1 : 1000, Traill).

"*δ.* In two instances (Mareska's and Caventon's) the reaction of the serum was acid. In the present case and in Leubuscher's, it was neutral.

"In Leubuscher's case, no free NH_3 was extricated from the blood by heat. In the present case a volatile alkali was so liberated, but much more copiously from the splenic than from the hepatic (or fatty blood).

"(*d.*) The fibrin and red corpuscles of the blood have been estimated in only one analysis (Heller's). The former amounted to 4·72 : 1000 (about double the average); the latter to 80·13 : 1000 (the average being 141·1).

"In the present case, in Lecanu's, and apparently in Leubuscher's, there was an almost total deficiency of coagulable fibrin.

"In Leubuscher's case the white blood-corpuscles are stated to have been in excess.

"(*f.*) Such, I believe, are the principal facts ascertained with respect to milkiness of the serum or of the blood, not dependent upon leucæmia.

"Briefly, the results are as follows:

"1. Milkiness of serum (or blood) is due to presence of free fat, or of free fat with albumen in a molecular form. It is probably never due to molecular albumen alone.

"2. It is a physiological result of digestion, pregnancy, lactation, and hybernation.

"3. It is an occasional pathological result of chronic alcoholism, diabetes mellitus, pulmonary disease, albuminuria, and, perhaps, some other disorders.

"4. Lactescence of serum from free fat alone appears especially to accompany alcoholism and diabetes mellitus. The conditions favouring the presence of molecular albumen are still very obscure; they appear related in some way to albuminuria.

"5. The serum is sometimes neutral and sometimes acid in this disease. It may contain no free alkali.

"6. The albumen of the blood may be normal, or defective, or in excess.

"7. Coagulable fibrin is sometimes entirely absent, or nearly so.

"8. In the present instance the source of the fat in the blood was the liver.

"(*g.*) Before attempting to construct upon this foundation an hypothesis which may give a probable explanation of fatty blood, it may be worth while to review, very shortly, the few opinions which have been already promulgated upon this subject.

"The earlier observers, from Robert Boyle to Hewson, were unanimous in referring 'white blood' to the passage into the circulation of unaltered chyle, or even (as Tulpius) of unaltered aliment. This opinion was indeed true, but only half true; and its insufficiency was demonstrated by Hewson, who observed several cases of disease, accompanied by milky serum, in which the patients had taken little or no food for several days.

"From this period the subject appears to have remained in abeyance, until Caventou's case gave a new and purely chemical turn to the inquiry. In this case the serum had an acid reaction; and upon this fact Raspail based an explanation by no means devoid of plausibility. He held that the fat was set free in the blood for want of a free alkali to hold it in the form of a soap.

"This view is obviously true so far as it goes; but it seems almost to imply a confusion of cause and effect. Acidity of the blood is, doubtless, capable of setting free all the saponifiable fats normally present in that fluid (say 1 : 1000); but it cannot create fat. The hypothesis is, therefore, quite inadequate to explain the presence of the large amounts of fat in the blood noted in the previous analyses.

"It seems, therefore, far more reasonable to suppose that the excess of fat had exhausted the free alkali of the blood, than that the abstraction of any amount of alkali could have liberated such enormous quantities of fat. This doctrine has, nevertheless, held its ground, and has contributed not a little to the so-called 'alkaline' treatment of diabetes mellitus.

"The next opinion which I have to notice is that of Dr Babington, to whom the literature of this subject is so highly indebted. This distinguished observer seems to have been disposed to regard piarrhæmia as a true fatty degeneration of the albumen of the blood, basing his views partly upon the low specific gravity of the serum in these cases (which he had been the first to observe), and partly upon the peculiar case recorded by Caventou, in which it was erroneously supposed that no albumen was present in the blood at all. But it has been already shown that the specific gravity of the serum is no indication of the amount of albumen which it contains; that in Caventou's case, the lactescence, if not due to albumen, was certainly not due merely to fat, and that, in two cases at least, both fat and albumen were present together, and both in large excess. This explanation must, therefore, it seems to me, be abandoned.

"Another has been proposed by Rokitansky, also based upon the idea of fatty degeneration. He thinks milky blood due, 'in a considerable number of cases,' to fatty degeneration of the colourless corpuscles of the blood, previously formed in excess in that fluid. He regards it, therefore, as a modification of leucæmia; and supports his opinion by the statement that milky serum has been generally observed under circumstances ordinarily accompanied by an excess of white corpuscles.

"This statement, however, seems to require considerable modification, at least so far as regards cases of disease. In one, indeed (Leubuscher's), the colourless corpuscles are said to have been in excess; and, in four of the earlier cases, that hæmorrhagic tendency was noted which so often accompanies leucæmia. But, with these exceptions, the diseases attended by fatty blood (alcoholism, diabetes, pulmonary disease) are not those especially related to leucæmia; and the pathological changes most constantly noted in leucæmia (enlargement of spleen and mesenteric glands), appear never to have been observed in cases of fatty blood. In the subject of this paper the spleen was remarkably small, and weighed only three ounces and a half. Rokitansky, however, also allows the direct introduction of fat into, and the liberation of combined fat within, the blood to be possible causes of milky serum.

"The only remaining opinion which requires notice is that of Virchow, who has treated the subject quite incidentally in a note to his valuable memoir upon Fibrin. He regards milky serum, in pathological cases, as essentially dependent upon the non-elimination (non-combustion) of fat, and its consequent accumulation in the blood. The appearance of molecular albumen he appears to consider only a secondary phenomenon; the slow saponification of the excess of fat abstracting from the albumen of the blood the alkali required to keep the latter in solution.

"The first half of this explanation is certainly, in many cases, correct. The other involves some difficulty; for, if it be true, it seems impossible to account for the occurrence of large quantities of free fat, in acid or neutral blood, without the presence of molecular albumen, as was the case in three of the instances collected above.

"The conclusions which I should venture to draw from a comparison of the facts collected in this paper are as follows:—

"1. Piarrhæmia consists in an excess of saponifiable fat in the blood, not in the mere liberation of fat from its combinations.

"2. The excess of fat in the blood may be the result of two causes—viz.:

"(*a.*) The excessive ingestion of fat (as in piarrhæmia during digestion).

"(*b.*) The diminished elimination of the same (as in hybernation and pulmonary diseases).

"It is not quite clear to which of these categories alcoholism belongs. It is conceivable that its elements may be directly converted into fat by deoxidation; but it seems more probable that the conversion is effected indirectly, the hydrocarbon of the alcohol attracting to itself that free oxygen which would otherwise have been employed in the combustion of the fats of the food, and so permitting the accumulation of the latter in the blood.

"3. Fat, if directly ingested, may enter the blood with the chyle through the thoracic duct; but it is clear from the present case that it may also be elaborated in, and absorbed directly from, the liver.

"Piarrhæmia is not a result of diabetes mellitus, for either may exist without the other. Both seem to be the consequences of the same derangement of the functions of the liver which overloads the blood, sometimes with an excess of sugar alone, sometimes with an excess of sugar and fat combined.

"Why the liver should deal so differently in different cases with the hydrocarbons submitted to its influence, it is hard to say. It seems not improbable that sugar alone is elaborated in the first instance, and that the excess of fat is the result of a deoxidation of this substance; for the conversion of sugar into fatty substances is not only capable of being effected experimentally (as in the production of butyric acid by fermentation of sugar under the influence of casein), but has been shown to take place in the animal economy, in the formation of wax by bees fed only on sugar.

"5. The pathology of blood milky from molecular albumen must be considered as still almost wholly negative. It is probably never an independent affection; but neither is it a mere accidental consequence of piarrhæmia. Its apparent relation to albuminuria seems to point to some organic change in the constitution of the plasma of the blood itself."

Dr T. A. Carter contributes to the 'Medical Times and Gazette' of the 15th inst. some suggestions for the improvement of *Paracentesis Abdominis* in cases of Ascites, which we reproduce:

"The operation of paracentesis abdominis is now seldom or never resorted to in cases of ascites depending on organic disease, except with the view of alleviating certain symptoms, which arise as a consequence of the accumulated fluid interfering by its pressure with the physiological actions of the abdominal or thoracic viscera. The operation must, therefore, be regarded as a mere palliative, and not as a curative agent in the treatment of structural lesions; and as such I have to speak of it in the present instance.

"At one time much discussion prevailed touching the relative merits of early and late tapping in cases of abdominal dropsy, and even at the present day some difference of opinion is maintained; but the great majority of physicians are now, I think, agreed that the operation should only be resorted to when such symptoms appear as indicate dangerous interference with the performance of some function necessary to

life; or, when the sufferings o the patient are so acute as urgently to demand the temporary relief attainable by surgical aid. This opinion, then, which is based upon observation, may be fairly interpreted as signifying that tapping, though sometimes a necessary expedient, is always a very dangerous one; and every practitioner who has profited by opportunities of witnessing the effect of this palliative measure upon ascitic subjects, will be able to call to mind cases in which, judging from the previous general condition of the patient, life might long have been carried on, could relief have been obtained by the employment of a milder remedy. In those instances, therefore, in which paracentesis is imperatively demanded on account of the powerlessness of our hydragogue remedies, it behoves us to take every precaution for the avoidance of those procedures which physiological and pathological science point out as likely to exercise an injurious influence upon the already enfeebled constitution of the patient. Now, it has appeared to me that sufficient attention has not hitherto been paid to the teachings of physiology and pathology in the performance of this operation, and that to this cause must, in some measure, be ascribed the rapidly fatal results by which it is so frequently followed.

"In order that I may be enabled to point out, and comment upon, what I consider to be the chief defects of this operation, as well as to offer some suggestions for its improvement, I shall briefly describe the manner in which it is usually conducted. The patient being placed in a sitting posture, is encircled with a broad flannel bandage, the ends of which are held by two assistants, who, by this means, exercise pressure upon the abdominal walls. The operator having determined upon the most suitable point for the puncture, makes an aperture in the bandage at this spot, and then proceeds to thrust a full or medium-sized trocar and canula perpendicularly through the abdominal walls. This done, the trocar is withdrawn, and the entire quantity of fluid (often amounting to several gallons) is removed. In the mean time, the patient's strength is supported and syncope prevented by the administration of alcoholic stimuli. On the canula being withdrawn, the wound closed, and the bandage carefully adjusted, the operation is complete.

"The marked and immediate relief afforded by this very simple procedure is, of course, highly satisfactory to both the patient and the practitioner; but in estimating the value of this remedy, as of some other for the time being satisfactory remedies, such as bloodletting, it is necessary not only to direct our attention to the present benefits which they confer, but also to take cognizance of the remote consequences by which they are followed.

"It too frequently happens, a few hours after the system has partially recovered from the inevitable shock which it has sustained, that pain and tenderness on pressure are felt over the abdominal region, followed by re-distension, which together call for the relaxation or entire removal of the bandage. The distension continuing to increase, often occasions the opening up of the canula-track, and the escape of a quantity of serum, which not merely tends to weaken the patient, but by its saturating the bed-clothes proves a source of great annoyance and discomfort. This state of affairs is generally, however, of but short duration, for the pulse grows rapidly quicker and weaker, exhaustion progresses, and death soon closes the scene. The patient dies of acute traumatic peritonitis, induced, unquestionably, by the operation which I have described.

"The first and gravest objection which I have to urge against the operation is the removal of the entire quantity of fluid contained in the cavity of the abdomen; a practice which is, in my opinion, not only unnecessary, but in the highest degree prejudicial to the patient. It is unnecessary, because, as I have before said, our object in tapping is but to alleviate a symptom, or series of symptoms, arising from the pressure of the ascitic fluid, and this end will be as effectually attained by the abstraction of a small portion of the fluid as by the withdrawal of its entire quantity. The practice is injurious, because the most abundant experience testifies to the fact that all large and sudden evacuations of any kind, especially of albuminous fluid, produce, in addition to the temporary shock, a secondary depressing effect, which is sometimes even of long continuance. The complete evacuation of the peritoneal sac is, furthermore, injurious in consequence of the bloodvessels losing the equal support afforded by the ascitic fluid, the result being a tendency to congestion and re-effusion into the abdominal cavity.

"The evils to which I have just alluded are, doubtless, to some extent, successfully combated by the exhibition of cordials and the application of the bandage; but it admits of question whether the bandage, especially if tightly drawn, does not of itself often produce mischief by bringing roughly in contact organs which have long been separated by a layer of fluid, and thus operate as an exciting cause of peritonitis.

"As I have been unable to discover any advantages likely to be derived from the employment of a large or moderate-sized trocar in tapping for ascitis, and as several valid objections may be raised against their use, I would suggest a modification of the operation in this particular also. The only sufficient reason, indeed, that can be offered for the use of large instruments in any case of paracentesis is, that the fluid to be drawn off may be so viscid or gelatinous, as to be incapable of running through a canula of narrow bore. But as this condition is never observed in examples of pure peritoneal dropsy, and as we know that the liability of wounds to inflame and become dangerous is, *cæteris paribus*, exactly proportionate to their extent, it must be evident that the smaller the instrument employed in puncturing the abdominal walls, the better; for the less will be the chances of peritonitis. What further remarks I have to make on the practice of tapping as usually adopted, will be reserved until the modification which I am now about to propose has been described.

"Let the patient, then, instead of being encircled with a flannel bandage, be simply placed in the sitting posture, and directed to take a deep inspiration, and hold the breath until the puncture has been made. Let the operator, after having selected the smallest size of trocar, thrust it obliquely upwards and inwards through the abdominal walls, and, allowing the canula to remain, draw off just so much fluid as will relieve the prominent symptoms. This being accomplished, the canula must be withdrawn, and a piece of strapping placed over the external wound. A little wine or brandy may be administered during the operation.

"I have here dispensed with the bandage as being unnecessary, because the abdomen will be sufficiently tense for the purpose of puncturing, and the shock to be apprehended from the operation so slight as not to require us to resort to such an expedient.

"My object in recommending that the trocar should be made to traverse the abdominal parietes obliquely is, that by this contrivance the leakage which sometimes occurs after tapping in the ordinary fashion may be avoided; for it will be readily understood that if the trocar-track be made oblique, the outward pressure of the residuary fluid will completely obliterate the passage as soon as the canula is withdrawn; whereas, if the passage be made at right angles to the abdominal walls, the tendency of the accumulated fluid will be to open up the track of the canula, and so escape. Whether this precaution will be found necessary in tapping with the very fine trocar which I have recommended, must be left for experience to decide; this much, however, is certain, that large quantities of fluid do sometimes trickle away after tapping, in the usual manner, with a trocar of not more than one-tenth of an inch in diameter. A simpler and perhaps more effectual method of giving obliquity to the trocar-track, would be to draw the skin upwards, and push the trocar directly through the abdominal walls, a little below the point where tension is being exercised. On withdrawing the canula and allowing the tissues to resume their ordinary relations the wound would necessarily assume the desired obliquity.

"It is of course impossible to lay down any strict rules concerning the quantity of fluid that should be withdrawn, as this must vary somewhat in each individual case; but I am disposed to believe that from one to two pints will be amply sufficient to relieve the symptoms arising from pressure, such as dyspnœa and the suppression of urine; and I think that in every case the evacuation of fluid should be suspended as soon as the stream from the canula begins to exhibit the slightest indications of flagging; for as no artificial compression is exercised by means of the bandage in this operation, the retardation of the stream will indicate that all dangerous pressure has been removed; and this, as I have before said, is the sole object to be gained by performing paracentesis in cases of ascitis depending upon the existence of organic disease.

"In conclusion, let me remark that if the modification of paracentesis which I have now proposed be found, upon trial, to be as free from danger as I am led from theoretical considerations to suppose that it will, I would suggest that the operation should be resorted to at a much earlier period than has hitherto been customary in these cases — so soon, indeed, as the hydragogue remedies have ceased to produce the desired effect, and before the viscera have become compressed and displaced, and the blood saturated with urea and other excremental poisons. And I would further submit for the consideration of those interested in the amelioration of our art, whether it would be preferable to draw off a small quantity of fluid in the way I have proposed, and thus afford the kidneys an opportunity of resuming their functions, and so of ridding the system of water through its natural channels, than to attempt its removal by the employment of drastic purgatives, which frequently operate with such violence, as of themselves seriously to jeopardise the life of the patient."

We quote the following interesting case of *Wasting Palsy* from the 'Dublin Medical Press:'

"Andrew McCaughry, a farmer from the county Longford, was admitted June 7th, 1860.

"*General Physiognomy.*—He appears, as he is, a man about fifty-two years of age, of sanguineo-phlegmatic temperament, of very moderate muscular development, but still having a general look of health. His hair is just turning grey, and the arcus (or rather circulus) senilis is well marked in both eyes. He stands unsteadily, in a manner evidencing want of power in the right leg, and the following abnormal conditions are observable on the right side of the body:—The shoulder is considerably flattened and depressed, the arm consequently hanging lower than the opposite one. The elbow-joint is bent to a right angle, and the forearm kept close to the chest, as if supported in a sling. The proximal phalanges of the fingers are extended, while the others, with the thumb, are curved towards the palm, and the muscular parts of the entire extremity are considerably diminished in size. This wasting is particularly marked in the muscles of the thumb. The situation of the pectoralis major exhibits no projection, but rather a series of depressions corresponding to the intercostal spaces, which latter are all slightly sunken in; the inferior angle of the scapula projects somewhat; the thigh has lost its muscular outlines, and assumed a rounded form. There is no distortion due to any of the facial or orbital muscles.

"*History.*—The patient states that he is married, and has had nine children, of whom seven are living and healthy; none of his family have had any disease similar to his; he has always been otherwise very healthy, and tolerably temperate; has never been hard-worked nor much exposed to bad weather, nor has he been in the way of any conceivable mineral poisoning; but he states that a couple of years ago he suffered much anxiety of mind from family affairs.

"September, 1859.—Without any obvious cause, and without any concomitant derangement of health, he now felt a gnawing pain and tenderness about the upper dorsal vertebræ; this lasted about two months, and in November, 1859, disappeared; but a similar pain was immediately felt in the right shoulder, whence it spread down the arm and forearm to the wrist, more severe on the internal side. Coincidently with the pain, the shoulder and arm felt stiff and weak, and a stinging pain and numbness, with impairment both of feeling and of motor power, commenced in the fingers, and travelled upwards to the elbow, the loss of power over which and the fingers having gradually increased to the present time.

"January, 1860.—He felt a numb pain along the course of the right sciatic nerve, which, after lasting a couple of months, disappeared, but left a sense of numbness and impairment of feeling of the entire limb; coincident with this there was a temporary sensation of coldness of the extremity,

and, according to his statement, it was not only a subjective, but also an objective symptom, being perceptible to others as well as to himself. The ankle also swelled somewhat, and for a while.

"March, 1860.—His right forearm and hand were now attacked with a temporary coldness similar to what had occurred in the leg, and the wrist swelled for a while. Now, for the first time, he experienced a diminution of power in the right lower extremity, manifested most strikingly by a liability to trip over the slightest obstacle, and accompanied by a general sense of weakness across the lumbar region.

"In addition to the above, the following symptoms are complained of: Three organs of special sense have been affected during the last two or three months. There have been impairment of smell, slight dimness of vision, and muscæ volitantes in the left eye, and slight deafness and tinnitus in the left ear. The urinary organs have been deranged three times during the last two months, with brief attacks of pain in the hypogastrium, accompanied by some deposit in the urine. The bowels, for the last month, have been obstinately constipated. Constant headache has been present during the last fortnight; an aching pain across the forehead, which, however, it may be observed, disappeared upon the administration of some purgative,

"*Details of Present Condition.*—The above symptoms, with the exception of those noticed as temporary, continued to the present time. The mental powers are quite unimpaired. The countenance, pulse, tongue, and urine present nothing abnormal, and there is no tenderness over any part of the spinal column: but not so the muscular and nervous systems.

"*Muscular System.*—The following description applies to the right side only, the left remaining unaffected.

"All the muscles of the upper extremity are atrophied; some more, some less; those of the arm less so than those of the forearm. The biceps differs from all the others in feeling tense and hard, which, however, is due to the suspension of the forearm from it, at a right angle to the arm. When relieved of this weight, it presents the same remarkable flabbiness which characterises the others.

"In the forearm the extensors and the supinator longus are much less atrophied than the flexors and pronator teres. This part, therefore, is flattened in front, rounder behind, and almost normally rounded on the external aspect. The following measurements show the difference in size of the two forearms; but it is obvious that they do not indicate the exact amount of diminution, the right being normally rather larger than the left. Two inches below olecranon—left, 10¼ inches; right, 9⅞ inches. Three inches above styloid process of radius—left, 7¼ inches; right, 6¼ inches.

"The thenar muscles are much wasted, the hypothenar less so. In the angle between the thumb and index finger, little more than a lax web, consisting of two layers of skin, can be felt. The dorsum of the hand presents rather a concave appearance, and depressions corresponding to the dorsal interossei, muscles not usually affected in lead-poisoning.

"The voluntary motor powers are greatly impaired; in fact, the only motions of which the upper extremity is capable are, abduction of the arm to an angle of about 45° at the shoulder-joint, and very slight pronation and supination of the hand. But, under the influence of galvanism, all the muscles act, as far as can be ascertained, though to a variable degree. Thus the deltoid acts well, and its individual fasciculi can be seen contracting; the supinator longus contracts vigorously, the pronator teres and digital flexors scarcely at all.

"The cutaneous sensibility of the right arm is complete down to the elbow, but below that is nearly absent. The patient cannot feel pinching unless his sense of sight calls attention to it, and he can scarcely perceive the contact of a sharp point.

"*Right Lower Extremity.*—He uses this as a person affected with hemiplegia would, rather dragging than lifting it. The muscles, though not so much atrophied as those of the arm, are very flabby, and their power over the joints is nearly, but not entirely, gone; he can scarcely flex the hip-joint. They contract well under galvanism. The sensibility is much impaired from the great trochanter down. The sense of touch is curiously perverted on the sole of the foot. In one respect it is exalted, for the contact of any object, however rounded, produces pain, more or less acute, in another; it is impaired, for he cannot distinguish a spherical surface from a point. This extremity affords a good example of reflex movements independent of sensation and will, a slight touch on the skin, especially that of the foot, being followed by a rapid jerking withdrawal of the entire limb.

"*Fibrillary Tremors.*—This symptom, described by Cruveilhier, and consisting in a tremulous clonic contraction of the minuter fasciculi of the muscles, visible through the skin, was observed in this case only in the following muscles, all on the right side: deltoid, dorsal interossei of hand, palmaris brevis and ext. digitorum longus pedis.

"*Treatment.*—The treatment was commenced on the 8th June, and consisted in full diet, occasional warm baths and purgatives, which relieved some slight pains in head and joints; blistering over lumbar region; pil. Plummeri gr. v. ter in die; changed on June 27th to calomelanos gr. i., pulv. antim. gr. ii., ter in die. In addition to these electro-magnetism was used daily in the following way: the conductors of the machine were applied over the belly of each muscle at a distance of about two inches apart, and for the space of one or two minutes.

"*Progress, and Condition on Discharge.*—On the 20th of June, that is on the thirteenth day of the treatment, the first distinct signs of improvement in the motor and sensory powers were manifest. Domestic affairs not allowing the patient to remain any longer from home, he was discharged at his own request on the 5th of July, and his condition the day before leaving was as follows:—The dimensions of the forearm remain the same, the muscles having apparently neither enlarged nor diminished. *Motor powers:* The muscles in general have become decidedly more sensitive to the electric stimulus, and several of them are more under the control of volition than they were at first: accordingly he can raise the humerus now so as to form a right angle with the trunk; he has some slight power of flexing the elbow, not possessed before; and he can flex the thigh upon the trunk and walk with much more steadiness and firmness than he could when entering the hospital. The reflex movements of the leg already alluded to can scarcely be excited now. The cutaneous sensibility both of arm and leg is considerably improved, judging both from his own statements and from experiment. The bowels are no longer constipated, but are perfectly regular. The affections of the organs of special sense, mentioned above, continue without any improvement. It may be observed that the mercury did not produce any of its usual effects, except that, during three or four days before leaving, the gums were very slightly sore.

"The following general statements appear to be applicable in the above case:—

"1. The affection of the arm was preceded by notable pain and tenderness in the adjacent part of the spinal column; that of the lower extremity was not.

"2. In both extremities, in addition to impairment of sensibility and motor power, there were these symptoms: pain along the course of the great nervous trunks, pain at their remote points of distribution, temporary diminution of temperature, and temporary swelling, at the wrist in the upper extremity, at the ankle in the lower.

"3. The contractility under galvanism and the amount of atrophy of the muscles seem to be inversely proportioned one to the other. The greater the atrophy, the less the contractility.

"4. The varying extent of atrophy seems, to some extent, to correspond to the source of nervous supply; for the muscles supplied by the musculo-spiral are much less diminished in size than those supplied by the median and ulnar nerves.

"In compliance with Dr Benson's wishes, I have detailed the particulars of this case of wasting palsy, or 'Cruveilhier's Atrophy,' with some minuteness. Because,

"1st. It is a rare affection.

"2nd. It has only of late attracted much attention.

"3rd. It is apt to be confounded with other forms of paralysis.

"4th. Its pathology is not very satisfactorily ascertained; and,

"5th. Its treatment is not quite settled, although electricity and exercise seem to be beneficial.

"For the best account of the disease in our language, consult Dr Roberts' essay on 'Wasting Palsy,' an able monograph by a gentleman who formerly studied in this city."

Mr John K. Barton contributes to the 'Dublin Hospital Gazette' the annexed *Case of Diphtheria.*

"Upon the morning of Sunday, the 22nd of July, I was sent for to an institution for training female servants in Stephen's green, to see one of the girls, whom the matron stated had been taken very ill on the previous evening, and in spite of some means employed was rapidly getting worse. I found the patient to be a delicate girl of about twenty-seven years of age, for whom I had prescribed some time before for constant headache and debility. She now complained of a terrible pain in her head, and that her throat was so sore she could not swallow anything. Her whole body was covered with a profuse perspiration; her pulse was weak and compressible. She had had a shivering upon the night before, and still, whilst bathed in perspiration, complained of feeling cold. The tongue was covered with a whitish fur, and was swollen at its root, particularly upon the left side. The left tonsil was swollen, and the most prominent part of it covered with a white exudation. The uvula was œdematous; the arches of the palate and back of the pharynx were redder than natural, but there was no ulceration nor any white patch except that upon the left tonsil, which was not by any means loose or abundant, but quite close, corresponding to what is described by the French authorities upon diphtheria as the *Lichenoid* form of exudation. I touched the patient's throat freely with the solid nitrate of silver; ordered her a mixture containing ten drops of muriated tincture of iron, and ten grains of chlorate of potash in the dose, every third hour, with some wine-and-water during the day. I saw her again at seven o'clock the same evening; all the symptoms observed in the morning were still present, but in an increased degree. She was decidedly worse; the pulse was very small and thready, the body bathed in perspiration. The patient lay apparently only half conscious of anything going on about her, and had been talking during the day in an incoherent manner. The medicine and wine had been got down her throat with great difficulty, swallowing was so painful. I made a searching examination of the throat: the white exudation extended now not only over the left tonsil, but over part of the velum, the uvula, and slightly the back of the pharynx, while the œdematous swelling of the velum and uvula was now very marked. Tongue protruded with difficulty, moist and swollen at the root. I now had a drachm of nitric acid mixed with an ounce of honey applied freely to the throat twice during the evening. A teaspoonful of brandy was given every hour in a little water, and the medicine continued every third hour.

"Upon Monday morning I found she had not slept at all during the night. Only very little of the brandy had been swallowed. The pulse, however, was somewhat better than it was the night before. I now removed her to hospital, as proper attention could not be given to her where she was.

"Upon her admission an examination of her throat was made under a good light, when masses of soft, white exudation were seen covering the left tonsil, uvula, and back of pharynx; but so swollen were these parts found, that the parts covered by the exudation looked like the bottom of a sloughy ulcer.

"The same mixture of nitric acid and honey was twice thoroughly applied, and a mixture ordered of the muriated tincture of iron and chlorate of potash—20 drops of the former and 20 grains of the latter in every dose—to be taken every second hour. At every alternate hour she is to get a teaspoonful of brandy. Upon the evening of the same day she was going on favourably, and upon Tuesday morning I found she could swallow better.

"Her headache, which up to this time had been intense, had disappeared. Pulse a little stronger. Exudation had not extended at all in the throat; if examined now for the first time, it would most likely be presumed to be a bad sloughy ulceration of the throat. Pains in the ears were complained of. There is but slight swelling of the neck externally. The throat was well touched with the acid solution. Three ounces of brandy were given in the day, also beef-tea, and the mixture continued every third hour. The disease did not extend after this. Upon Thursday there was a very marked improvement in her

general appearance. The false membranes were not all thrown off yet; they were loose, and emitted a very offensive smell. Upon the following day they all were expectorated, the throat then presenting a natural appearance, evidently having suffered no loss of substance. Just a week after her admission she left the hospital, being quite well, with the exception of a feeling of great weakness, and at present is in good health.

"It is unnecessary to make any remarks upon this case, so much has been so ably and recently written upon this disease. But inasmuch as very few marked cases of the kind have appeared here, it is well to record the symptoms; and the energetic plan of treatment will, perhaps, be thought worthy of imitation, inasmuch as it was followed by a favourable result.

"I should mention, in connection with this case, that a short time before a young woman, in the same institution from which the patient came, was under my care for a very bad ulcerated sore throat, accompanied with constitutional disturbance and debility, several examples of which I have seen during the past spring. This patient was a remarkably fine, healthy-looking young woman, whose duty was to attend in the shop, where, the day before she was taken ill, she perceived from the breath of a customer, to whom she was attending, a most disagreeable smell. That night she had a shivering, and in the morning I saw her and found her throat inflamed, and ulceration already commenced. She had, however, recovered perhaps a week before the girl whose case I have related took ill. A few days after her discharge from hospital, the matron of the same institution complained of feeling ill with sore throat; upon examining her mouth, two small white spots, each about the size of a fourpenny-piece, were seen, one on each tonsil. That this was an exudation was quite plain, for, although it was so adherent as to prevent its being raised off the mucous membrane, the point of a director could be pressed a little beneath its edge. There was very little constitutional disturbance. The hydrochloric acid and honey were several times applied freely, and a mixture of chlorate of potash and muriated tincture of iron ordered. Next day the exudation had disappeared, and in a day or two afterwards she was in her usual health."

The "Indian Lancet" contains the following article on the *Delhi 'Boil, or Aurungzebe*, by Surgeon FRAZER, of H.M.'s 88th Regiment:

"The Delhi boil, or ulcer, for it assumes the appearance of the former before it ends in the latter, has been known to be peculiar to Delhi as far back as authentic history can trace, and is called by the natives Aurungzebe, after that Emperor, who was a victim to this form of disease. Its existence is confined principally to the city of Delhi, being less common in the surrounding district; and at Meerut, about forty miles off, it is unknown. Some places, even in the immediate neighbourhood of Delhi, the natives declare to be perfectly exempt from it; but this may arise in a great measure from the population being comparatively few in number.

"Various theories have been propounded as to the causes which give rise to this disease; but they are so vague and unsatisfactory, that none of them can be relied on. Some attribute it to the influence of malaria; but then it prevails most in the winter season, when malaria does not abound. Others consider that it arises from an impoverished state of the blood, caused by bad living and impure air; but it occurs in those who live well, occupy good houses, and use all means in their power for obtaining the best of everything—air, exercise, and houses included.

"The natives agree in the theory of its arising from the use of the water of Delhi, which is impregnated with saline salts, chiefly, I believe, the nitrates. I am inclined to adopt this hypothesis, for the following reasons:—

"1st.—Although I have no means of analysing the water of the wells of the city of Delhi, I am induced to believe that it must be impregnated with the same salts as are known to be held in solution in the water peculiar to Mooltan, and many parts of Scinde, where a very similar ulcerative disease is observed to prevail.

"2nd.—The disease is more prevalent after the rains. May not this be ascribed to the rain-water, which supplies these wells, in percolating through the soil, taking with it large quantities of the salts in solution, and thereby causing an excess in the quantity of salts already in the wells, and consequent disease to those who drink or otherwise use the water internally?

"3rd.—May not the fact of the disease being less prevalent in the dry weather at the beginning of the hot season, and before the rains, be due to the water in the wells being less scanty from daily use, and not being renewed by a supply of rain-water, and consequently less salts being held in solution in the water which remains? It follows, therefore, that these salts, whatever they may be, when constantly taken into the system, undergo chemical changes and combinations in 'the great laboratory of nature,' which, acting on the eliminating organs of the body, so alter the constituent parts of the blood as to give rise to the formation of diseased tissue.

"Whatever the cause, I have no doubt but that 'Delhi ulcers' are a disease of the blood, and ought to be classed under the head of zymotic disease.

"I shall now endeavour to show the rise and progress of the disease in the 88th Regiment, but can only do so imperfectly, not having been with the corps prior to February 1860. The regiment arrived in Delhi in the month of February 1859. In June the men began to be affected with troublesome sores, which appeared in different parts of the body. These were found to be most intractable, resisting all treatment; and the number of men affected became greater as the season advanced, and their greatest increase was from December 1859 to March 1860. They are now (May) on the decrease, having begun to be less frequent in April. Since about June 1859, to 30th April 1860, as many as 114 soldiers have had Delhi ulcers, and many of the officers, women, and children. A number of the soldiers have had four re-admissions into hospital from this annoying disease, which spares neither race, age, nor sex, and causes great disfigurement.

"It begins by the gradual formation of a reddish patch, raised and hard in the centre, over which the skin, at first smooth and shining, puts on a scaly appearance, becoming fainter towards the border of the spot. In the centre is a small pimple; after a time, a brownish crust forms, which is somewhat more depressed than the surrounding surface; it becomes gradually larger, particularly if picked or irritated, and it is accompanied by pain and sometimes a troublesome itchy soreness.

"While this is going on, the surrounding skin becomes of a shining light purple colour, and scaly, gradually becoming fainter in scaliness and colour as the distance from the centre is increased. If the crust is removed, a raw irregular surface is observed, which bleeds freely if roughly handled. It secretes sometimes a thin transparent secretion, or a thin greyish brown fluid; this cakes on the surface, and forms the crust, and the ulcer goes on spreading. It is usually of an irregular circular form, but it presents itself in all shapes.

"Sometimes a thick crust of a greyish white colour forms, and the ulcer underneath it is smaller and has not such a tendency to spread as in the brown crusted variety. This, however, may arise from being less picked at and irritated by the patients themselves. The raw surface consists of flabby, irregular, fungoid-looking granulations, which appear more luxuriant in the centre, and are tender to the touch. When kept clean and dry, the ulcer very quickly forms what appears to be a new skin, beginning in the centre and extending to the edge; but it seems as if it could only advance to a certain distance, for a raw watery line of demarcation separates it from the surounding tissue. The centre is now hard and dry, like parchment, and pressure discovers that it has nothing adherent to it underneath. If removed by a poultice, the raw surface is discovered to be depressed in the centre, and secreting the thin peculiar fluid, which, if left alone, would form the thick, brown, dirty-looking crust, with a well-defined watery line of demarcation between it and the sound skin; becoming, if the sore is situated on a part that admits of much motion, a deep sulcus.

"When the Delhi ulcer heals up, it leaves a cicatrix depressed in the centre, with raised and slightly indurated edges, and a purple, scaly surface. It soon breaks out again, accompanied by the appearance of some new ones in another place. They are more common on the upper extremities and face than on the lower limbs, and are more rarely observed on the trunk.

"While they are in progress no traces of constitutional symptoms are observed. In some the gums are pale, in others morbidly red, and the alvine evacuations and urine present no unusual appearances.

"Having described the disease, now for the *treatment*, which is chiefly local; and I cannot do better than give a list of the remedies which have been employed by different practitioners, each with some appearance of success. These are poultices, water-dressing, blisters, tincture of iodine, solutions of sulphate of zinc and copper, nitrate of silver, and red precipitate.

"*Ointments*, such as the nitrate of mercury, red precipitate, iodine, creosote, and charred root of the castor-oil plant.

"*Constitutional treatment* has consisted in giving iod. potass., liq. arsenicale, lime-juice, aperients, alteratives, mineral acids and tonics of various sorts, all of which are said to have appeared to do some good for a time.

"In my own experience, I have found that, after the removal of the crust (unless it was an open sore), touching the diseased part, including a small portion of the surrounding sound skin, with potassa fusa, was an excellent plan. On separation of the eschar, a clean-looking sore, secreting good healthy pus, was the result, which filled up readily, contracting from the edges. Such constitutional treatment was adopted as the appearance and state of health of the patient indicated. I have tried nitric acid and the solid nitrate of silver to the entire surface of a sore; but these applications formed hard, smooth, parchment-like crusts, without penetrating deeply into the diseased part, which seems to be necessary to the formation of a healthy sore, and the fresh step in setting up the healing process of the ulcer.

"Next to the potassa fusa, I found the sulphate of zinc in strong solution or fine powder was most efficacious in destroying the diseased surface, and producing a new and healthy sore. I have tried the red precipitate in powder and ointment; it kept the sore clean and healthy-looking, but favoured the formation of the dry parchment-like surface, under cover of which the unhealthy secretion was reformed.

"The solid nitrate of silver appeared to do good when used in touching the line of demarcation; but the hard scale which it formed had to be removed daily by a poultice, otherwise the mischief went on underneath it.

"Notwithstanding all modes of treatment, however they certainly fail in making a thorough cure of the disease which shows itself in the formation of Delhi ulcers, so long as the subject of the disease remains in Delhi. It may become milder—may cease for a time, or appear to wear itself out; but change of air or climate, and that only, effects a complete eradication of it from the system."

ON GLAUCOMA AND THE OPTIC PAPILLA

NEW OPHTHALMOSCOPICAL FACTS; OPTICAL ILLUSION IN EXAMINING THE PAPILLA IN THE INDIRECT METHOD; NORMAL STATE OF THE PAPILLA; DISEASED STATES.

Dr Mackenzie, of Glasgow, says:—I long since established to my own satisfaction the three following conclusions regarding glaucoma:

1st. That the sea-green appearance behind the pupil, whence the name arose, does not depend, as was once generally supposed, on any thickened or discoloured condition of the vitreous humour, but on a diplochromatic state of the crystalline, by which it absorbs the extreme prismatic rays, and reflects the middle ones.

2nd. That the vitreous fluid in glaucoma is superseded by an unhealthy secretion, which over-distends the eye, makes it feel hard, causes severe pain by pressing on the ciliary nerves, and obliterates the sensibility of the retina; a state of matters which I found to be susceptible of relief by paracentesis of the eye, through either the sclerotica or the cornea.

3rd. That in advanced cases, the optic nerve behind the eye shows itself, on dissection, in a state of atrophy, deprived more or less of its proper nervous substance, and flattened.

Ophthalmoscopic investigations have added some new facts to our knowledge of glaucoma. One of these is the pulsation of the arteries of the retina; and another, the concave or excavated state of the papilla of the optic nerve. Neither of these phenomena, however, is peculiar to glaucoma; both of them being occasionally met with in other diseases of the eye. The former of them seems to indicate an increased resistance to the flow of blood in the vessels which supply the retina; the latter may be regarded as the effect of one or other, or of both, of two different causes, namely, the atrophied condition of the optic nerve, and the increased pressure on the internal parietes of the eyeball, from the superabundant secretion which occupies the place of the vitreous humour.

These phenomena can scarcely be discerned in the advanced stages of glaucoma, owing to the diplochromatic and muddy state of the crystalline. To see them, then, the student should be directed to examine a case in which the dioptric media have as yet lost but little of their normal colour and transparency.

To discern the pulsatory movement of the vessels, requires a sharp and experienced eye; and the observer will find it of service, while directing his attention to this point, to have the patient's head supported, and the diseased eye steadied by the fingers of an assistant.

If the indirect or inverted method of ophthalmoscopic observation be selected, an optical deception is apt to bewilder a beginner, as to the condition of the entrance of the optic nerve, a nearly circular spot, though not unfrequently oval, variable in size, but measuring on an average 0·6 line in diameter, and which, although styled

papilla or *colliculus*, is, in its normal state, nearly level with the retina, and even a little depressed in its centre. In the direct method, where the observer regards the illuminated non-inverted fundus oculi through an aperture in a concave mirror, without the aid of any extraneous lens, the great magnifying power of the cornea and humours of the patient's eye gives to the papilla an apparent magnitude larger even than that of the pupil; but in this way it cannot be well seen as a whole, and generally requires the eye of the observer to be brought inconveniently near to that of the patient. Instead, then, of using the patient's eye as a powerful single microscope, in actual contact with the objects on the fundus oculi to be examined, and thus viewing them directly, it is better to obtain a smaller but more defined image, although an inverted and virtual one, of those objects, by converting the patient's eye for the time into the object-glass of a compound microscope, which we do by holding in front of it a thick convex lens. The image which we then see of the several parts of the fundus oculi is an inverted one, like that of an object examined with any ordinary compound microscope; the entrance of the optic nerve is seen towards the temple instead of the nose; the macula lutea appears to the nasal side of the optic nerve instead of the temporal, and a little below the level of the nerve instead of above it; while the principal trunks of the retinal vessels, instead of branching in the direction of the temple to embrace the macula lutea, seem to bend towards the nasal side of the eye. The apparent position, in fact, of all the objects on the fundus, viewed in this way, is the reverse of their real position.

The most important optical deception which arises from viewing the fundus in the indirect method, as well as the most puzzling to a beginner, affects the papilla. The student has probably heard that the papilla, in the glaucomatous eye, is cupped or excavated; but to his view it appears quite the reverse—it appears rounded and prominent.

To comprehend clearly that this is an illusion, all that one requires to do, is to impress with the head of a pin, a small dimple on a bit of paper, and put this under a compound microscope, with the concave side of the impression uppermost. The same appearance will then be seen which is presented by the papilla of the glaucomatous eye, namely, that of a rounded and protuberant surface.

This optical deception arises from the inversion which the image suffers by being viewed through the compound microscope. We judge that an object, viewed with a single eye, is convex or concave, solely by the manner in which light is reflected from the body under examination. The light which falls obliquely on a convex surface illuminates that side which is nearer to the source of light; the side farther from it is in shade. The light which falls obliquely on a concave surface illuminates that side which is farther from the source of light; the side nearer it is in shade. Let the source of light remain in the same position, but invert the image of the object illuminated, so that the light which falls on the farther side of it may seem to fall on the near side, which is the case when we look through the compound microscope at the hollow on a bit of paper, or when we examine the optic papilla through the compound microscope formed for the occasion by the patient's eye *plus* the convex lens held in front of it; and both the dimple on the paper and the papilla, although they are actually cupped or concave, will then appear convex and prominent.

If, on the other hand, we turn the convex side of the dimple on the paper uppermost, and view it with the compound microscope, it appears concave. The inversion of its image causes the light which falls on its near side to appear as if it fell on its farther side, and thus the eye is subjected to a deception the reverse of the former, and from which it cannot free itself. If there be cases, then, in which the end of the optic nerve within the eye actually projects in a convex form, they will offer, when examined in the indirect method, the appearance of a cup or depression.

Such facts have long been familiarly known; the apparent transmutation of an intaglio into a cameo, or that of a cameo into an intaglio, under the compound microscope, being a common source of amusement, fully discussed by Sir David Brewster in his 'Letters on Natural Magic, Letter V.' Important as their bearing is on pathological examinations of the eye, they seem to have escaped the notice of ophthalmoscopists, till attention was directed to the subject by Dr A. Weber, in a paper in the 'Archiv für Ophthalmologie,' Band II, Abtheilung I, Seite 141.

In a highly-interesting communication in the same journal (Band IV, Abtheilung II, Seite 1), Dr H. Müller has directed attention to the normal, as well as to several diseased states, of the optic papilla.

His account of the entrance of the optic nerve into the eye, and the diagram which he gives in illustration, tally remarkably with the thirteenth figure in Mr Bowman's 'Lectures,' and the corresponding explanation. From the statement and figures of these two observers, especially those of Dr Müller, it may be gathered that the lamina cribrosa is normally somewhat concave towards the interior of the eye; that the fibres of the optic nerve, suddenly losing their white substance and dark outline, enter the eye on a level with the chorio capillaris; that at this point the whole nerve, from the change which its fibres have just undergone, is considerably and rather suddenly reduced in thickness; that the fibres, bending more or less abruptly outwards, and spreading around, become clothed by the exterior or radially-disposed layers of the retina; that the edge of the opening through which the nerve passes into the eye, as well as the fibres themselves as they traverse that edge, form a slight elevation or approach to a papilla, leaving in the situation where the trunks of the central vessels of the retina generally make their appearance, a small foveola.

Dr Müller points out the difficulties which attend the anatomical examination of this depression, arising from the softness of the part, and its liability to change on being touched; and shows how these difficulties may best be obviated. He directs attention to the varieties which exist in different individuals; varieties in the depth of the depression, from 0·2 to 0·5 millimetre; varieties in its form and position, for it is not always symmetrical, and does not always correspond to the middle of the nerve, but is sometimes considerably nearer to the macula lutea, or has one portion of its edge more raised than the rest; varieties in the disposition of the vessels, for while the large trunks generally emerge from the middle of the foveola, one or more sometimes seek a passage for themselves close to the edge of the chorio capillaris, so as to make their appearance by the side of the nerve; facts, all of which should be carefully borne in mind by ophthalmoscopists.

In regard to abnormal prominence of the papilla, Dr Müller shows that this is likely to arise from an atrophied state of the exterior layers of the retina, a thickened condition of the primitive nervous fibres, as well as infiltration of the nerve by blood, inflammatory exudation, or new formations. He relates a case in which a concretion in the site of the lamina cribrosa caused a protuberance of the papilla. The very earliest stage of encephaloid tumour should show an abnormal prominence of the papilla.

On the other hand, intra-ocular pressure, and atrophy of the nerve, existing either singly or in combination, are the causes of abnormal excavation of the papilla. In cases of intra-ocular pressure, either simple or combined with atrophy of the nerve, paracentesis, either corneal or sclerotical, is likely to produce a change in the depth of the excavation, sufficient to be recognised on ophthalmoscopical examination.

Morbid excavation of the papilla varies in depth, reaching in extreme cases to a millimetre beyond the level of the choroid. In such cases, the sides of the excavation are nearly perpendicular, or are even concave, and its edge, of course, impendent, so as partially, or even completely, to hide from view the course of the vessels as they pass from the bottom of the excavation and over its edge to the retina. In slight cases, the sides of the excavation are convex, and its form that of a funnel. The lamina cribrosa, under such circumstances, keeps its place; but in more advanced stages, it is pushed back, and the excavation is much extended laterally. Such extreme cases of expansion are not the result of uncombined atrophy of the nerve, but must arise from the supporting resistance of the parts being weakened by previous inflammation, whence they come to yield more readily to intra-ocular pressure.—'Ophthalmic Hospital Reports,' No. xi.

RODENT ULCER.

A "gentleman had a cancerous ulcer for five-and-twenty years, at the end of which time the whole side of the face and forehead, the eyelids, nose, and ear had become involved in superficial ulceration at one period or other; but in one part, on the cheek, a tumour of the size of an egg had grown, and had been removed by the knife five years before I saw him, and had again formed, and had been excised a year afterwards; after which time this portion of the surface, like the rest, presented the usual appearance of the superficial ulcer. Notwithstanding its extent, and the length of time it had lasted, the disease had not in the least affected the general health, and only some parts were painful, and that chiefly from exposure to the air in dressing."—Mr Cæsar Hawkins.

The following is an abstract of the next case adduced by Mr Hawkins: — Riley, aged sixty-one, admitted February 24th (1841?). A small tubercle had formed immediately below the inner angle of the right eye two years and a half before. It was not painful. It ulcerated, but healed again for a short time, but broke out again twelve months before admission. It then implicated the inner part of both lids, had destroyed a good deal of the external part of the eye, causing collapse of the globe, and extended deep into the orbit. It also extended over the bridge of the nose, a little to the other side. It subsequently perforated the floor of the orbit, so that a probe passed into the antrum. Caustics (the acid nitrate of mercury and the chloride of zinc) were used, and with great benefit, but no hope of complete cure was entertained. With exception of some tremulousness of the right hand, he looked in good health. The glands were not enlarged.

Edward C., aged fifty, has had rodent ulcer of the eyelids for seven years past. It began on the right lower eyelid, and has progressed very slowly. He has been under Mr Dixon's care, on and off, for five years. The disease has now involved the whole of the lower lid, and extends to both canthi: the middle of the upper lid is sound. At the angles the rounded raised hardened border is very characteristic. There is no warty growth, and the surface of the sore is covered by a thin scab. The globe is collapsed and shrunken. He states that he could see well until about six months ago. He is a fairly healthy-looking man of dark complexion, and states that he is quite as well now as ever he was. He has scars of suppurated glands under the jaw, but they were from strumous disease long ago: one of these is still a little enlarged, but it is from the same cause. There is no family history of cancerous disease. It began as a small pimple, and lasted as such about two years before ulceration took place.

M. S., aged fifty-five, was admitted under Dr Humphry's care, on February 26th, 1857, into the Cambridge Hospital, with an excavated ulcer having an indurated base, extending over the lachrymal sac, and upon the side of the nose. It was adherent to the bone. She stated that it had first commenced about two years before, and that it had never been painful. She had no enlarged glands. She was in good general health. A few days after her admission Dr Humphry excised the ulcer, removing with it the orbital edge of the superior maxilla which was involved in the base of the sore. All the morbid structure was carefully cleared away. In October, 1858, Mrs S. again applied for admission on account of a return of her disease in the form of a small knotty growth, closely adherent to the bone. She still had no trace of enlargement of the lymphatics. A second very free excision of the diseased part was performed. The wound healed well, and hitherto (nearly two years) the cicatrix remains healthy.

Robert M., aged forty-six, was admitted into the Hull Infirmary on September 30th, 1859. He suffered from an indurated ulcer on the left cheek, close to the lower eyelid. It was the size of a shilling, and had warty edges. The disease had existed five years, and had been repeatedly, with temporary benefit, treated by escharotics. A free excision was now performed, after which the part healed well. The duration of the disease in the above case, its slow advance, and its location, justify the opinion that it was rodent, and not truly cancerous.—'Medical Times.'

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

THE MEDICAL CIRCULAR.

WEDNESDAY, SEPTEMBER 26, 1860.

THE COMING SESSION.

It is expedient, on the approach of a new Session, that we should address a few words of counsel to our junior brethren. They are commencing a career full of responsibility, without any experience to guide them, or much foresight to enable them to elude dangers. The sanctities of home will no longer exert their chastening influence over the desires, and the unsleeping eye of paternal love will no longer anticipate the covert evil, and conduct the unwary foot away from the snare. Alone will the youth be amid the temptations of a Metropolis filled with all the appliances of pleasure and incentives to vice. Our great city is a painted Jezebel, gay to look upon, but full of wiles within. Not, indeed, that it is altogether corrupt, that it has not many a centre of radiating benevolence, many a sweet spot where Virtue blossoms beauteously in the sunlight of truth and honour, and the hard daily life of men is wrapped round with a fragrant atmosphere of moral loveliness. But these chancels of the heart are not free to every foot. Most of you must stand without the screen, and not even see the delightsome splendours which, you may have been told, shine within the sanctuary.

To most of you, London will show only her parti-coloured outside—the glare of her gaslights, the profanity of her shades, the bustle of fron streets, and the loneliness of the moral nated where the poor do congregate. Cities, nitrates.

the followi exhibit outwardly to the spectator

"1st.—Altho nes of character. There is a water of the wells o to believe that it must what makes her hide herself salts as are known to be i water peculiar to Mooltan, and She closets herself where a very similar ulcerative ays answer to the prevail.

"2nd.—The disease is more prevale, he is prone to May not this be ascribed to the rai world may supplies these wells, in percolating thro taking with it large quantities of the salts misertion, and thereby causing an excess in the of salts already in the wells, and consequent ll the to those who drink or otherwise use the water now nally?

"3rd.—May not the fact of the disease being the prevalent in the dry weather at the beginning of t hot season, and before the rains, be due to the wa e in the wells being less scanty from daily use, a h not being renewed by a supply of rain-water, a consequently less salts being held in solution in th water which remains? It follows, therefore, t he these salts, whatever they may be, when constan taken into the system, undergo chemical chan it,

smelling of poppy, mandragora, and other deadly things.

There are too many young men, we fear, who fall into the traps set for them in our Metropolitan hiding-holes. We will not flatter our young friends too much by extolling their virtues, their industry and good conduct, as is now a very prevailing fashion among their teachers. As a class, they are undoubtedly much improved in all laudable ambitions; but there are exceptions enough still to make us wish that their unfledged moral vigour was placed under happier circumstances for its development. We are sure that most Practitioners who have had opportunities of observing the habits of young men after they have left College, must know, as well as we, that very many have contracted propensities during their Metropolitan career which deprive them of their usefulness, and degrade their character.

The Nestor of our Profession, Sir Benjamin Brodie, has lately, in a most conspicuous manner, endeavoured to convince young men of the mischief resulting from one practice in which they are prone to indulge—that of smoking. We cannot do better than enforce his teachings. The most favourable sentence that can be pronounced upon this practice is, that it is a mere invention for the dissipation of thought. Beyond this, it seduces the young man into habits of idleness; it leads him into frivolous society; it brings him acquainted with the pewter pot, the casino, and the billiard-room. How hard a thing is study surrounded by all these enticements! How difficult it is to buckle down to study in the third year, if the habit have been neglected during the two first!

Why is it that the Student finds his physiology so difficult, and his decompositions so incomprehensible; why does he get so muddled over his Latin, and feel his head splitting with the effort to cram it with the distribution of the nerves, and the minute anatomy of the spinal cord? He has simply neglected his opportunities, he has never acquired the *habit* of study. He has dissected without observing, listened without remembering; with the scalpel in his hand, he has been thinking of the incidents of the last night's comedy at the Olympic, and whilst sitting at lecture has been essaying to reproduce the pantomime of Robson in his last new character. Tell us, you young man in your second year, if this be not true; and you, Student, now grinding for your examination, confess to us if the difficulty you now experience does not arise from dilatory, thoughtless habits in previous years, of which the description now given is a fair type?

We conjure you to cultivate habits of industry. You will be obliged to work hard enough by-and-by, if you be destined to hold a fair position in society; then begin now, for you cannot begin too soon. On your escutcheon of gentleman must be written "Labour." He who has not acquired the art of work will be cast by an irrevocable doom among the pariahs of his profession; but it is consolatory to know that every man carries his fate in his own hand. There is a law over us, but there is also a law within us. It is not in our stars that we are underlings. Periander, one of the Seven Wise Men of Greece, gave it as his sagest speech, that "nothing was impossible to the industrious." Indeed, to the industrious man all things are possible that prudence approves. Even character is subjugated by industry, and made conformable to this habit.

Some of you have come to town with limited resources, and have received with every guinea an injunction to husband the loving liberality which cannot be often repeated. You cannot add cruelty to sacrifice by squandering in idle pleasures either the time or the advantages thus so dearly purchased. Why should we not touch upon this topic, domestic though it be, and out of our ordinary province? We allude to it, because we know that many of you are the sons of Medical men, and because we feel a common sympathy with everything that touches the hearts or interests of our brethren. We are glad to know that at several Hospitals, the appointments of House-Surgeon, Dresser, and Clinical Clerk, with various scholarships and prizes, are open, without payment, to the most competent students of the School. These are noble and valuable opportunities, which we trust you will not neglect. By studying for these appointments, you will rapidly improve yourselves; and by gaining them, you will render some return for that liberality which makes you a debtor to your family. Before the youth enters to the classes, let him look over the prospectuses, and choose that School which, possessing at the same time other advantages, offers the most numerous opportunities for the reward of his industry.

Few words suffice to animate the youth who has a gift of goodness and an aptitude for manly work; volumes would be lost on him whose eyes are bent backwards, looking ever towards the flesh-pots of low desires. We will not, therefore, occupy more time with these topics. We would simply say,—Avoid dissipation! It is the golden sea on which many a fair barque has suffered shipwreck. It is inconsistent with true self-respect, and with the esteem of all men whose good word is an honourable possession. It is well to start in life with one good man's praise; it is a testimonial that will accompany you in every step of your progress; and once having it, you will endeavour to deserve it. We have known, and still know, many men who have won honourable positions in life simply because they started with the testifying praise and kindly help of some generous spirit whose esteem they had won by their own industry and loyalty of soul. That which is in youth

an impulse, in age becomes philosophy; but it is ever true, and experience proves it. Let the young man receive it as such, and resolve to begin his career as every honest and wise man would like to finish one. G. R.

SUMMARY OF THE WEEK.

LUNACY LEGISLATION.

For the last twenty years, legislation for the proper care and custody of lunatics has been going on. The machinery it has called into action has been extensive, and sufficiently strict to carry out any supervision with vigilance. Thus, legislation has been directed to the amelioration of the condition and improvement of the treatment of lunatics in Private and Pauper Asylums. What is called the *non-restraint* system has become fully established. Much has been made of this system as a marketable commodity amongst its first advocates. These are considered and must be termed the *puritans* of that sect. We fear much deceit and great evils still lurk under the cloak called *non-restraint*. We fear it is a system which reqnires as much suspicious *surveillance* as do the patients who are under its tutelage. This is somewhat apparent from the evidence given upon the Colney Hatch trial at the Central Criminal Court, a full report of which we give in another part of this number. Although we have spoken of *non-restraint* as a system fully established, its merits passed a severe ordeal from the evidence directed during this trial. In the case of Private Lunatic Asylums, legislation has had much difficulty to contend against, from their commercial character, and from the private capital invested in them inducing reluctance to interfere as little as possible. Investments of private capital are called "invested rights," and in this country have always been scrupulously regarded and held sacred. But this kind of investment differs from all usual commercial speculations, being dependent for its prosperity upon the insanity of its customers. This has constituted the main difficulty with which legislation has had to contend, and has hitherto rendered its efforts, if not abortive and futile, at any rate very unsatisfactory. So much has this been the case, that the fact of the investment of private capital having had a tendency to involve the safety and invade the sanctity of social rights was long lost sight of and disregarded. Even now, *any one* may offer himself as a custodian of the persons of lunatics who can comply with forms and regulations which give him the privilege to have a licence for that purpose conferred upon his house. The house thus licensed, henceforth becomes subject to inquisitorial visits—the *surveillance* of Visitors and Commissioners, who enforce strict regulations. We consider it would be an improvement of this system if, in addition to the usual trading licence required for the house which undertakes the reception and custody of lunatics, it should be required that every such house should have attached to it a Medical man, who, in addition to his customary qualifications, should be required to have passed an examination before a Special Board of Examiners for that purpose: such examination to be free from all charge, and should confer upon approved candidates an exclusive licence to practise in this department of the Profession, in licensed houses and in Pauper Lunatic Asylums; the candidates to be limited to men whose qualifications include certain specified diplomas or licences which have been obtained at Boards of Examination of Colleges and Universities. By thus securing a high order of Medical education and training, you restrict the practice to men in whom the highest confidence may be placed. Institutions thus organised and superintended would be elevated in the estimation of the public. Laws made for felons and misdemeanants would have no application, and would no longer be suspended over the heads of superintendents, casting discredit and wrongful aspersion over a Profession totally undeserving such treatment. The Act of the Legislature passed during the late Session is, if anything, more insulting to the Medical Profession than any which has preceded. Instead of aiming to degrade the Medical Profession, the object should be to elevate its *status*, and to draw a distinct line between it and the commercial investment, clearly defining its duties and position. To mingle highly-educated Medical Officers in the same category with nurses, matrons, servants, and other persons employed in an Asylum, if it was not absurd and ridiculous, would be grossly insulting. The clause to which we refer runs thus: "Any superintendent, officer, nurse, or other person employed in an Asylum, who *strikes*, *wounds*, or *ill-treats*, *&c. &c.*, any person confined therein, is to be guilty of a misdemeanour, and on conviction *liable to fine and imprisonment*, or to forfeit for every such offence, on a summary conviction, a sum not exceeding 20*l.* nor less than 2*l.*" This clause is rendered the more odious by being exclusively levelled against English Medical Practitioners. No such clause is enacted in the Bill passed for the regulation of Asylums in Ireland. It is also rendered more degrading, since the common law is already armed with powers to punish such delinquencies. A still further and more severe punishment awaits such a social outrage committed by legal Medical men: the delinquent would have his name erased from the Register, according to Clause XXIX. of the New Medical Act of 1858. Above all, public opinion would denounce him.

LITHOTOMY.

We are convinced that the median operation for Lithotomy, as performed by Mr Allarton, and lately practised at the Westminster Hospital by Mr Barnard Holt, with dilatation of the prostate gland and the neck of the bladder, must always be a tedious and troublesome operation. We believe it to be also attended with complications and accidents which may be considered *non expertus* in the present day; and that it would be also difficult without the intervention of narcotism to perform this median operation. Any operation whose plan includes avoidable delay or possible hindrance is unacceptable to Surgeons of the present day. The recommendation in favour of the median lithotomy is the smallness of the section, especially of the external incision; that the prostate, instead of being cut, is either split or dilated; that the neck of the bladder is less injured than in the lateral operation; and that urinary infiltration is thereby avoided. We will not pause to compare the merits of bruised and incised wounds; nor to contemplate the possible, but (as the lateral operation is now performed by good Surgeons) the very remote, danger of urinary infiltration; nor to inquire into the danger occurring by forcible dilatation inducing inflammation and gangrene of the mucous membrane of the bladder, which, no doubt, was the fatal termination in Mr Holt's second case of last week, as reported by him in the 'Lancet.' Mr Holt speaks of this injury as a lesion not greater than is usually inflicted by the lateral operation. This may be true as to extent, but entirely illusory as to the character of the injury, since one is a clean cut, the other a bruised and lacerated wound. In short, the operations are so widely different, that they offer few points of comparison. The median operation must be limited exclusively to spare, and, we think, to young subjects. Certain operations have a more mechanical procedure than others, and admit of little extemporaneous discretion during performance. Such may be considered the flap operations; Wood's and Wütz er's for hernia; Pirogoff's for amputation of the foot, which is a nice sample of carpentry and joinery; resections of joints; the gorget operation for stone; and also the median operation. The latter is, as in the case of the gorget, a gauged operation. The median is governed by a certain triangular form of knife — leverage being effected by the finger of the left hand, wedged between a director below and staff above, by which means to effect rupture or dilatation of the urethra and prostate (Mr Partridge and others use the blunt gorget). Should this gauge be incorrectly measured, by the triangular knife being either too large or too small, complications must occur; especially since, being effected by a backhanded *coup*, the introduction of any other knife would not be desirable, or perhaps would be awkward, to enlarge either the internal or external incision. The objects aimed to be accomplished by the median

operation, we suppose, are: 1st. To avoid wounding by incision the prostate and neck of the bladder; 2nd. To effect dilatation of these parts, instead of cutting them; and, 3rd. To wound few tissues, and make a small external and internal section; by which means cicatrization is quickly effected, and little mischief done. The object of the lateral operation is nearly opposite to the median in many respects. By so cutting laterally, it obtains more space, a larger external and a free internal section, the axis of the latter corresponding with the former, which is made so dependent as to be nearly parallel to the erect position of the body. Thus the two operations propose opposite aims, (Mr Holt's cases are not very favourable —one death in three operations,) and upon their success and merits must they stand. The backhanded section through the raphe of the perineum into the urethra, carried along the groove of the staff anterior to the prostate—the relative position of which is ascertained by the finger being introduced into the rectum—is necessarily small, which is considered its virtue. This small external opening must require some time and some force to be exerted in retracting the forceps charged with a stone between its blades, which cannot be practised without injuring in its progress, and bruising the tissues. We were rather pathologically puzzled with Mr Barnard Holt's *dogma*, of *rigor* being an idiopathic disease. We have always comprehended rigor to be accepted universally as a *symptom* of either local inflammation and irritation, or a *symptom* of the access of suppuration, gangrene, or as a consequence of inflammation. The median cannot be considered a new operation, since it was performed many years since by Dupuytren. We should observe *en passant*, that Mr Holt does not name the time occupied in the performance of the operations. The sudden death to the patient operated upon in his second case, which occurred the following day, is inexplicable, supposing the patient to be in a fit state for the operation to have been done. Tissues and prostate may be dilatable in children, where room moreover is scarce; but in adults, where you have plenty of room for the knife, you, on the other hand, obtain rigid fibres and less elastic tissues. Median advocates say, cut a line or two in rectum. The operation, now on its probation, is a resuscitated novelty, which we think will become again shelved.

SEASONS AND CEREALS.

The ambitious man always seeks agrarian fame and distinction. The soldier of fortune begins his career by a limited sense or anticipation of its enjoyment. Some forlorn hope or honour reaped with life, and irrigated with blood on the battle-field, may stop short his ambitious yearnings. Cincinnatus was found by the Senators, when Rome was in danger, at the plough-tail. The Senate conferred upon him the authority of Dictator, to repel the the Æqui and Volsci, which having done, he relinquished the Dictatorship to return and plough his lands. The veteran lawyer leaves, perhaps, the woolsack, to enjoy the reality of breeding, growing sheep, and shearing wool—to fatten the sleek kid and tender doe. So with the fortunate physician: if he has enjoyed the favours of Court and nobility—been patronised by beaus and dowagers—he has, perhaps, accumulated fees, and spreads his gold broadcast over dirty acres. Our worthy contemporary of the 'Lancet' is winning fresh laurels. Not satisfied with triumphs hardly earned and justly meted to editorial talent and distinction, in his case awarded more especially as having been the ounder and mainstay of that distinguished periodical, he also early achieved legislative honours, and has worn them with becoming and prudent dignity. Enjoying the *otium cum dignitate* in his Idyllian retirement, he now finds leisure to practise agrarian arts, and to study the bucolic muse. Thus will the Esculapian column be decorated with the ears of Ceres, as of old was the Corinthian capital with the acanthus leaf. He may, with equal grace, hold inquiry upon injuries sustained by the inclemency of the seasons, as from injury sustained by steel or lethal weapon—by fire, water, or poison. Utilitarianism has so usurped the agrarian domain, that all who urge and propagate its teachings are eagerly regarded. Science, physical, organic, and mechanical, has freely made oblations at the shrine of Ceres, instead of propitiating her in Idyllian or Orphean strains, and has wooed and won her favour with more success. This extraordinary season of cold, sunless, inclement weather may well provoke inquiry and stimulate invention to endeavour to mitigate impending yet preventable mischief. Our worthy contemporary, with this praiseworthy object, has drawn upon his resources of experience and fancy. Apprehension, amounting almost to tribulation, prevails, lest the housing and ripening of our cereals should fail. Our stormy, fickle climate always gives cause for excitement and apprehension on this score. Under such unusual circumstances and conditions, it is true patriotism to contribute in any way to alleviate the evil and attempt to mitigate alarm. This climate of ours, nevertheless, is a most propitious one for the growth of cereals; our soils being also equally fertile and reproductive. Its variability and changeableness rather contribute than not to this result, as we have witnessed during this fickle and trying year, our crops having, perhaps, suffered less than those of any in Europe. This glorious *triticum æstivum*, or *hybernum*—hardy, enduring, nourishing—is like the natives of the island; it flourishes and propagates in every clime, and constitutes the main nourishment of our Saxon race. Wherever an Englishman dwells, wheat grows. It is affected but little by cold or by heat, by wet or by drought; but, equally with the Saxon, grows, matures, and ripens by sun and moisture. This is proved in respect of the low ruling temperature of this summer having suited the constitutions of the people, health having prevailed. Except in wet, cold, heavy clay soils, the wheat-crops are good. Ague has been rather more prevalent than usual. This occult symptom always indicates something more than seen, both amongst socials and amongst cereals—something wrong in the constitutional system of the one, and in the constitution of the soils of the other. Our wonderful inventive faculty to bring the best physical and mechanical aids to stimulate production and to diminish labour, to force crops, and to economise both the period of their growth, and of their hybernation in the matrix from which this growth is the issue, is justly the admiration of the world. An amateur (so-called *gentleman-farmer*) writes a letter to an eminent machinist, telling how easily he might improve a reaping-machine. He urges, that by adding additional apparatus to it, easily arranged, in the form of cutting-knives, at a higher elevation, his reaping-machine might be made to cut the ears from the straw, as well as the straw from the stubble. The machinist replies, "I have spent so much money upon this invention, I can't afford to spend more in trying fresh experiments." Fortunately, this is not required. It is a necessity demanded of man's labour and invention, to sow and to reap. If this be done well, successfully, and economically, more is not required of him. Almost any expenditure to accomplish this object is compensated to him for his skill, enterprize, and industry. In the instance of wheat and other cereals, if they sprout, the mischief has occurred before cutting has commenced. If they be cut before sprout has taken place, the source of growth becomes stopped, and vitality and vegetation cease in consequence, if the corn be treated with common care. If it be properly ricked, or stacked upon elevated wheat hovels, the sharp equinoctial gales of September and October soon dry, by their searching breeze, every ear, and every corn, without incurring further cost or expense. The sheaves are artistically stacked over and above each other, best to encourage rapid draught and ventilation. The best mode of drift may be effected without artificial heat for this purpose, which would tend to induce sprout. We think Mr Wakley's ingenuity has been thrown away on this occasion. Mechanical invention and artificial heat, to transmit a rapid circulation of air for such purposes, are unnecessary, and an expense that could not be incurred. Nature, which grows and ripens the cereal without aid, would also repudiate the necessity of such costly machinery to dry and render its condition good. For sowing, reaping, and improving soils, we ungrudgingly give our costly outlay in any machinery required, or which would expedite those processes. For the purpose of drying cereals, housed or stacked, such expenditure is fortunately unnecessary, and, moreover, is impracticable.

SKETCHES OF EMINENT PHYSICIANS AND SURGEONS OF THE LAST CENTURY.

By JOSHUA BURGESS, M.D.

MEMOIR OF JOHN HUNTER, F.R.S.

(Continued from page 197.)

Notwithstanding he was so illiterate as to receive from Jesse Foot and others gibes on that account, on the other hand Dr Crichton charged him with plagiarism. Opinions which had been dormant 2,000 years, and overlooked by profound scholars, John Hunter arrived at by observation of nature. It is true, they had been accurately remarked by the ancients and recorded by them—destined, nevertheless, to sleep in oblivion until revived by the penetrating inquiries and investigations of nature made by John Hunter.

In reference to the painful feuds of the brothers, no doubt the wealth of William and the poverty of John emboldened the first to take such extraordinary liberties. Moreover, Dr William had early and late conferred liberal patronage upon John. At length the latter rebelled in the manner we have described. This occurred five years after William had published the splendid work on the 'Gravid Uterus.' The Royal Society judiciously suppressed publication of these papers and correspondences, although they are retained in its archives. It thus manifested its sense of this painful affair, and consideration for the fame of

the brothers, without giving scandal. Sir William Jardine, in his Memoirs of John Hunter in the 'Naturalist's Library,' says, "Dr Hunter appropriated to himself the merits of a physical discovery, and the physiological views thence derivable, all of which were properly due to his brother. The property at Long Calderwood, and also the lands of Kilbride, were bequeathed away from John, by William Hunter, to his nephew, Dr Matthew Baillie, as before reverted to.

Some years earlier, John Hunter, in conjunction with Dr George Fordyce and an eminent mechanic of the name of Cumming, used to meet, after adjournment of the meetings of the Royal Society, at a coffee-house, to discuss subjects which had occupied the transactions of the Royal Society. This plan ultimately met with great encouragement, and was speedily joined by Sir Joseph Banks, Dr Solander, Dr Maskelyne, Sir George Shuckburgh, Mr Watt of Birmingham, and several others. At these meetings, discoveries and improvements in different branches of philosophy were criticised and discussed before they were given to the public.

About this time he published the second part of his treatise on the Teeth. He read six Croonian Lectures before the Royal Society from 1776 to 1782 inclusive. These lectures treated upon the powers and actions of muscles, and the stimuli by which they are affected; also upon the moving powers of plants. They were not published in the Transactions of the Royal Society; he considered them inconclusive, and more as materials. John Hunter was always reluctant to publish anything he thought unfinished, imperfect, or incomplete. In 1780 he read a lecture upon the muscular action of bloodvessels, which was not published until his 'Observations on the Blood and Inflammation' were arranged. His contributions about this time became too numerous to recapitulate; including the 'Anatomy of the Organ of Hearing in Fishes;' on the 'Structure and Economy of Whales,' and on the 'Canine Species'—namely, the wolf, jackal, and dog. These papers, with others, appeared afterwards in 1786 in his work published on 'Animal Economy.' For these manifestations of industry, in 1787 the Royal Society conferred upon him its Copleyan Medal. His zeal in the prosecution of these inquiries was such, that, desirous to obtain accurate information of the natural history of the whale, he "engaged a surgeon, at considerable expense, to make a voyage to Greenland," furnished with every requisite for examining and preserving the most interesting parts, and with proper instructions. John Hunter said, "The only return I received was a piece of whale's skin, with some animals sticking to it." His investigations of the whale tribe were nevertheless very satisfactory, and the paper was accompanied with drawings. This treatise is much prized even at this time. Honours now became thickly conferred upon the subject of our memoir. In 1783 he was chosen Fellow of the Royal Society of Medicine and of the Royal Academy of Surgery at Paris; again, Fellow of the Royal Society of Science at Gottenburgh, and of the American Philosophical Society.

The lease of his house in Jermyn street having terminated, he was harassed with the difficulty of obtaining an eligible residence for the reception of his collection of objects of natural history for his museum. At length he purchased the lease of a large house, and expended upon it 3,000*l.*, on the east side of Leicester square, which proved an unfortunate speculation. Being so much occupied in professional and other engagements, he too hastily concluded this bargain, anxious to escape from the embarrassment and difficulty of obtaining a house, and thus sacrificed the interests of his family. Sir Joseph Banks contributed largely to his museum. This collection was received in a room of extensive dimensions, 52 ft. by 28 ft., excellently adapted, having a gallery extending all round it, and being lighted from the top. Sir Joseph Banks divided between John Hunter and the British Museum all he had collected in his voyage round the world, including many curious specimens and animals. This was an act of friendship, with others of a similar kind which he received from the Hon. Charles Greville and Mr Walshe, for which John Hunter was under the greatest obligations. These manifestations of esteem and public confidence now began to tell by the increase of his private practice. As he stood alone in this pursuit of natural history, he had the refusal of every curious or new animal if for sale, and all were shown and many presented to him. His scope for practice now afforded him many opportunities of distinguishing himself, and he performed several bold operations. In 1781 Captain Donellan's trial at Warwick excited great attention and interest. Donellan was brother-in-law to Theodosius Boughton, to whom he administered a draught containing rhubarb and jalap. In half an hour afterwards Sir Theodosius was seized with convulsions, and died. From the remains of the draught smelling of bitter almonds, suspicion of its having been mixed with laurel-water were entertained. The *post-mortem* was not satisfactorily conducted, and no examination of brain or intestines made, and putrefaction was far advanced. The symptoms were of that nature, that they might have been produced by apoplexy or epilepsy. Although the circumstances were suspicious, these suspicions received no support from *post-mortem* examination, and the circumstances were consequently not linked well together to make them conclusive or satisfactory. John Hunter was too cautious to suit the temperament of Judge Buller. He saw numerous difficulties to prevent arriving at a decided opinion, and would not say more than he could maintain. Judge Buller lost his temper at John Hunter's caution, and attributing no weight whatever to his doubts, made sarcastic remarks at the hesitation he displayed, and the difficulties he suggested. The Professor of Physic of Oxford, who gave evidence on the trial, entertained no such scruples—gave very decided opinions against the defendant, who, with judge and professor against him, and strong local prejudices, was convicted and hanged. John Hunter was equally cautious when examined on the trial of Major Cosmo Gordon, at the Old Bailey, for the murder of Captain Prescott in a duel. John Hunter, in examination by counsel, was asked "if he did not at first sight consider the wound was 'mortal'!" He replied, "there was nothing necessarily mortal in the wound, but the general effects on the whole system were sufficient to show that the patient could not live." The counsel showed great prudence in his subsequent question. "You have no doubt, sir, that the ball was the occasion of Captain Prescott's death?" Answer: "None whatever."

Hunter was hospitably disposed, and what time he could steal from his pursuits was devoted to society. As his income improved, he lived in a liberal style—gave dinner-parties, and of a Sunday evening received his medical friends. He kept a carriage and footman for Mrs Hunter, and enlarged and decorated his residence at Earl's Court. At this residence he spent much time, recreating himself amongst the numerous natural objects he had collected. His health had not been thoroughly established since his attack of illness in 1785, and this break in his engagements tended to alleviate his symptoms. His heart became affected upon agitation or sudden exertion, which prevented his visiting patients at night or on quick emergencies, or performing operations without assistance. The account which he gave of this illness, which, no doubt, was connected with organic disturbance of the function of the heart, was of a most extraordinary kind. He stated that the pulse ceased, and, in short, that the action of the heart ceased, for full half an hour. The respiration was not interrupted, although it continued to act very slowly. He could walk about, but became pale as death. The function of the heart at length returned upon administration of cordials and stimulants. A visit to Bath recruited his health, and in a short time he became convalescent. In consequence, his brother-in-law, Everard Home, who had now retired from the army, attended and assisted John Hunter in his practice until within a year of his death. This afforded Home opportunities, which confidence he afterwards so much abused.

The Queen presented him with a small bull, with which he frequently amused himself by playing and wrestling. On one occasion the bull got him down, and he was in great danger, but was rescued by his servants. These recreations indicated the simplicity and playfulness of his character. He introduced his operation for the cure of aneurism about this time. It was a decided discovery of an important surgical operation, and physiological fact, by which he proved that the circulation could be carried on in a limb by anastomosis. This tying of the artery at a distance from the aneurismal tumour, between it and the heart, was then considered to be a "famous operation." It supplanted the old, time-honoured operation of laying open and emptying the aneurismal sac, which frequently failed. The French surgeons laid claim to a previous discovery, and much jealousy was excited; but neither Guillemeau, Anel, nor Desault practised this operation, or anything similar, with any notion that anastomosis would be carried on, or would prove sufficient for the nutrition of the limb. As in the case of other discoveries, one determined one stage, and another a further improvement. The French surgeons never followed Anel's plan, who was the first who had some confused notions upon the operation, and for seventy-five years no further notice was taken of it, or operation performed, until John Hunter's celebrated operation for popliteal aneurism, securing the femoral artery anterior to and not interfering with the tumour in the popliteal region, which was a decided surgical discovery and improvement upon previous practice. No doubt that all *discoveries* are governed by a similar accident and chain of events. Desault, notwithstanding, went on practising in the old way. No doubt, John Hunter's new operation for aneurism laid down correct and important principles in surgery.

In 1786 he was appointed Deputy Surgeon-General to the Army, on the death of Mr Middleton. He now published his work on the 'Venereal Disease.' It had been long looked for, and had a rapid sale. It was the first of his works printed and published by the booksellers, having always previously printed his own works. He gave himself great attention in compiling this work. Previous to publication it was submitted to a committee of his friends, including Sir Gilbert Blane, Drs Fordyce, Pitcairn, and Marshall. This work upon the venereal disease is not superseded in the present day, and still remains the best general treatise upon the subject. His dogmas held full and uninvaded sway for a long period, and have only recently been at all successfully disputed. He considered the test of syphilis to be its curability by mercury. Ricord, and many others, have agreed with John Hunter's doctrines. But the opinions of the day seem to be in a state of transition. Mr Acton, and, we believe, others, consider the test of syphilis to depend upon its capability of communication by inoculation. They consider that the soft chancre communicates syphilis, the indurated chancre producing only secondary disease, and that the latter is not curable by mercury, or communicable by inoculation.

In 1783 Percival Pott died. Notwithstanding the numerous enemies and envious competitors of John Hunter, he was now hailed with acclamation as head of the Profession. A strong *esprit de corps* was manifested on the occasion, and his elevation seemed a poetical justice fulfilled at its due and proper time. Pott was an eminent man, but rather the slave of routine. That mental and moral discipline, the want of which was the fault of John Hunter's character, had prevailed in Percival Pott so far as to destroy independence of thought and inquiry, which prevailed strongly in the principles of the former. Pott was a complete contrast to John Hunter; gentlemanly in manners and deportment, well read, full of anecdote, and a man of quick discernment, and of keen and polished remarks: London born and bred, love of natural history was not in him, and he had no faith in the stability of Hunter's speculations. Both were social and fond of company; one in a refined, the other in a more robust and genial manner. Pott was a great operator; John Hunter was not—did not like operations, and felt something like contempt for those that excelled in what he termed the art of mutilation. Charlatans and quacks then, as now, were in great vogue, especially for diseases of the eye and rectum, &c. The Taylors, of Whitworth, were at that day in celebrity for diseases of the rectum, as they are in the present for successful treatment of fractures and dislocations. Thurlow, Bishop of Durham, and brother of Lord Chancellor Thurlow, laboured under stricture of the rectum, and was promised little relief from the Profession. The Chancellor called in Taylor to his brother, and several Medical men met him in consultation. John Hunter came late, and Taylor was solicited to examine the patient; to which bluntly refusing, he said "he would do

nothing till Jack Hunter came, for he had no opinion of any but him." Hunter arrived, and Taylor made his examination, and passed up a candle smeared with an ointment, declaring it to be a bad case. Hunter took up the box, and asked "what the ointment was made of?" "That, said Taylor, turning to the Chancellor, "is not a fair question. No, Jack; I'll send you as much as you please, but I won't tell you what it is made of." The paper which John Hunter communicated about this time to the Medical and Chirurgical Society, on 'Inflammation of Veins,' attracted little attention. This subject has been since treated by Abernethy, and also, in 1815, by Mr Hodgson, late of Birmingham, now in London. But more recently, both in this country and France, several eminent men have written upon this subject; namely, in this country, Carmichael, Guthrie, Travers, Arnott, and Lee; and Bouillaud, Velpeau, and Ribes, in France.

In a letter addressed to Jenner, who had broken the thermometer which Hunter had sent him, he says—"You are very sly: you ask for another thermometer; I will send one, but take care those d——d clumsy fingers don't break it also." This was his familiar and somewhat coarse style of address, of which innumerable instances are on record.

OUR NOTE BOOK.

MALFORMATION OF THE CHEST.

Dr Wojaczek, from Vienna, who is a native of Oslavau, in Moravia, aged about twenty-three, is the subject of a peculiar malformation of the chest, which has been examined by eminent medical men at the different universities and medical schools of Europe. This gentleman was introduced by Dr Alexander Simpson, and submitted himself for examination by the members of the Society. In front the chest presents in the middle, at its lower part, a remarkable depression or hollow, about three inches deep, and large enough to lodge the head of a child. This hollow is formed by the inflexion of the sternum downwards and backwards towards the spinal column, which it approaches so closely that, by calculation, only about an inch and a half intervenes between the lower end of the sternum and the front of the bodies of the vertebræ. There is no deficiency of the osseous or cartilaginous textures, but the cartilages of the ribs are bent backwards to join the depressed sternum and form the sides of the hollow; the skin and soft parts presented nothing unusual. In consequence of this peculiar shape of the chest, the respiration is almost exclusively carried on by the diaphragm and false ribs. This malformation appears to have been congenital, and was first discovered by Professor Skoda and Rokitansky during an illness, in which they had occasion to examine M. Wojaczek's chest. Casts of the malformation have been placed in the museums of the University and of the Royal College of Surgeons.

ON OPIUM AS A REMEDY IN POISONING BY DATURA.

Dr Thomas Anderson, of the Indian Army, read the following paper on this subject before the Edinburgh Medico-Chirurgical Society:

Benjamin Bell, Esq., in an article on 'The Therapeutic Relations of Opium and Belladonna to each other,' published in No 37 of this journal, for July, 1858, directs attention to the doctrine propounded by me some years ago, that opium and belladonna exert an opposite influence on the human system, and that thus one may be used to counteract the other, even though administered in a poisonous dose. In the summary given at the commencement of his article of the origin of this opinion, he mentions some apparently (and, to my mind, perfectly) conclusive experiments made by me in 1853 (Ranking's 'Half-Yearly Abstract,' vol. xxii., p. 303), on the action of belladonna in poisoning by opium. He further gives very interesting details of two cases of partial poisoning by atropia, which he treated successfully by the injection of morphia. While conducting my experiments in 1853, I became convinced that the converse doctrine must be true—viz., that opium would counteract the action of belladonna, and of all the solanaceæ with like properties, such as the species of datura and hyoscyamus, and perhaps tobacco. In Britain, poisoning by belladonna, or by henbane, is so exceedingly rare an accident, that it was vain for me ever to expect to meet with a case of either. However, in 1854 I proceeded to India, where poisoning by datura is of everyday occurrence; and I determined to test my theory by administering opium to the first suitable case I should have an opportunity of treating. From the unsettled state of the country during my residence in India, first from the Santhal rebellion, and lately from the annexation of Oude, followed by the mutiny of our army, my service has been entirely military; and thus I have been thrown amongst the class of natives least obnoxious to datura-poisoning. Only one favourable case has occurred to me, though I have heard of several cases that recovered, and assisted Dr Fayrer, of Lucknow, in making post-mortem examinations of three or four individuals, to whom a fatal dose had been administered. As this solitary case, however, illustrates my theory of the impossibility of these two classes of poisons exerting their action simultaneously on the brain, and is, moreover, the converse of my former experiments, and, at the same time, supplementary to Mr Bell's, I am induced to relate it in detail.

The 43rd Bengal Native Infantry, of which I was then the medical officer, while on its passage from the Punjab to Calcutta by boats, on the River Ganges, halted for four or five days at Futteyghur, in the beginning of December 1855. The sepoys were of course allowed to go on shore, and many of them visited the large bazaar in the native city of Furrackabad, two or three miles from Futteyghur, the British cantonment. Two days after our arrival, one of the sepoys, a man well known to me, was found by his comrades lying by the roadside, near Furrackabad, in a state of high delirium, and was brought to the hospital boat. On inquiry, I learned that he had been seen partaking freely of sweetmeats—(the Hindoo eats them by pounds-weight at a time)—in the Furrackabad bazaar, some hours before he was found; and the men at once ascribed his condition to poison administered in the sweetmeats. The many varieties of native sweetmeats poisoned with datura and bhang, one of the preparations of Indian hemp, are well known in all large Indian towns, and are used to cause death, or stupefaction so complete as to allow of robbery or violence being committed; and a sepoy, when in undress, usually displays valuable ornaments, sufficient to tempt a thief or thug. Even without this knowledge, the symptoms were so marked that I had no difficulty in forming my opinion of the cause of the patient's condition. I saw him immediately after he was brought to hospital, and found him in the following state: He was reclining on his back in bed, in a wakeful, muttering delirium, unbroken by an interval of even transitory consciousness. His face was much flushed; the eyes were reddened and wandering, and the pupils were brilliant, widely dilated, and quite insensible to light. The pulse was much accelerated and small. He continually twitched his extremities, but especially his hands, and every now and then pinched and tugged at the bedding. Though utterly unconscious to real external objects, the brain was evidently active, with continual visions before the eyes, as his mutterings and frequent clutchings referred to imaginary objects. He was not in the least degree violent, and required no restraint, but merely an attendant to keep him covered during his restless tossings about.

He swallowed any liquid put into his mouth, but exactly as patients in delirium tremens do, in one convulsive mouthful. In an hour after his arrival at the hospital, I began the administration of opiates, and prescribed one grain of the muriate of morphia in solution, to be given every hour, beginning the first dose at two p.m. I watched the effect most closely, taking the state of the pupil as my principal guide. Eight doses were given before I could observe any result. After the eighth dose, about eleven p.m., I noticed that his attention could be fixed for a moment, and that the muttering could be arrested by loudly talking to and shaking him; that the hands were less tremulous.

Still, no impression had been made on the widely-dilated pupils, and he was evidently as wakeful as ever. I, therefore, before retiring for the night, directed the continuance of the morphia until the morning, with orders to discontinue it so soon as sleep threatened to come on. I did not see him again until six in the morning, when I found all his delirium gone, the tremulousness much relieved, the pupils almost reduced to their natural state, and the patient surrounded by his delighted comrades, who were listening with wonder to the native doctor relating to them how "dhutona" poisoning had been cured by "apheem" (opium). Though he was able to talk, and was nearly well, I considered it advisable to persevere with the treatment until sleep had been obtained. This did not supervene until three doses more had been given.

After several hours' sleep, he awoke perfectly well; and after two days' more detention in hospital, he was dismissed "fit for duty;" and while I remained with the regiment, was never again in hospital. In all, fifteen grains of the muriate of morphia had been administered in eighteen hours; and with reference to the largeness of the amount, I took care to inquire concerning the habits of this sepoy, and found that he used opium in no form whatever.

In this case, as well as in the experiments published in my former paper on this subject, the amount of the narcotic used as the antidote, whether belladonna or opium, to restore the normal condition of the brain, would, by itself, have been a poisonous dose. This tolerance of the one poison, produced by the presence of the other poison in the system, seems to me to be a strong additional argument in favour of my theory. It also induces me to go further, and to believe that all narcotic poisons with distinctly opposite actions, and destroying life by their effects on the nervous centres, will, when present in the body together, counteract each other, until eliminated from the system by the excretions. For example, the distinct coma-producing narcotics, such as opium, will, I believe, in all cases be counteracted by the poisonous solanaceæ; and, as a remedy to the action of strychnine, I would hope for success from the use of conia, or preparations of hemlock itself; and of course in all these cases the opposite would hold true. Unfortunately, no correct conclusion can be drawn from experiments made on the lower animals, as they are variously affected by narcotics. To dogs and cats I have given morphia in enormous doses without producing almost any effect; and to them five and six grains of atropia prove quite harmless. Rabbits will feed for months on belladonna leaves, and have their pupils dilated all the time, but otherwise they are not affected. Blackbirds eat belladonna berries in large quantities and do not die.

It is, therefore, only to experiments on man that any value can be attached. In conclusion, I would request my medical brethren never to give up hope of the most desperate case of opium-poisoning; but after the failure of the usual means—such as emetics, the stomach-pump, electricity, &c.—to endeavour to produce, as rapidly as possible, the first symptoms of the action of belladonna on the system by the administration of atropia, either internally, or by injection under the skin, as indicated by Mr Bell. My firm conviction is, that in all such desperate cases (desperate as regards the old treatment), this plan, when boldly adopted, will be invariably successful.

Since writing the above, I have just heard that Dr Carnegie, medical missionary in China, in a letter lately received from him mentions a case of poisoning by opium which he had just cured by giving belladonna.—'Edinburgh Medical Journal.'

PATHOLOGY AND TREATMENT OF CHLOROANÆMIA.

Dr Eisenmann, from an extensive observation of this affection, concludes that it is especially developed under the influence of medical constitutions which predispose to nervous affections. It is especially met with at a time of life when all kinds of neuroses are very prevalent, its appearance being ushered in by nervous phenomena, at a period when as yet the blood has not undergone the slightest change. Such change may even be absent when the disease has reached its full development, nervous symptoms being observable, however, during its entire course. It is curable by agents which exert a special action on the spinal marrow; and when left to itself, it often gives rise to chronic, or even fatal, spinal affections. All these considerations lead the author to the final conclusion that chlorosis is a primary nervous affection, the change in the blood being a secondary phenomenon, due to morbid innervation. Guided by these views, he treated several cases of the complaint by means of tinc-

ture of St Ignatius' bean, with great success. Wishing, however, to effect a more prompt recovery than that which takes place when the bean alone is given, he associated it with ferruginous preparations, adding also rhubarb, on account of the constipation which is usually present. The following is the formula he employs :—Powder of St Ignatius' bean, 1 gr.; lactate of iron, or iron filings, iij. gr.; rhubarb, iii. gr. to iv.; and oleosaccharate of peppermint, iv. gr. This is repeated twice a-day. When the stomach is irritable, the iron is left out. This compound cures far more rapidly and effectually than do mere preparations of iron.—'Bull. de Thérap.'

NEUROMA OF THE OPTIC NERVE.

An extremely rare, if not unique, example of neuroma, affecting the optic nerve, was detailed at some length to the Paris Anatomical Society, by M. Duboné. It occurred in a patient upon whom M. Velpeau had operated for an orbital tumour, and who died of tetanus.—'Bull. de la Soc. Anat.,' 1859.

ARSENIC IN APOPLECTIC CONGESTION.

M. Lamare-Picquot, Physician to the Honfleur Hospital, as the result of ten years' observation and trial upon between forty and fifty cases, including his own among them, strongly recommends the prolonged use of arsenic as an effectual means of subduing congestion likely to give rise to apoplexy. In very urgent cases, in which hæmorrhage seems imminent, he precedes its employment by a moderate venesection; but this is quite exceptional. In proportion to the severity and menacing danger of the case, the dose requires to be larger; and although, even after a month, benefit may already result, to be of permanent benefit it will have to be continued for several months. The more urgent the case, the more tolerant does the system become of the arsenic. The Author, regarding apoplexy as consisting essentially in an excessive increase of globules of the blood, employs arsenic as a powerful agent for decreasing these, as well as the plasticity of the blood. It becomes, of course, necessary to assure oneself in a given case of the richness of the blood, for to employ arsenic when the blood is impoverished would be to do mischief. The Author has generally found the dose of gr. $\frac{1}{15}$ to $\frac{1}{7}$ per diem sufficient.—'Bull. de Thérap.'

M. HARDY'S PRESCRIPTION FOR ACNE.

M. Hardy, who considers acne a mere local disease, trusts in most instances to be able to effect a radical cure by external remedies. None of these preparations, however, seems to be a specific, not even the iodide of mercury and chlorine extolled by Dr Rochard. They all act by the irritation they induce in the integument previous to improvement. The agent which M. Hardy most generally prescribes in the incipient stage is the following:

R.	Aq. destill.	3¼ oz.
	Hydrarg. bi-chloridi . . .	14 gr.
	Alcohol	q. s. M.

One teaspoonful of this solution mixed with a glass of warm water is used night and morning in fomentations. Cold lotions must be carefully avoided, as they occasion injurious reaction.

Three mercurial preparations have been chiefly found beneficial in the treatment of acne: the proto-iodide, the bin-iodide, and the iodide of mercury and chlorine. M. Hardy prefers the two former, which are more easily procured and less liable to change. Every evening the patient should apply a pomade consisting of adip., 1 oz.; hydrarg. proto-iodidi, from 2 to 15 gr. The bin-iodide in doses of 1-10 grains produces the same results. Should the disease persist, M. Hardy increases the strength of the ointment, and, when practicable, he recommends the waters of Barèges, Bagnères-de-Luchon, Aix in Savoy, and more especially those of Louesche in Switzerland, springs which are found singularly beneficial in numerous diseases of the skin.—'Journal of Practical Medicine and Surgery.'

A SIMPLE METHOD OF IMPARTING AN AGREEABLE PERFUME TO COD-LIVER AND CASTOR OILS.

Therapeutics are indebted to M. Jeannel for an improvement which will facilitate the always difficult exhibition of fish oils. Like M. Sauvan of Montpellier, M. Jeannel observed that the addition of 10 gr. of essential oil of bitter almonds to 3¼ ounces of the most offensive cod-liver oil entirely dispelled its nauseous odour and fishy flavour. It was, however, not enough to disinfect the oil; it was further desirable to render it agreeable, an object which M. Jeannel has effected by very simple means: the cod-liver oil should be powerfully shaken in a phial with once or twice its volume of distilled cherry-laurel water, and the two fluids afterwards separated, after forty-eight hours' rest, with a funnel. The oil should be filtered if it has not spontaneously clarified. Brown, fetid oil acquires by this simple process an agreeable perfume and a pleasant flavour of almonds, which remains on the taste during the whole time of digestion.

With regard to castor oil, three drops of essential oil of almonds communicate to 3½ ounces of oil a pleasing perfume and taste. The 'Gazette des Hôpitaux' states that, for several months, Dr Rennes, of Bergerac, has been in the habit of successfully palliating the noxious flavour of fish and castor oils, by merely adding one drop of essence of bitter almonds to every 6 or 8 drachms of oil.—'Journal of Practical Medicine and Surgery.'

FRACTURE OF THE ODONTOID PROCESS OF THE AXIS.

Dr Watson showed a dried specimen, from his museum, of the atlas and axis articulated with each other, in which the odontoid process had been fractured close to its root. Dr Watson regretted that he had no history of this preparation. He believed, however, that it might prove interesting to the Society, as it showed several things connected with this rare and usually fatal injury. 1st. That the patient may survive for a long period after such an accident, if the fracture is not accompanied with serious displacement. That such a lengthened period must have existed, he thought, was obvious, as the fractured surfaces had become smoothly rounded off, no bony union having taken place between them. 2nd. That the absence of displacement was obviously due to the alteration of the articular facets of the atlas and axis. These surfaces were much increased in superficial extent, new osseous matter having been deposited around their margins, more particularly the anterior and external; so that their movements must have been very limited indeed, if the comparison of their irregular and corresponding outlines and certain porcellanous alterations of surface might be considered as indicating the limit of their extent of motion. 3rd. He thought it an interesting question to be solved, by the appearances present, whether the chronic rheumatic arthritis, which obviously existed in all the atlanto-axoidean articulations, preceded or followed the injury which produced the fracture? Dr Watson was inclined to believe that the chronic rheumatic arthritis was first, the injury second; and this because the ordinary alterations characteristic of this disease in the odonto-axoid joint were here present—viz., enlargement of the odontoid process, increase in the size and depth of the axoidean concavity, and porcellanous alteration of some portions of their surfaces. He could not see how any great change in size of the odontoid, or any porcellanous alteration depending upon constant friction of the opposed and altered surfaces, could take place after the fracture, for the fracture had remained ununited, implying, of course, a diminished nutrition and a want of firmness of the separated portion; while, further, he did not see, if the articular facets of the vertebræ had not already been altered in their characters, what there was to prevent the occurrence of death, either immediately upon or within a very brief period after the injury. He was, therefore, inclined to attribute the want of displacement and the long continuance of life after the injury to the fact, that chronic rheumatic arthritis had existed previously.—'Edinburgh Medical Journal.'

COBWEB PILLS.

Dr Kachul says—"I am astonished to find that the prescription of cobwebs, in cases of fever, should have been made the subject of newspaper correspondence, as if it were a *new* discovery. As Dr Colebrooke has pointed out, it is a very old prescription—and it is mentioned in Buchan's 'Domestic Medicine,' and in a foot-note at page 116 an extract is given from Dr Chapman's work, 'Elements of Therapeutics and Materia Medica.'

"'It is a very old popular belief that the spider's web cures agues; but among medical men, till within the last twenty years, little credit was given to this supposed popular superstition. In Dr Robert Jackson's late visit to Philadelphia, he mentioned the efficacy of this remedy as indisputably ascertained, and averred (what he afterwards published), that, as an anodyne to allay pain or calm irritation, it proved vastly superior even to opiates. It has for some time past been pretty liberally prescribed by Drs Physick, Chapman, and Dewers, of Philadelphia; and though they attach different degrees of value to the article, 'they are satisfied that the representation of its virtue is very little, if at all, exaggerated.' In doses of five grains, repeated every fourth or fifth hour, Dr Chapman has cured some obstinate intermittents, suspended the paroxysms of hectic, overcome morbid vigilance from excessive nervous mobility, and quieted irritation of the system from various causes.

"That used by Dr Chapman was collected in cellars, and was probably the product of the common black spider. He has also satisfied himself that the web found in light, exposed situations, the product of the grey spider, is inert; and so is the web of the other, when not recent, which may be known by its glutinous feel.

"Some twenty years ago, I and my brother, in the absence of quinine, and at a time when fever was raging, made an attempt to give cobwebs a trial, but signally failed, from a most ludicrous cause. Not being acquainted with the Telopogoo name for cobwebs, we described them to the dresser as those things that hang about dark cellars and the pagodas. The dresser, though he seemed astonished, said he knew perfectly what we meant, and would bring some the next day and give them a trial. Next day, on the dresser's coming, we asked him if he had got the thing; and on his replying in the affirmative, we told him to go and make them up into five-grain pills. 'How am I to do it?' asks the dresser. 'Why, pound them up in a mortar, to be sure; don't you know how to make a pill?' 'But they won't let me!' says the dresser. Here we twigged there was something wrong, and desired him to bring his obstreperous ingredients, which he did, in an official cover, from which he turned out some half-dozen *bats!* On our screaming with laughter, the dresser could not make it out, and said—'Why, sirs! you said, those things that hang in cellars and pagodas, and I thought you meant these!!' Since then I have never attempted to make cobweb pills."—'Indian Lancet.'

URTICARIA AS A SYMPTOM OF IRRITATION OF THE FEMALE SEXUAL ORGANS.

Professor Scanzoni observes that although it has long been known that chronic affections of the female sexual organs are not infrequently accompanied by skin diseases (as urticaria, eczema, acne, psoriasis, chloasma, &c.), the influence of a more sudden irritation of these organs upon the cutaneous surface is by no means so well established. He has been enabled to find no very definite statements upon the subject, and this leads him to communicate some cases tending to establish such a consensus.

A lady, aged 34, had been under his care for some time with slight retroflexion of the uterus, and chronic metritis, when he ordered four leeches to be applied to the vaginal portion of the cervix uteri. This little operation had been already performed once before without any ill effect; but upon the present occasion, ten minutes after the application had been made, the patient was seized with violent febrile action and slight delirium. In half-an-hour she was seen by the Author, who found her skin, and especially that of her face and upper part of her body, almost of a scarlet red. The temperature of the surface was considerably raised, and her pulse beat 136. She continued much the same during the night; and when seen next day, the face, neck, chest, arms, and thighs exhibited, together with the intense redness, innumerable urticaria elevations. In a day or two the exanthem had entirely disappeared; a distinct desquamation, however, taking place on the face and neck. As this was the first case the Author had ever seen in which these symptoms followed the application of the leeches to the cervix, he did not believe in their dependence upon this, and again ordered them to be employed. Four times this was done without any unpleasant occurrence; but on the fifth occasion the whole

series of symptoms above described were reproduced, and that so rapidly after the biting of the leeches that any doubt as to cause and effect could no longer be entertained.

In a second case, a woman, aged 28, was admitted into the Würzburg Midwifery Institution on account of chronic uterine infarctus, and five leeches were ordered to be applied to the cervix. Scarcely had they taken hold, when she complained of the most violent labour-like pains in the abdomen; and although these soon moderated in force, they were accompanied with such intense febrile action that the entire body glowed with heat, the pulse rose to 140, the carotid pulsated visibly, and the face, neck, and chest exhibited an intensely red colour, to which were added in a very short time a large eruption of urticaria elevations of a palish colour. The eruption was accompanied by great headache, inclination to vomit, and excessive lassitude; symptoms which continued to the following day, although the exanthem with the accompanying fever disappeared entirely after three hours' continuance. This patient had often suffered from urticaria at the menstrual periods, without, however, its being accompanied by such violent symptoms.

The third case occurred in the person of a young lady, aged 26, who, on account of long-continued chronic oöphoritis and metritis, required local blood-letting. In the course of sixteen months four or five leeches had been applied eight times. On the ninth occasion, an intense redness covered the skin, and the patient complained of the most violent pain in the head. The temperature of the surface was much raised, and it was almost entirely covered with innumerable minute, prominent, white elevations. In the course of an hour these appearances gradually subsided, the headache continuing for twenty-four hours longer. The Author is aware of a fourth case of the same kind, but is unable to furnish the particulars.

Professor Scanzoni believes that these cases deserve the attention of those occupied with the diseases of women, as well as of dermatologists. They admit of no other explanation than that the irritation of the uterine nerves, caused by the bite of the leeches, induced an entirely unusual, and in its mode of origin inexplicable, disturbance of the vascular system, which again, in a mode which is to us equally unintelligible, gave rise to the production of the eruption of urticaria. In proof that these appearances were not produced as a consequence of any poison being conveyed through the medium of the bite of the leech, it is to be observed that similar symptoms never result from the application of leeches to other portions of the body, while it is to be observed that even very slight irritation of the sexual organs, as that produced by examination with the finger or speculum, or by the application of caustic, will in many very sensitive women give rise to erythema of the face, neck, breast, &c., which disappears as rapidly as it comes on.—'Würzburger Medicin. Zeitschrift,' band i., pp. 90—95, and 'Medical Times and Gazette.'

LEGAL INTELLIGENCE.

CENTRAL CRIMINAL COURT.—Sept. 19.
(Before Mr Justice Byles.)

THE COLNEY HATCH LUNATIC ASYLUM INQUIRY.

William Slater and William Vivian were charged with the manslaughter of William Swift. Both the prisoners were stout, powerful men. They had been admitted to bail, and surrendered to take their trial.

Serjeant Ballantine was specially retained, with Mr Sleigh, to conduct the prosecution, which was instituted by the direction of the Lunacy Commissioners. Mr Metcalfe appeared for Slater; and Mr Robinson and Mr F. H. Lewis were counsel for the other prisoner.

Serjeant Ballantine, in opening the case, said he had the honour to appear on behalf of the Commissioners of Lunacy, who had felt it their duty to institute the present prosecution; and the inquiry was certainly one of a most important kind, and which would require their most serious consideration. The learned counsel then proceeded to give a brief narrative of the facts of the case, and said that the prisoners were keepers employed at the Colney Hatch Lunatic Asylum, and the offence imputed to them was causing the death of one of the unfortunate inmates by brutal violence. He was bound to admit that the charge merely rested upon the evidence of two witnesses who were undoubtedly lunatics, and it would be for them to consider what value ought to be attached to their testimony; but, whatever might be the result, he was sure they would agree with him that the inquiry was a most important one, not only to the unhappy inmates of those asylums, but also to the public.

The following evidence was then adduced:—

William Gann deposed that he was one of the keepers of the Colney Hatch Lunatic Asylum, and generally was employed in the C ward. In March last the deceased was placed under his charge. He was fifty years old, and a strong, powerful man. On the evening of Wednesday, the 9th of May, in consequence of hearing the deceased make a noise, witness went to him, and he struck him immediately in the eye, and at the same time seized him by the throat, and said, "I've got you now, you ——." He seized hold of him, and they both fell, and he did know anything more that happened till he was released by another keeper. Witness struck the deceased during the struggle in the stomach. (The witness pointed out the spot where he struck the deceased.) He saw deceased again the same evening about eight o'clock, and he made no complaint of injury. He saw him again the next morning, and the deceased showed him a bruise in the stomach, at the place where he had struck him. He did not appear to be suffering in any manner, and he did not exhibit any symptom of difficulty of breathing. He wished to sweep the ward as usual, but witness would not allow him to have a broom. He ate all his meals as usual, and after he had had his dinner he removed him to No. 11 ward, by direction of Dr Tyerman, one of the medical officers. This was done in consequence of his violence on the previous day.

Cross-examined: He struck the prisoner as hard as he could. It was a life and death struggle between him and the prisoner, and he was nearly strangled when assistance arrived. They both fell with considerable violence upon the boarded floor. The deceased seized hold of him the instant he opened the door of his room. He had been knocking at the door and shouting and making a great noise before witness went to him. No. 11 ward was a place appropriated for violent patients, and it was called the 'refractory ward.' The deceased was frequently violent, and often sparred at the other patients and wanted to fight. There were marks on both wrists where he had been chained down at some former time.

Charles Reed, an attendant in the asylum, proved that on the 9th of May he was called by one of the patients to the assistance of the last witness. He found him lying on the floor, and the deceased had him fast by the neck-tie. Witness laid hold of him and told him to leave go, and he did so immediately, and Gann then got up. He then told the deceased to go to bed, and he did so directly. He made no complaint at this time, and did not appear to have received any serious injury. On the following morning the deceased told him it was a lucky job for Gann that he came up the evening before to his assistance, or else he should have killed him.

Cross-examined: The deceased's principal delusions were that he was possessed of large property, and that he was the strongest man in the world. He also used to say that he had killed three or four hundred Catholics.

Mr John Berry, the head attendant at the asylum, deposed that he saw the deceased on the day he died (Saturday, the 12th of May), in the airing court, at four o'clock in the afternoon. At this time he appeared in his usual health and strength. The deceased was partial to him and followed him about, and told him he thought he could infuse strength into any one by breathing into his mouth.

Cross-examined: The deceased complained of having received a blow from Gann, and pointed to the part of the abdomen where he had struck him. He made no complaint of having been ill-used by any one on the Friday, and he never made any complaint of having been ill-used by the prisoners. Witness knew the patients Clark and Varney. The latter had almost always been in the refractory ward. Clark was also a very violent man, and frequently struck the other patients, and he considered him a spiteful man.

Re-examined: When he saw the deceased on the Friday, he did not appear to be suffering in any manner, and he did not observe any difficulty of breathing.

Thomas John Lord, another attendant, deposed that he saw the deceased between four and five in the afternoon of the day of his death, and he did not observe that there was anything the matter with him; and he did not appear to be in any pain, and made no complaint.

Cross-examined: The patient Clark was a fretful man, and prone to fight. His insanity showed itself by excitement and violence; and he laboured under many delusions of different kinds, and frequently assaulted the other patients.

Re-examined: Witness would not rely implicitly upon anything Clark represented to have occurred in the ward.

Dr Stocker deposed that he was a physician and medical superintendent of the Grove Hall Lunatic Asylum, Bow. The two men, Clark and Varney, whose names had been mentioned, had been under his charge for a month, and he believed that they were both competent to give a correct account of matters that came under their personal observation.

Cross-examined: Witness was not aware that these men were placed under his charge for the express purpose of ascertaining whether they were competent to give evidence or not. They were placed under his care by the authority of the magistrates for the county of Middlesex, and he had instructions to pay attention to their mental condition. The man Clark was undoubtedly subject to delusions, and he judged of the truth or falsehood of any statement made by him by its probability or improbability.

By Mr Robinson: Clark was under the delusion that poison had been administered to him, and that his system was very much injured by it, and he seemed really to believe that this was the case. The other man, Varney, was under the delusion that he had been the victim of persecution by a variety of parties. He could not discover that he laboured under any other delusion.

Re-examined: A lunatic might have a delusion upon one subject, and yet be quite reasonable upon others, and quite competent to state facts correctly with regard to any occurrence that took place in his presence.

Sergeant Ballantine then proposed to call the two lunatic patients as witnesses.

Mr Robinson said that before these witnesses were examined, he should like to take the opinion of the learned judge whether his learned friend had a right to call them without giving some further evidence that they had sufficient lucid intervals to render them competent to give their testimony, and that the jury would be justified in relying upon it.

Mr Justice Byles said it had been distinctly laid down that a lunatic was not disqualified from giving evidence, and he could not stop the examination of these witnesses unless the learned counsel was in a position to produce evidence to show that they were in such a state of mind that their evidence could not be relied upon.

Mr Robinson said he was not prepared to produce evidence upon this point, and he therefore withdrew his objection.

Samuel Clark, the lunatic witness, was then called in and examined. The witness, who is a tall, powerful man, was, at the suggestion of the learned judge, not examined from the witness-box, which is quite close to the jury, but in the body of the court. He said: I used to live at Colney Hatch. I know the two men at the bar. They were attendants at the asylum. I knew the deceased man Swift, but did not hear of his death until the Tuesday, after it happened. On the Saturday afternoon before, Mr Vivian came into the ward about four o'clock, and caught him by the hand and the collar to drag him out, and Swift said he would go with him quietly. Mr Slater was present, and Vivian said he had been waiting for him, as he could not get Swift out of the ward. Slater then said that they had better get him out at once, and Vivian tripped his legs from under him and he fell to the ground on his back, and they then both kicked him, and punched him, and stamped on him with their feet. After this they took him into the padded room, and he could not see what occurred, but he heard them ill-treat him, and heard him cry out "murder" once, and he also called out to them not to kick

him and ill-use him. I afterwards went out to the airing court, from whence I could look into the padded room, and I saw the deceased lying on his back and drawing his legs up, and Slater had his hands on the deceased's head.

Cross-examined: The noise could be heard all over the building by the patients, and also by the attendants. I saw three or four, or half-a-dozen kicks given to the deceased by both prisoners. They kicked him principally in the sides and ribs, and Slater also stamped upon his chest. He did this with his feet, and also with his knees. Both prisoners also "punched" the deceased with their fists, but Slater was the most violent of the two. I saw them do this in the airing court, and I saw the same thing in the padded room. I have had something given me that has done me great injury. I have not been out of the doctor's hands since. I was poisoned when I was in Sydney, and I was poisoned again shortly before I went to Colney Hatch. I have been poisoned a good many times. I am very nervous, and it does not take much to make me so. Swift complained the same day of the injuries he had received, and said that his ribs were nearly broken. He said that those two brutes—meaning the prisoners—had nearly broken his ribs. I did not say anything about this until the 2nd of August, when I was examined by the commissioner. I did not tell the other patient, Varney, anything of what I had seen, and I did not talk about it to any of the other patients. Varney said to me once that it was pretty work that was going on, but it would not last always. I never told any of the attendants in the asylum that I had been poisoned. I was afraid to talk about what I had seen in the asylum, in case I should be ill-used myself.

By Mr Robinson: Another patient named Overhall was near the padded room when the occurrence took place, but he did not look into the room. He could have heard all the noise and cries of the deceased. The kicking and the stamping lasted nearly an hour, and the deceased was screaming the whole of the time. He called out to them once to kill him, and not to keep kicking him. It seemed to have an effect upon me, and after it was over I went to sleep.

William Varney, the other lunatic witness, a respectable-looking man wearing a large beard, was then examined. His statement was similar to that made by Clark, but referred to other acts of violence alleged to have been committed by the prisoners. He said that, after dinner on Friday, the 11th of May, the deceased was making a noise and "talking nonsense," when the prisoner Slater very roughly told him to be quiet, and then seized hold of him to drag him to the padded room. The other prisoner assisted him, and they both got him into the padded room, and when he was there he heard him say "Oh!" and "Oh Lord!" several times, and there was a noise as though persons were scuffling. He did not see the deceased again until the next morning, when he said to Slater it was too bad to kick him so, and put his hand to his breast. The prisoner took no notice of what he said. Swift appeared to be in a great deal of pain at this time, but he ate his dinner as usual.

Cross-examined: He did not notice whether Clark was near enough to hear the cries of the deceased. Several of the other patients were quite close to him. Witness had been two years in the asylum. He was removed from Hanwell to Colney Hatch. He was at the former asylum for ten years. He had made complaints before to the commissioners of having been ill-used several times by the attendants at Hanwell. His beard was cut off by violence, and six or seven strong men held him down while his face was being rubbed with pumice-stone. His face was cut by the pumice-stone. All this was done by the orders of the authorities. He complained to the doctor of the manner he was treated, and he only laughed at him. He did not recollect having talked to Clark about what occurred on the Saturday, and how Swift had come by his death; but he knew that he was somewhere in the ward at the time it happened. Eight or nine other patients might also have seen it, and there were about forty patients altogether in the ward. The violence in the padded room lasted about ten minutes or so. The patients were very different in their ways.

Mr Robinson: Some of them are a great deal more mad than others, I suppose!—Witness, yes, sir; some of them would not take that notice of the cries and disturbance that others would.

By the Court: Swift was not a violent man. I never saw him offer to strike any one.

Dr Tyerman, medical superintendent of the Colney Hatch Lunatic Asylum, deposed that the deceased was one of those patients considered to be a dangerous lunatic, and on the 10th of May, in consequence of his attack upon Gann, he was removed to the ward appropriated for refractory patients. There were about forty other patients in the same ward, and they had three attendants. He saw the deceased two or three times between the 10th and the day of his death, the 12th, and felt his pulse. On the evening of the 12th, Slater came to him and told him that Swift was very ill, and either dying or dead, and that he had a fit. When witness got to the asylum the deceased was dead, and he observed a large bruise upon his stomach and right side. Witness made some inquiries of the prisoners, and they both said that he had had a fit, or two fits. They also said that he had partly recovered from the first fit, and that he then got worse and they put him to bed, and both prisoners said they deemed it to be an epileptic fit. There was a post-mortem examination on the following Monday morning, and it turned out that the arch of the entire chest was fractured, and several ribs on each side were also fractured. There were also two slight ruptures of the liver, and there were two or three pints of extravasated blood in the stomach. (The witness then read the notes made by him upon the post-mortem examination, describing the appearances presented by the deceased.) At this time there was no suspicion that the prisoner had used any violence towards him. The deceased had once before attempted to strangle the master of a workhouse.

Cross-examined: The deceased was paralysed when he was admitted to the asylum, and his condition in this respect would render him less sensible to pain, and in some cases, he believed, it would occasion complete insensibility to pain. Patients afflicted with this form of insanity would sometimes attempt to walk about with broken limbs. He had seen several instances of this kind during his experience at Colney Hatch. In one case a patient who had fractured his knee-cap walked about, without any apparent pain, very shortly afterwards. In another instance, after a patient died, it was found that several of his ribs were fractured, and on the morning of the day of his death he said that he was quite well. He heard that this patient had sustained the injury in question by falling over his bed or over a chair. Cases of this sort were constantly occurring in lunatic asylums and other places. If there had been such a kicking and stamping upon the deceased as had been spoken of by the witnesses Clark and Varney, he was of opinion there must have been some external marks; but none such were visible upon the body of the deceased. It was his opinion that many of the injuries sustained by the deceased might have been caused by the struggle with Gann, and the blow he received from him on the Wednesday before his death. He had known Clark and Varney for some time, and they had been under his care, and he was of opinion that no reliance could be placed upon any statement made by them, and if he were upon a jury he certainly should not give any credit to them. They were both subject to various delusions, and Varney had decidedly a homicidal tendency, and a desire to conspire to destroy the lives of others.

Re-examined: There were no external marks to indicate by what means the ribs and sternum became fractured.

At this stage of the case the Court adjourned, in order that the jury might take some refreshment, and the trial was then proceeded with.

Dr Tucker, the assistant medical officer of Colney Hatch Asylum, deposed that he saw the deceased between twelve and one o'clock in the morning of the day in which he died, and felt his pulse, which was moderately good. He made no complaint, and there was nothing to indicate that he had anything the matter with him.

Cross-examined: The deceased made no complaint of violence being used to him on Friday evening. He had heard the description given by the witnesses Clark and Varney, and he was of opinion that if the deceased had been kicked and stamped upon in the way they represented, for nearly an hour, there must have been some external marks of violence. Witness had had a good deal of experience with insane patients who were at the same time paralytic, and he was aware of several remarkable instances of their apparent insensibility to pain. In one case, where a patient had broken both the bones of his right leg, he pulled off the splints and tried to walk about on the stump without exhibiting any appearance of pain. He considered it quite possible that all the injuries might have been caused on the Wednesday, and the deceased might not have exhibited any indication of the injury during the interval between that day and his death.

Mr Partridge, one of the senior surgeons of King's College Hospital, and professor of anatomy for twenty years, deposed that he had been in court and had heard all the evidence that had been adduced, and particularly that portion of it relating to the injuries the deceased was alleged to have received. His opinion was, that it was impossible for such injuries to have been inflicted on the Wednesday without the deceased exhibiting marked symptoms of having received them during the interval between that time and death. The consequence of so many ribs being broken would be to most materially affect the respiration, and the patient could not breathe regularly, but would do so with great difficulty, and in such a manner as must immediately attract attention. According to his judgment, the injuries that were the cause of death had been inflicted not more than two hours before. He did not think that the fact of the deceased being a lunatic would have made any difference in this case, as to the consequences of the injuries that had been received. Lunatics who had met with an accident, or who had received injury from any cause whatever, would no doubt act very differently to sane persons, and they might under some circumstances exhibit an indifference to pain; but in this case the chest would have entirely lost the support of the ribs, and the effect upon the respiration, in his opinion, must have taken place, and the patient could not have control over it.

In cross-examination, Mr Partridge said that if so much violence had been used towards the deceased as had been deposed to by the two witnesses Clark and Varney, he should certainly expect there would be some external marks upon the body of the deceased.

Mr Luke, vice-president of the Royal College of Surgeons, surgeon to the London Hospital, and to St Luke's Hospital for Lunatics, gave evidence similar to that given by Mr Partridge. He also said that he agreed with that gentleman as to the possibility of a lunatic evincing an indifference to or concealment of pain in some cases, but that this could not be done when a patient had received such injuries as were exhibited in this case, and that the difficulty of breathing must have been apparent.

Mr Barnard Holt, one of the surgeons of Westminster Hospital, gave similar evidence, and this closed the case for the prosecution.

Mr Metcalfe then proceeded to address the jury for the prisoner Slater, and in the course of a very able speech he said that the charge against him was one in itself of a very extraordinary character, and it was sought to be supported by evidence equally extraordinary, namely, that of two lunatics; and he expressed his confidence that no jury would feel themselves justified in convicting two respectable men of felony and ruining their prospects for life upon evidence of such a character. He called their attention to the facts, and remarked upon the violent character of the deceased, and the probability that he had received the fatal injuries during the struggle with the warder Gann, upon the occasion when he made the desperate attack upon him. He observed that the occurrence was proved to have taken place in what was called the refractory ward, which was inhabited solely by violent lunatics, and he asked the jury whether anything could be more likely—supposing they should not believe that the fatal injuries were received on the Wednesday—than that some act of violence might have taken place among the lunatics themselves, during which the deceased, who was proved to have been a quarrelsome, violent man, might have received them. It was, he said, admitted that the witnesses were liable to delusions, and he urged that, for anything that appeared to the contrary, the tale they had told about the violence used by the prisoners to the deceased might be an entire delusion.

Mr Robinson also made an eloquent speech to the jury on behalf of his client. He went over a good many of the topics that had been urged by the other learned counsel, and particularly called the attention of the jury to the fact that they were asked by the prosecution to convict the prisoners of this serious offence upon the evidence of witnesses who were under no moral or legal responsibility, acknowledged lunatics, who could not be indicted for perjury even if it was proved that they swore ever so falsely, and who were, in fact, utterly irresponsible for the consequences of the evidence they had given.

Mr Justice Byles, in summing up, said the case was undoubtedly one of very great importance to the public generally, to the unhappy persons confined in these asylums, and also to those who had the charge of them; and he then called the attention of the jury to all the important facts bearing on the inquiry, commenting upon them with the greatest impartiality as he proceeded.

The jury, after deliberating a short time in the box, retired. They were not absent more than a quarter of an hour, when they returned into court, and found both prisoners Not Guilty.

There was a slight attempt at applause when the verdict was pronounced, but it was speedily repressed by the officers of the court.

MEDICAL NEWS.

Royal College of Surgeons.—The next anatomical examination for the membership of the College has been fixed for Monday, the 5th November, and following days; and the next surgical or pass examination for Thursday, the 1st November, and following days.

Apothecaries' Hall.—At Courts of Examiners held on Thursday, the 13th, and Thursday, the 20th instant, the gentlemen whose names are immediately subjoined, having passed the necessary examinations in the science and practice of Medicine, were admitted Licentiates of the body, viz.: Messrs Charles Henry Bennett, of College House, Hammersmith; George John Bennett, of Gateshead, Durham (M.R.C.S. 1859); and Daniel Taylor, of Bury, Lancashire. And at the same courts the following passed the first examination, viz.: Messrs William Reginald Beck, of Great Russell street, Bloomsbury; Elijah Barker, of Sheffield; Herbert Frederic Henry Barham, of Maidstone; Henry Stanley Gale, of High Holborn; Henry Holman, of Crediton, Devonshire; William Hugh Hughes, of Warrington, Lancashire; Robert Iliffe, of Coventry (M.R.C.S. 1860); and William Pitt, of Willenhall, Staffordshire.

Royal Orthopædic Hospital.—The half-yearly court of the governors of this hospital was held on the 20th inst., at the offices, 315 Oxford street. Mr Quarles Harris occupied the chair, and stated that a number of applications for the benefits of the hospital had been received from persons who, it was imagined, moved in a higher sphere than those for whom it was designed. The decisions concerning such applications were always postponed, in order that inquiries concerning the position of the applicants might be made; for although the governors always wished to deal mercifully, yet they were bound faithfully to administer the funds of the hospital. The secretary stated that 778 patients had been admitted during the half-year, and that the total number admitted since the opening of the institution had been 26,048. The Marquis of Westminster had just sent another donation of 25*l.*, and it was stated that Miss Burdett Coutts was a yearly contributor to the amount of 20 guineas. Attention was drawn to the fact that the mortgage debt on the institution is 6,000*l.*, and entails an annual charge of 300*l.* Additional subscriptions are urgently needed to meet more than 200 cases which are in waiting, and cannot be taken in owing to the want of funds. After the routine business of the court had been transacted, it was closed by a vote of thanks to the chairman.

Metropolitan School of Dental Science.—The second session of this school will commence on Wednesday, the 10th of October, when the Introductory Lecture will be delivered by Mr Hulme, at 8 p.m. Lectures will be delivered on Dental Surgery, by Mr Hulme, on Thursdays at 7; Anatomy and Physiology, with Demonstrations from the subject, by Dr Richardson, on Wednesdays at 7; Dental Mechanics, by Mr Perkins, on Thursdays at 8; Comparative Anatomy, by Dr Cobbold, on Wednesdays at 7; Principles of Surgery, by Mr T. Spencer Wells, on Fridays at 7; Chemistry and Metallurgy, by Dr Bernays, on Wednesdays at 8.

A Learned Charlatan.—Thomas Woolhouse is the first modern author who has called the attention of the Profession to the passage of Hippocrates which refers to scarification of the eyelids. He was oculist of James II., and settled in Paris about the beginning of the 18th century. He was a Graduate and Fellow of Magdalen College, Oxford, skilful and very learned; but his place in history is in the rank of those for whom science is merely a means of arriving quickly at fortune. He made use of this very passage of Hippocrates to carry on his charlatanism. In this passage, he said, which no one before him had understood, scarification of the eyelids was indicated,—a sovereign remedy for a great number of ophthalmic diseases. He only knew the mode of performing it, and this he kept a secret. In his works he speaks only of the operation and the instrument with which he operated, but gave no description of it. He, in fact, kept it a complete mystery, and only permitted his pupils and intimate friends to be present when he practised it; and when he initiated them into the secret, he made them pay a good round sum for it, and also swear to keep it secret.—'Med. Times.'

Air-purifying Ventilators and Refrigerators.—The news of the deaths of Sir H. Ward and Mr Wilson, from the effects of the climate of India, suggests the consideration that less progress has been made in the means of preserving the health of Europeans in India than might have been expected in an age when the powers of steam and electricity render such signal service to man. These deaths forcibly remind us of the extreme importance of the plan suggested and recently patented by a Medical man, and described in a recent number of our journal. We allude to Mr White's air-purifying ventilators and refrigerators. The process is effected by forcing a current of air through plates of metal filled with small perforations, down which water is falling. The motion of the air is produced by a fan which is moved by hand, or by water issuing from a "Barker's Mill," or by any other motive power; and the motion of the water on the perforated metal is produced either by causing circular metal plates to revolve with half their substance immersed in water, or by causing the water issuing from the Barker's Mill to fall on perforated metal. The air on contact with water colder than itself is cooled by evaporation and conduction. With water artificially cooled with ice (which is plentiful in the chief cities of India), and the use of this simple and inexpensive machine, the temperature and purity of the air in an apartment in the hottest and most unhealthy parts of India will be like that of England. It is not as an article of luxury, but as a means of preserving the health and lives of our countrymen in India, that we recommend this refrigerator. The machines may be seen at Mr Harris's, 21 King William street, Charing cross, from two till five p.m.

APPOINTMENTS FOR THE WEEK.

Wednesday, September 26.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, September 27.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.

London Home.—2 p.m.

Friday, September 28.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, September 29.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, October 1.

Operations at the Royal Free Hospital, 2 p.m. Metropolitan Free Hospital, 2 p.m.

Tuesday, October 2.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

A Subscriber.—1st. St Bartholomew's or the London Hospital for general surgery; for operations, King's College is famous.

Anodyne.—The composition of chlorodyne, as given in our Journal, we are informed is, if not quite, at least approximatively correct. Mr Davenport is, of course, justified in denying its correctness if it vary ever so slightly from the authentic one.

Dr B. H.—A good and cheap microscope can be had at Baker's, in Holborn.

Palmam qui Meruit, Ferat.—It is unnecessary to open a controversy upon the point. We do not consider it in question.

L.S.A.—The regulations as regards preliminary education are only the recommendations of a Committee, and are, of course, not yet in force.

Beta.—You are still within the period.

Senex, on the Degree of M.D., received.

Chirurgus Alter.—Enclosures received. Our correspondent is thanked.

A Student.—We cannot inform you.

Tyro.—Such an arrangement can be made in several schools.

Deodorization in Obstetric Medicine.

To the Editor of the Medical Circular.

Sir,—Dr Skinner's paper on the above subject is of great value. But as with the poor especially the general use of a deodorizer in the lying-in chamber will depend much on the price and facility of obtaining the deodorizing powder, I suggest that "Condy's Health Powder" should be used in the manner advised by Dr Skinner. It will also probably be found equally, if not more useful than the applications recommended by Dr Skinner in the other cases of disease named by him.

I am, &c., John White, M.R.C.S.

Hospital for Diseases of THE SKIN, New Bridge street, Blackfriars. Between 700 and 800 cases attend weekly. The Out-Patients are seen on Mondays, Wednesdays, and Thursdays, at Four o'clock p.m. Particulars can be obtained by application to the Secretary and Dispenser, at the Hospital.

Kent's Pharmaceutical PREPARATIONS OF BRITISH MEDICINAL HERBS.—These Preparations have received universal approbation, and gained first Prizes at the London Great Exhibition in 1851, the Paris Exhibition of 1855, and also the New York Exhibition. They may be obtained of Mr W. Kent, Walsham-le-Willows, Suffolk; or of his Wholesale Agents, Mr W. H. Bucklee, Chemist, 86 New Bond street; or Mr C. F. Buckle, 3 North place, Gray's-inn lane, London.

Human Osteology from France.—RAGINEL, 38 Ludgate hill, City, E.C., London. Patronised by the Royal College of Surgeons of England. Illustrated Osteology on the bones themselves. Very large stock on the lowest possible terms. Disarticulated Skulls, in twenty-two pieces, in box. All the bones of the disarticulated skulls will be fitted in right order in the presence of the purchaser, so as to show that every bone of each set belongs to the same skull; it will be the same for all other disarticulated pieces. Skulls with Sections. Hands and Feet on cat-gut. Disarticulated Skeletons, quite complete, with the Skull same body. Articulated Male Skeletons, the bones very well marked.

STUDENT'S CASE OF OSTEOLOGY, COMPLETE.
Splendid Pieces for Lecturers and Museums.

Save Half your Coals, Cure your Smoky Chimneys, have a plentiful supply of Hot Water in the Kitchen, and a warm Bath always ready, night and day, by using the PATENT AMERICAN KITCHENER: A cheap and perfect Cooking Range, which will cook for a large family at a cost for fuel of one shilling per week, and may be seen in operation daily at the American Stove Warehouse, 155 Cheapside, E.C.—Illustrated Prospectus free.

Microscopes.—J. Amadio's BOTANICAL MICROSCOPES, packed in mahogany case, with three powers, condenser, mincers, and two slides, will show the animalcula in water, price 18s. 6d. The 'Field' newspaper, under the gardening department, gives the following valuable testimony:—"It is marvellously cheap, and will do everything which the lover of nature can wish it to accomplish, either at home or in the open air."—June 6th, 1857.—Address, 7 Throgmorton street.—Just published, Second Edition, an Illustrated and Descriptive Catalogue, containing the names of 1,500 Microscopic Objects. Post free for six stamps.

Monuments, Tombs, Head STONES, &c., ERECTED in town or country, and at any of the Cemeteries, at moderate charges, by S. H. GARDINER, Monumental Mason, New Kent road, S.E.—A Sheet of Designs, with Price List, forwarded on application.

Established 25 years.

INTRODUCTORY LECTURES
DELIVERED AT THE
OPENING OF THE SESSION
1860-61.

The usual Introductory Addresses were delivered on Monday, and, as is our custom, we append abstracts of the greater number. There was a large attendance at most of the Schools.

ST BARTHOLOMEW'S.

Mr SAVORY commenced his lecture with an earnest congratulation to those who were entering for the first time the profession of Medicine, inasmuch as henceforth they might become possessed of illimitable means of doing good, and find unbounded scope for the exercise of the noblest faculties of their nature; pointing out, that although by no means the direct route to wealth and titles, they might fairly weigh in the balance of their esteem the advantages it had to offer.

To begin with the lowest wealth, if vast incomes are not common, sudden failures are very rare. If scientific labours are not rewarded with State honours and pensions, it is a tribute to the labourer and the work; it is because the result is not limited to the aggrandisement of any sect or party, but its value is universal. No man or party rewards, because all men, all parties, are benefited and advanced. But are not such labours in themselves ennobling? Is there no heraldry in science? Would titles have added a single ray to the lustre of such names as Harvey or Hunter? The superior claims of scientific labours are almost universally acknowledged: what studies can rival these in their influence upon the mind—what others so well engage and exercise all our faculties, and enlarge them? No class enlists so many volunteers as the natural sciences; we see men stepping out from all professions, as it were instinctively, into our domain. What a popular instrument the microscope! How attractive to many the laboratory of the Chemist! No subject can be broached so sure of entirely absorbing the attention as that of our structure and functions. So, then, what others turn aside to seek, lies directly in our path of duty. It is a happy lot for us that we can earn our bread in the midst of the most ennobling and exalting inquiries. It is to us not only beneficial, but absolutely necessary. He alone can become a sound and successful practitioner who has been a diligent student of those sciences which investigate our structure and functions in their healthy and natural state. I allude to anatomy, chemistry, and physiology. Let each one learn as much of these as he can, bearing always in mind the great object for which they are studied here, never neglecting the purpose to which they are to be applied. But remember, too, that Medicine and Surgery are founded and raised upon the natural sciences; all that they are beyond mere empirical arts, they owe to their dependence upon and their association with these. It would be difficult to find a man in our profession who has attained to any great eminence in the practice of his profession, or who by his writings and precepts has advanced our knowledge of disease, or our power over it, who did not lay the foundation of his success in the distinction which he earned by his labours in the natural sciences. They found time for all this work; nay, it was well invested—for by it they were enabled to do so much and to such good purpose ultimately. Your object must be to study anatomy, chemistry, and physiology, with a view to becoming sound and scientific physicians and surgeons.

If the practice of our profession does not lead to popularity and public applause, think, if you do not win the many, in what an enviable relation you may stand to the few. How much good is done without remuneration, commonly so called! Where is the consulting-room that refuses to acknowledge the passport of pain and poverty. Moreover, our science and art are of almost universal application. Wherever man exists, there is he the subject of disease and injury, and is therefore in need of the resources of Medicine and Surgery. But if to us so much is given, from us how much is required! With more than ample scope for the exercise of the highest faculties with which we are endowed, how powerfully are we appealed to, to cultivate every faculty that we possess! With this investment for our talents, shall we, on the plea that they are small, bury them? That which the profession of Medicine has to offer is open to all—are you excluded! Why? On what does success in life depend? The most "gifted" men often fail in life. The most successful men are by no means always the most "gifted." But mark this. Success is constantly associated with work. It is never really seen apart from work. Look into the history of men who have made themselves known, and you will find one great rule in common: Industry—earnest, persevering industry. Through what grand struggles have they passed! noble illustrations that difficulties form the cradle of excellence. What is success? The attainment of the end we have in view, the accomplishment of that for which we strive. Whatever the object may be in view, it can be accomplished only by labour, labour proportionate to the result. How important that the object chosen be a worthy one! Do not let us cast our offering before an ignoble shrine.

Genuine work is no trifling matter—no less than the entire devotion of all our faculties to the difficulty to be overcome. The earlier the effort is made, the more readily is the power of application attained. If a sure foundation of elementary knowledge be not laid—lacking this firm support, the future work can never be relied on. To lay this first great stone, Gentlemen, is our business here to-night; and then we can build around it and upon it—not hastily, but securely—not for display, but for endurance. Test, and examine, and scrutinise each portion before you leave it, and ascertain that it will bear whatever weight you lay upon it in the future; and then, when the structure becomes conspicuously high, no one shall detect a disastrous flaw in the corner-stone.

Perhaps there is no subject in which erroneous opinions are so commonly entertained as the means whereby distinction has been won. There are so many fables to be told of sudden achievements in inspired moments, and of wonderful discoveries through accidental circumstances;—such for, example, as the pretty fictions of Newton and the apple—Galileo and the lamp—Young and the soap-bubble;—that it is made to appear as if chance and genius were the sole conditions of eminence. These fictions have no place in the pages of genuine history. Wherever you read the full and faithful record of the life of a great man, there you read the tale of a life of earnest, persevering labour. I am not attempting to deny there is more than this—that so much could have been done without more than ordinary intellectual powers; but with these there is always combined, as the inevitable condition of success, extraordinary work—nay, more, in many cases extreme difficulties at the commencement. The biographies of orators, poets, philosophers, historians, statesmen, soldiers, are all alike records of the fact. There is the best evidence of the extreme labour which Cicero and Demosthenes bestowed upon their orations. They were not in the habit of trusting to their genius—they made it by their industry. If there is one branch of excellence which more than another is supposed to be the gift of untutored nature, it is the faculty of verse; yet Lord Byron said he had revolved some of his compositions for whole years in his mind before he had attempted to write them down. Wordsworth spoke of the immense time he required to write even the shortest copy of verses before he could satisfy himself. What an admirable history of resolute labour is the life of Southey!

Of Newton it has been said, "Even his recreation consisted only in a variety in his industry; it is told he wrote his Chronology fifteen times before he was satisfied with it." There are similar records of the labours of Burke, Hume, and Gibbon, and many others. Frederick the Great and Napoleon, like Cæsar, worked prodigiously. Still more interesting to us the labours of the great men of our own Profession—of Harvey, Jenner, and Sir Charles Bell. Great was the genius of Hunter, and how great his labours! Johnson has defined genius to be "a mind of large general powers accidentally determined in some particular direction."

Buffon says of genius, "It is patience." John Foster held it to be the power of lighting one's own fire. "Genius," says Carlyle, "means transcendental capacity for taking trouble first of all." Although these and similar sentiments, which have been expressed by Newton, Locke, Helvetius, Diderot, Michael Angelo, and Reynolds—who held that excellence in art, however expressed by genius, taste, or the gift of Heaven, may be acquired—may, in some sense, be exaggerations; for it must be admitted that no amount of industry alone could have made men like some of these; yet it shows the estimation in which these men held work, and the confidence they had "in the omnipotence of human labour."

The most distinguished men have been invariably the most indefatigable labourers. The power of labour in subduing difficulties, and the absolute necessity of study as the inevitable condition of success, even in those whom Nature has most liberally endowed, is still more strikingly shown in the recorded examples of early failures and subsequent success. Examples — the perseverance of Demosthenes and Curran—Lord Byron's and others' first attempts—the behaviour of Frederick the Great, and Wellington's first campaign. "Depend upon it, Gentlemen, genius commonly means labour, and inspiration is only another term for industry."

There is no waste of time or stagnation in Nature, but work everywhere; for even in her most perfect production we are permitted to recognise the consummation of work. Moreover, we see everywhere by what humble and apparently insignificant agents the grandest results are attained. Witness, for example, coral reefs, and the chalk and other formations. Also observe the all-important agency of time as an element in the production of the grandest results. So it is our duty to work—a duty we owe to ourselves, to our friends, to those around us, to our hospital, to our profession, to our patients. In no quality of the mind do men differ from each other so remarkably as in what is called the power of the will, and in the relation which it bears to the passions and emotions. As by the presidence of the will man is especially distinguished from the animals below him, so in the relative degree of its development do men vary more widely than in their intellectual endowments, strictly so called. Thus, to refer again to the example of men who have accomplished some great purpose in life, we find that although such men have been by no means invariably distinguished by genius, yet that they have all been remarkable for strength of will. In such men the will was domiuant, subjugating and controlling the passions and instinct. Thus, they were distinguished not so generally by intellectual wealth, as by the earnest and sustained application of the powers at their command.

On the other hand, what pitiable spectacles have been presented by the grandest intellectual powers, when accompanied by what Coleridge, in his wretchedness, described as impotence of the volition! Truly, there is no slavery so abject as that which springs from want of self-control, no victory so fruitful as that which we achieve over ourselves. Thus, those who have been great, who have been successful in accomplishing some high and noble purpose in life, have been remarkable for character rather than intellect. This distinction is an important one. The latter may accomplish great things, but it is the former which secures success in life. Men differ in ability, but infinitely more in conduct; and we are not responsible for the powers we possess, but the use we make of the powers at our command. Resolution, energy, and perseverance, which are but various manifestations of the power of the will, are the qualities which recommend and ensure success; while infirmity of character and feebleness of purpose will mar the fairest prospects and destroy the brightest hopes.

All men covet success. But desire is not effort. There is a vast difference between wishing for

anything, and the endeavour to obtain it. Every man possesses the means of success, if he will only use them. If the consciousness of inferior capacities lead a man (as it should do) to recognise the need of extraordinary efforts, it may become the fulcrum of a lever which will move all things.

But a man may acknowledge all this, and yet refuse to accept the conditions. He declines to pay such a price for the result; he fails, not from want of faith, but of resolution. In such a case, let him not accuse any but himself. Let him not cast it upon circumstances, for the most unpropitious have by his fellows been overcome; let him not charge it upon opportunities, for other men have made them.

The difficulty does not lie in our ignorance—we can all tell what is good and great; it is in the struggle to *do* well that the great battle of life is fought.

Gentlemen,—Life is before you. If Anticipation, the enchantress of youth, could, by the touch of her bewitching wand, disclose to your view the future of your lives; could you, as you are, see what you might become,—then there need be no misgiving of the course you would pursue. But what is now all mist and shadow, Time, the great magician, will soon—too soon—reveal; so soon, that before this Session shall have passed, it may not be impossible to discern the destiny of many amongst you. Your choice is still free, but you have no hours to spare. Though that alone were not inglorious, there are far higher motives to industry than mere worldly advancement. Industry will ensure knowledge, and knowledge is excellent for its own sake. The knowledge that you will acquire is most excellent and most useful,—most useful ,to yourselves, for it will, if rightly employed, enlarge every faculty, exalt the understanding, and ennoble your whole mind; nay, more, the study of the last of Nature's works should teach the truest wisdom, for this transient structure tells, in every change it undergoes, of an Elysium for the spirit it enshrines; and lastly, though not least, most useful to others, for the aim and end of your work is to do good, "to give a true account of your gift for the benefit and use of man."

All is before you. Difficulties and disappointments you must inevitably encounter. They may dishearten you a while, but they cannot destroy you. There are no conditions so hard, no circumstances so opposed, that they will not yield to the labour which overcomes all things.

Work is before you. Independently of all reward, whatever it may be—apart from the result, it is our duty. This should be enough for us. No matter how far he may be removed from the necessity of labour, no man can be at once idle and virtuous. Industry is essential to the happiness of the life which now is. In the present time there can be no real pleasure apart from it, and the retrospect of a life well spent is the sole means of securing peace when we most need it. The faint and obscure traces of Truth which we may here discern are indeed but the shadows of revelations to come. Yet, if now we can see only through a glass darkly, hereafter we shall be face to face. If now we are permitted to know only in part, then shall we know even as also we shall be known.

ST THOMAS'S.

The Introductory Address at this hospital was delivered by R. D. GRAINGER, Esq., F.R.S., to a very large audience. He commenced by remarking that these annual reunions were often regarded as mere matters of form demanded by custom, but intrinsically valueless. He could not, however, in any degree accede to that view, and he should be sorry that their incipient students should enter upon the cultivation of so divine a science as that of medicine with the feeling that aught connected with it could be trite or common-place. Medicine was not what the general public (who, unhappily for themselves, knew so little of the true scope and bearing of the profession) conceived it to be—the bare observation of disease and the application of remedies. On the contrary, it embraced a whole circle of the most deeply interesting sciences, of which it was the very sum and substance. Mr Grainger proceeded as follows:—"As the present is the last occasion on which I shall address you in the capacity of teacher, I am anxious to submit some remarks on the fundamental nature of organised bodies and the forces acting on them, feeling assured that even with those who are commencing their studies I shall best consult their ultimate advantage if I can succeed in conveying to them some right and clear perceptions as to the essential character of that living mechanism, the disturbance of which it is the one object of medicine to prevent, if that be possible; to rectify it if it has actually occurred. Such an inquiry will, moreover, not be misplaced, since even in the present day the prevailing notions concerning the nature of those forces upon which life and organisation depend are, as it seems to me, fundamentally erroneous. But, *in limine*, I must beg you plainly to understand that what I am about to submit to your judgment has reference solely to the phenomena of the mere organic and animal life, to the actions of the body alone—to that life which man shares in common with a cabbage and a worm; that it has no relation whatever to the conscious existence, and still less to the spiritual—to the soul—which, as we are taught by the Word of God himself, and only in a less degree by the researches of all science rightly interpreted, is an entity perfect in itself, and distinct from that earthly tabernacle in which it is now imprisoned; that, in fine, the body is formed out of the dust of the ground, into which the Lord God breathed the breath of life, when man became a living soul. With this all-essential restriction, I conceive it may be assumed, in strict keeping with inductive philosophy, that as the living body is admittedly composed of the common elements of matter; that as those elements are in most organic substances known to be combined in strict accordance with the laws of chemical affinity; that as in a multitude of instances, to which the exact science of the present day is continually adding, it is recognised by all that the actions of the living body are either chemical or physical in their character, so in reality is proved the operation of physical forces, and that all the so-called vital actions are as essentially dependent upon these same powers. Views like these, as many now present well know, have at various periods been enunciated with greater or less precision, but nothing has been firmly established; whilst, on the other hand, volumes have been written to prove that the phenomena of living bodies are altogether peculiar and depending on forces to which there is nothing analogous in common matter. Even in the case of those processes which obviously are closely allied to chemical and physical phenomena, physiologists spoke of them as altogether peculiar and vital. There were so many of those terms—such as animal heat, vital elasticity, the chemistry of life, and so forth—which, violating in themselves the sublime unity displayed in the primary forces of nature, were coined with the express object of teaching that the living actions were altogether *sui generis*. It is true that no very clear ideas were attached to such expressions, for the sufficient reason that they were, as we can now perceive, entirely fallacious; but whilst they prevailed, they involved many of the prime questions of physiology in the same hopeless obscurity as would be caused in astronomy if it were admitted that there were two distinct kinds of attraction or two laws of gravitation. In considering this question we must recollect that only the most universal principles are concerned; whereas it seems to me many of the prevailing opinions have reference merely to secondary properties and phenomena, which have no significance to the natural philosopher or the physiologist. Form, magnitude, colour, and like sensible qualities, are all subordinate points; indeed, one of the very first lessons the student has to learn is to discipline the senses, which by themselves are liable constantly to mislead, since in nature the obvious is rarely the true. Who by any sensuous observation could ascertain that the ultimate particles of matter, which are infinitely minute, never actually touch each other even in the densest substances, as a mass of flint, or a plate of polished steel—nay, that no amount of force can compel them to come into contact, since all bodies, even water, are compressible; that the ultimate particles are thus free to move among themselves in the most solid bodies, and may—even do—incessantly, like the earth itself, as De la Rive infers in his theory of electricity. Similar illustrations abound in organic matter. Thus the blood may be scarlet, as it is in the vertebrata, or colourless, as in the numberless tribes of invertebrate animals, insects, mollusca, and so forth; but it is essentially the same fluid; and so the breast-bone may have a narrow projecting keel, as in birds, or be flat and expanded, as in the chelonia, and yet present exactly the same typical parts in both. And so in the case of the forces implicated respectively in organic and organised bodies: it may in the present state of knowledge be very difficult to demonstrate their ultimate identity. Nor need this be a matter of surprise when we recollect how very recently the intimate relations of the several physical forces themselves have been discovered by such researches as those of Oersted, Faraday, and Graham. Chemical force, electricity, magnetism, caloric, light, act and re-act on each other in the mode signified by the term correlation, and are probably, as many profound philosophers suppose, only different manifestations of one universal, all-pervading force. To proceed to the organic forces, such as the nervous and the muscular. We perceive a current of the former passing through the motor nerve, crossing the sarcodes matter at right angles, as the latest as well as earlier observations prove, like the electric and magnetic currents moving in the direction of the equator and poles of the earth, and thereby evoking the muscular force, whilst again there passes out of the living muscle a force which, as in the experiments of Matteucci, excites the nervous force. We know, further, from the same penetrating observer, that this muscular current carried along the coils of the galvanometer, induces the same kind of deflection of the magnetic needle as electricity. It is, moreover, most remarkable and instructive, as my lamented friend Dr Todd pointed out, that although this muscular current is thus so closely allied to electricity, it is so far distinguished from it that it is arrested by conductors, as when a thin film of gold is wrapped round the living muscle, whilst it readily traverses non-conductors, phenomena the very counterpart of what Professor Muller pointed out years ago in regard to the nervous and electric forces. Now, although this may seem to indicate an ultimate and essential difference between the electric and muscular currents, it presents the very same condition of things as that expressed by the term correlation of forces. The mere fact of the existence of differences in physical and vital forces is therefore not in itself sufficient to demonstrate that there is a primary essential distinction between them. And thus truth being recognised and kept in view, we shall be in a better position to weigh the existing opinions on this question. In the case of animals the error which almost universally prevails, and is, I believe, more misleading than any other, is the idea that their actions exhibit such marks of intelligence, and are so exquisitely adapted to ensure the designed end that they cannot be referred to the operation of physical forces. To show that this is no mere allegation on my part, it is not necessary to go back to the ancient hypotheses, to the Anima of Stahl, or to the Archæus of Van Helmont. It will suffice to refer to the views of modern physicians and surgeons. Thus, an author most justly esteemed, the late Dr Prout, seeing in every part of the animal economy unequivocal marks of the adaptation of means to ends, infers that in the various parts of every organic body there exist intelligent agents 'superior to and capable of controlling and directing the forces operating on inorganic matter,' and thereby affecting the vital phenomena. And so in respect to pathology. I remember conversing with a very eminent surgeon who, whilst admitting the existence of the endosmotic force of Dutrochet, urged that no such mere physical power could account for the separation of a mortified part from the living body, such as the detachment of the sequestrum in a diseased bone, because this process gave evidence of perfect design. These erroneous opinions, still prevailing among so many medical men, renders it necessary for the student always to keep in view the truth recognised by the great teachers of physical science, that the whole of nature is full of design and of intelligent actions, produced by agents in themselves unintelligent. What, in fact, in its widest acceptation, is law but the operation of the

Divine Will so controlling the forces of the universe as to produce a pre-ordained, specific, and intelligible result? No writer that I know has set forth this great principle more forcibly than our great exemplar, Harvey, who, contending against the very error we have indicated, is at pains to show that the common elements of matter and the forces connected with them—air, water, fire, the ocean, the very winds which waft navies to either India, nay, even round the globe, and often by opposite courses—are, as he so eloquently expresses it, subservient to the will of the supreme, intelligent, and eternal God; thereby surpassing their own powers, producing the exquisite order, harmony, and design, which are evinced as plainly in the globe we inhabit as in the most elaborate and perfect animal. To pursue and illustrate this great argument, we may ask why are the lofty Andes placed at the extreme western verge of South America, if their position be not in foreseen and strict relation to the direction of the trade-winds, those grand water-carriers by which this continent is fertilised? Had this range of mountains been placed in the eastern border, they would have intercepted, as by a wall, the aqueous vapour borne from the Atlantic, and the vast forests and valleys now watered by the largest of all rivers, the Maranon, and redundant with vegetable and animal life, would have been converted into an arid, burning plain, identical with the rainless region of Peru, where a second kind of Sahara being produced, the lama, the representative of the camel in the new world, and a few other animals, find a scanty, but yet to them sufficient existence. One other instance may be permitted, since it is more individually connected with physiology—the rapid ascension into the highest strata of the atmosphere of the heavy carbonic acid generated by respiration, combustion, and putrefaction—a phenomenon in which one physical power, diffusion, overcomes another, gravitation, both being but modifications of one force, attraction, with the obvious intention of removing a poisonous gas from the immediate surface of the earth, which, if left alone to the power of ordinary attraction, would have rendered animal existence impossible." Mr Grainger next combated the erroneous argument in support of special vital forces, that organic matters are altogether peculiar in their chemical constitution, attributable to what is often termed the chemistry of life, and that nothing like them is found in inorganic matter; and also another prevalent opinion, which is considered by many distinguished physiologists as embodying the most important proof of the existence of a vital principle, and which relates to the internal arrangement of the parts of which organised structures and inorganic bodies are respectively composed. There could be no doubt that in this, and perhaps in other countries, the overruling influence of the Hunterian doctrine of a vital principle had most powerfully tended to the propagation of the erroneous views which had been touched upon. He need not point out to many of his auditors that the great instances adduced by Hunter in support of his theory of life, and to which he recurred again and again in his writings, relate to the cause of the coagulation of the blood, the resistance of a freshly-laid egg to freezing, and the power which enables the stomach during life to resist the solvent action of the gastric juice. In each of these instances Hunter, as it is well known, attributed the phenomena to the defensive power of life, to his vital principle, and in the then state of knowledge it was scarcely possible to draw any other inference, so plain appeared to be the evidence and so inevitable the conclusion. It was, however, very remarkable and instructive that modern science, which in such a multitude of instances had enabled them to distinguish the real from the apparent, had demonstrated the fallacy of all these instances. Thus, Dr Richardson has shown that the coagulation of the liquid fibrin was owing to the loss of its ammonia, whilst Mr Paget, by his interesting experiments, had proved that the fresh egg of the hen remained unfrozen when exposed to a temperature several degrees below 32 degrees, not because it was alive, but because the mechanical disposition of the albumen, as in the similar instance of the leaf of a vegetable, prevented the watery particles running together into crystals of ice. From these and similar considerations, he was satisfied they might rightly conclude that, save and except the sentient and truly living soul, every part and organ of the human body was formed of the common elements of matter, combined by pure physical and chemical forces, and acting exclusively in obedience to those powers. (Loud cheers.)

LONDON.

The Inaugural Address at the London Hospital Medical School was delivered by Dr Barnes, Fellow of the Royal College of Physicians, assistant obstetric physician to the hospital. He said he proposed to offer to the students some general remarks upon the relations of medicine to society at large, in order that they might more clearly appreciate the position they were about to occupy, and to be led, he trusted, seeing the height and extent of the mission on which they had embarked, to pursue these studies in a liberal and generous spirit. Their special object was the cultivation of physical and biological science. These departments of knowledge were largely indebted for their existence and development to the labours of medical practitioners. They constituted the basis of medical knowledge. They at the same time afforded the student an inexhaustible exercise in training his powers of observing and judging. It was very true that the study of these sciences of matter and of life did not exclusively belong to the domain of medicine. But it was also true that the most ardent and the most successful promoters of these sciences had always been found amongst medical men. Their art consisted in the application of a knowledge of life and of the influences of matter upon life. If they began to study the nature, or rather the phenomena and laws of life in man alone, they were soon irresistibly attracted to extend their observation to other creatures. As they proceeded in this study, the beauty, and order, and correlation of the organic and inorganic worlds opened more and more upon them; their knowledge of each animal or plant became more perfect and luminous, through the constantly multiplying beams of intelligence reflected at every step; and being so constantly reminded that their professional duties called upon them to make all their acquaintance with the vast field of biology subservient to the benefit of man, they enjoyed a sure and a never-failing stimulus. Their study was truth—the glorious truth of nature, as revealed in the creation. Their aim was beneficence—to allay misery, to assuage suffering, to advance the physical and moral well-being of mankind. Viewed as an educational agent, as a means for cultivating the highest and best faculties with which a man was endowed, the study of medicine, and the collateral sciences was unrivalled in the whole range of human knowledge. That undeviating pursuit of truth it was which they might claim as the peculiar attribute of their profession. When they looked upon a suffering patient, their first and constant thought was to penetrate the mystery of his affliction, to ascertain what it was that traversed and disturbed the course of health. Their object was to seize and comprehend the effort and action of Nature in combating the influences under which she was labouring. They sought to aid her in the conflict—they were compelled to observe and to follow her laws. If they deviated from this path—if, losing sight of the beacon of observation, they chased the *ignis fatuus* of speculation, they would surely miss their aim and fail to benefit their patient. It would be hard to name any other profession whose pursuit is truth undefiled, and harder still to find one whose pursuit is truth for the sake of beneficence. After some remarks showing the inferiority of religion, law, the study of history, &c., in this respect, Dr Barnes continued:—In natural science we are not reduced to choose between fallacious evidence and speculation. When we doubt, we turn at once to the ever-open book of Nature; we consult at first hand testimony that may be cross-examined and verified by all. For example, if two anatomists differ in their description of an organ, a third anatomist does not waste his time in weighing and balancing the statements of the combatants; he proceeds at once, instructed by their experience, to re-examine at the original source. And here let me break for a moment to exhort you to follow this plan. When you read one account of a disease in one book, and a different one in another, do not use one book as evidence to condemn the other. Both may be wrong. Search at the common source for yourselves. Never yield to the temptations of controversy; for notwithstanding our immeasurable advantage in having the standard of Nature to appeal to in our disputes, we have controversialists amongst us. If you think you have discovered some new fact or law, and your position is attacked, as it is pretty sure to be, do not reply or defend it by arguments or pleadings. Be assured that you and your opponent will never settle the matter by talking or writing; but humbly and patiently question Nature again, and appeal to her testimony whether it be for you or against you. Turn your eyes for a moment to the hospital close by. The first patient—sick with fever or consumption—is a victim to malaria rising up from the sewage sodden soil, or engendered in his cramped or overshadowed dwelling, never purified by the living atmosphere or the rays of the sun. The next is a man whose limbs are fractured, or who has sustained some other injury, which benevolence, directed by science, might have averted. Further on is one whose energies are destroyed, whose mind is debased, by indulgence in those accursed drinks whose use is abuse, whose purity is foulness, to adulterate which is a superfluous or impossible fraud. These are amongst the evils we have to combat with in civil life. From this scene the mind follows the surgeon to the field of battle. Here he has to avert or to quell the diseases that spring from ignorance and neglect, as well as to repair the injuries inflicted by the destructive engines of war. Or, when we are helpless to save, when the devilish ingenuity or ferocity of generals have done their work too well, when we contemplate the slaughter of a Solferino, and might despair of the usefulness of our art, we may remember, with rekindling pride, the great, the Promethean gift of Jenner, that has more power to reproduce than war has to destroy. With regard to the mode of study, the Lecturer observed: I will now only advert to a few points of general importance. First of all, let me impress upon you the paramount necessity of becoming good practical anatomists. No amount of reading, no attendance upon lectures, no gazing at plates or diagrams, will compensate for the neglect of dissection. I am sure my surgical friends will bear me out, when I tell you that the constant practice of dissection is not less necessary as a means of familiarising yourselves with the structures whose injuries you will be called upon to repair, than as a means of mechanical education, of giving precision and dexterity to that instrument from which the surgeon derives his name. And as for the application of anatomy to the practice of medicine, I need but remind you that it is only the quack who pretends to cure the human mechanism without knowing the structures that compose it. Connected with this point, I will further urge upon you to frequent the dead-house. Thus passing from the study of healthy structures to the examination of them when altered by injury or disease, you will acquire the more precise ideas of pathology, and be in a position to understand the natural history of disease in the living. Here, also, I would advise you to acquire the art of opening dead bodies with neatness and accuracy. In practice, you will often be called upon to perform this operation, either to satisfy the anxiety of friends as to the cause of death, to aid in judicial investigations, or for the advancement of medical knowledge. I assure you it is an art, one which you will certainly appreciate hereafter if you possess it; and you will as certainly regret your deficiency if you possess it not. The curricula and examinations of the licensing boards are now so definite and extensive, that it is inexpedient to advise any marked departure from the order of study prescribed. On the whole, it is the wisest course to take up the various subjects in the order indicated by the successive examinations. But I cannot omit to state my own conviction that you ought not to postpone attendance in the wards of the hospital. You cannot too early begin the exercise and training of your powers of observation. At first you may understand but little of what lies before you; but gradually you will see more and more distinctly. Where at first you will receive little beyond the confused image of rows of beds occupied by sick persons, you will soon, by the daily practice of analysis, and by attending to the remarks of your

teachers, arrive at the power of resolving this confused image into its elementary constituents. Each ward, each bed, will present to your mind a vivid picture full of instructive details. One bed will be associated with the picture of a man of yellow aspect, dusky lips, propped up in a posture half reclined, half sitting, breathing with short and frequent inspirations; and this picture you will fill up with all the other symptoms of pneumonia, the causes that produced the disease, and the treatment which relieved it. Another bed will recall to your mind another pathological history; and thus you will go on storing up facts, extending your intimacy with disease, and invigorating your powers of observation. Your practical labours in the dissecting-room, in the dead-house, and in the laboratory, will every day be throwing new and clearer beams of light upon your clinical studies. Every day you will experience something of that puro and intense delight which excited the Ευρηκα of Archimedes when he discovered the law of specific gravity. And, if you study in the right spirit of humility and perseverance, you will every day open up new vistas of fresh inquiries to be prosecuted, of discoveries to be made. Acquisition and anticipation will accompany you, will cheer and illuminate your path. Such is the Profession you aspire to join—this is the mission on which you are embarked. It is no mean privilege you seek. You may not find wealth, but with earnestness and industry you will surely find happiness and competency. Our fleets, our armies, and our colonies cover the globe. All find employment for the members of our Profession. The entrance into the public services is now the right of merit, not the appanage of nepotism. Then there is the career of private practice before you. If we have few splendid prizes, if there be but few great fortunes amongst us, so there are but few great reverses. It is one of the immunities which we enjoy to a large extent with the other learned Professions, that we are tolerably sure from those calamities which the errors and misfortunes of others so often entail upon those engaged in commerce. There is, perhaps, hardly any profession in which a man need depend so little for success upon extraneous aid. So long as he enjoys that blessing which it is his aim to dispense to others, the physician approaches most nearly to the Horatian standard of freedom and independence—the man "*in seipso totus teres atque rotundus.*" This, you will say, is the sunny side of the picture. It has no doubt a reverse one—a side not without asperities and angularities. Upon this, however, I think it unmanly and unbecoming to dwell. Success rarely attends the querulous man. No doubt you will all have your difficulties, your disappointments, your days of expectation, and your hours of despondency. In all this, I, more than most men in the Profession, can sympathise. But unalloyed prosperity is not the lot of man, nor is it good for man. The true use of present adversity is to chasten and strengthen the mind—to teach us to look hopefully into the future, not alone of this life, but of the life beyond. Before concluding addresses of this kind, it is customary to offer some words of advice concerning the moral conduct of students. I will spare you this infliction. I take your presence here to-day, as aspirants for reception into the order of Medicine, as a pledge that your behaviour will be that which becomes Medical practitioners and gentlemen. We shall, I am well assured, all work steadily together for the credit of this hospital and school, for the honour of our Profession, for the advancement of knowledge and the welfare of mankind. Is any further incitement needed to prompt to a life of labour and self-denial? Another, and another still, is not wanting. Reputation, present and perennial, is a spur to every generous mind. It is not given to all to fill a niche in the Walhalla of science; but every man who does his duty earnestly as a Medical practitioner, in howsoever modest a sphere, will assuredly leave behind him a name that will be repeated with affection and esteem—one, perhaps, that will fill a large space in the cherished traditions of the country side. Join, then, with me in the hope, hallowed by the greatest poet of that country which for ages has been the nursery of generous thoughts and noble words, and which now again is the theatre of heroic deeds:—

"Di non perda vita
Tra coloro, che questo tempo chiameranno antico."

GUY'S.

Dr Wilks, who delivered the Introductory Address at this medical school, commenced by alluding to the advantages offered by Guy's Hospital for the purposes of medical study, and inculcated the necessity for students to begin to work in earnest, assuring them of the fact that just as a man sows so does he reap, and especially of this, that if a man fits himself for any position in life the opportunity for filling that position will soon arrive. Dr Wilks alluded to the decease of their senior physician, who had died since they last met, and spoke of him as one of the brightest ornaments who had ever adorned Guy's Hospital. Afterwards he went into some particulars respecting what he believed to be the true meaning of the word "practical"—a word which was constantly enforced on students, and which they often interpreted into an absence of any enlarged culture of the mind, or even into an ignorance of the allied arts and sciences, understanding by the expression "a practical man," he who can treat disease according to the method of the schools, and who knows no more. The Lecturer insisted that, at the present day, since the discovery of the correlation of all natural phenomena, it behoved the doctor to look around him and draw instruction from every branch of science, and even from the affairs of mankind generally, for that those only who have a wide range of observation and thought can hope to elevate their respective professions. "For example," he said, "I take up Dawson's well-known treatise and discover the difficulty which exists, both in the animal and vegetable kingdom, in defining species, and how all created nature has, as it were, a tendency to run together. The opinions there expressed only tend to corroborate my own views, long maintained, with respect to disease, that the so-called typical affections of which we speak are to a certain extent artificial, or that we select certain similar examples of maladies to enable us to apply names to what in our ignorance we choose to call types. The student soon finds for himself that those admirable models of cutaneous diseases in yon museums are but representatives of the more characteristic eruptions, while in practice he knows that he meets with them in every variety and combination. I might illustrate what I mean of the relation of one subject to another in fifty other ways, but another example will suffice, and has often pressed itself upon me with considerable force—that is, that what is true of man individually and of man in the aggregate is true also as regards the morbid manifestations of his being. When we look around into the political world, and see this sudden outbreak of its peoples, or that unexpected revolution, it wants but a moment's consideration to perceive that these are but the outbursts of some long pent-up passions, just as the explosion of the boiler is the result of a long-continued undue pressure of its steam, or the explosion of the mine by the slow burning of the match. In the same way, if we look to individuals we do not discover that the man who has been eminent for his respectability, though unexpectedly discovered dishonest, has therefore for only a limited period followed a course of roguery. From this contemplation of man in general I see a striking resemblance in his corporeal operations. I see, in fact, that the most important changes in the body are of a chronic kind. Just as in history the great revolutions may figure as the most remarkable events, yet in philosophy, if their slow beginnings can be written, so in the same way, although our best books may treat of the acute forms of disease as the types, yet a more profound consideration of the subject will, I think, show that the more chronic or slower changes are those to which we should rather give our attention, and that so far from chronic disease succeeding the acute, as has usually been taught, the contrary is nearer the truth. I need scarcely illustrate my meaning by alluding to the sudden deaths arising from apoplexy or rupture of the heart; for, unexpected though they be, we know that they are but the consequence of long-continued changes in the blood-vessels in the one case, and of equal chronic changes in the muscular tissue in the other case." Dr Wilks then spoke on the subject of specialities in medicine, and they received his most decided opposition. He considered that the body was so fearfully and wonderfully made, that it was impossible to treat one organ separately; and as regarded any additional knowledge of disease which was said to be obtained by the attention being directed to any particular form of malady, he much doubted if this was the case, since diseased conditions were so commingled that they could not be isolated; and taking cancer as an example, the selection of cases of this affection, as it attacks the external part of the body only, and isolating it from other morbid conditions from which it has no actual line of separation, appeared to Dr Wilks to be the very best method for remaining utterly ignorant of its nature. He was sorry to think that special hospitals were established for interested motives, and he spoke of the degraded position in which the medical man placed himself who was always begging for his charity and advertising his cures in the newspapers. That the speciality system, however, was not a novel one, was seen by a quotation from one of Goldsmith's admirable essays, and in which he very properly holds it up to ridicule:—"In other countries the physician pretends to cure diseases in the lump. The same doctor who combats the gout in the toe shall pretend to prescribe for a pain in the head; and he who at one time cures a consumption, shall at another give drugs for a dropsy. How absurd and ridiculous! This is being a mere Jack of all trades. Is the animal machine less complicated than a brass pin? Not less than ten different hands are required to make a brass pin, and shall the body be set right by one single operator? The English are sensible of this force of reasoning. They have one doctor for the eyes; another for the toes; they have their sciatic doctors and inoculating doctors; they have one doctor who is modestly content with securing them from bug-bites, and 500 who prescribe for the bite of mad dogs." Dr Wilks thought that the profession lay open to this ridicule, and that, therefore, it was time for its members to consider seriously how by any such methods of practice they were imitating the charlatan, and really obscuring the boundary which had been hitherto so well marked between them. He considered that the great hope of the regeneration of the profession lay in the promised connection with the College of Physicians, and thus its necessary severance from the Apothecaries' Company; for it was his strong conviction that a profession and a trade having been so long associated together in the public mind had been fraught with the greatest evil. It had appeared, indeed, as if a druggist's shop had constituted the very basis of medicine, and that the Pharmacopœia, or a particular method of physic-giving, formed the foundation of the art. Nothing could be more erroneous than such an idea, for he believed that if Guy's Hospital dispensary was destroyed, their wards would still be filled with patients, to whom great good could be done without any medicines, which enlightened physicians considered now-a-days to be only ancillary. After some further remarks, the Lecturer concluded by inculcating the importance of a moral and religious culture.

The address was listened to throughout with marked attention, and Dr Wilks was loudly applauded by the students.

WESTMINSTER.

Mr Power commenced his lecture by showing the object of our Professional education to be two-fold,—the acquirement of technical knowledge, and a process of mental training or discipline. By constant practice, any single faculty of the mind may be extraordinarily developed; but this generally occurs at the expense of others; whereas the true aim of education is to cultivate equally the various powers, and to enable the mind to concentrate them upon whatever subject is placed before it. The preliminary studies of the Medical Profession singularly various and interesting, and have close relation with that which is the main object of our study, Life. The importance of chemistry, the interest that attaches to it from its antiquity; how the necromancy and alchemy of the middle ages laid the foundations of all the exact chemical knowledge of the present day, and how large a field still remains open in organic chemistry. The value of a knowledge of the vegetable and animal kingdoms, in order that we may rightly enter upon the study of Life, for those

structures and laws which attain such high complexity in the higher animals are then seen in the simplest forms and operation. The pleasure which results from a knowledge of these sciences. How coincidently with these anatomy and physiology must be studied; the necessity of constant and indefatigable labour in their acquirement; their relations to the study of disease. How disease must be studied, not only in the living, but in the dead: in the living, that we may discern the distinguishing characters of the same disease under many varying circumstances; in the dead, that we may see the extremest effects of disease, and knowing the results, may recognise the value of early attention to departures from health. Then, as regards the mental discipline, the importance of habits of observation; examples of Galileo, Franklin, Jenner; the difficulty of correct observation. The necessity, not only of correctly observing, but of reasoning correctly upon observation. Finally, the noble ends and aims of our Profession; how it brings us into relation with all classes of the community, and how our varied knowledge may exercise upon all a powerful influence for good.

KING'S COLLEGE.

Dr JOHNSON, of Savile row, delivered the Introductory Lecture to the students in connection with this college and hospital. After some introductory remarks, the Lecturer went on to say—"And now, before I proceed further, let me revert for a moment to the mournful event which lately cast so deep a gloom over this college in particular, but which also excited a very general lament throughout the kingdom—I mean the death of Dr Todd. You are all aware of the circumstances of his decease, in the midst of a career of almost unexampled prosperity and usefulness. I need not dwell upon the painful details, but I feel that I should be guilty of a serious omission both of duty and affection were I not upon this occasion to allude to some of the many and great benefits which our lamented friend was the means of conferring upon the medical school of King's College. In the first place, then, he was the founder of our hospital. Dr Todd, having been appointed professor of physiology in the year 1836, soon saw the vital importance of establishing a clinical hospital in connection with the college. To his clear sense of the need, and to his success in obtaining the sympathy and the aid of very zealous and able fellow-workers with him, we owe it that in the spring of the year 1840 clinical instruction commenced in that old building, now soon to be entirely replaced by the more commodious and imposing structure which is rapidly approaching completion." Dr Johnson went on to say that Dr Todd was, with the late Bishop of London, the originator of St John's House Training Institution for Nurses. This institution supplied the hospital with a very efficient staff of nurses and lady sisters, and the hospital in its turn afforded to St John's House the means of training its nurses, many of whom were annually sent out to private patients in all parts of the country. Another foundation which had exerted an important influence upon the college and upon medical education in general was that of medical scholarships. These were first established in King's College, and their establishment originated with Dr Todd. The Warneford scholarships, which were intended to encourage an extended preliminary education amongst students preparing for the medical profession, were always considered by Dr Todd to be in the highest degree beneficial. Another important element in the arrangements for medical education in that college, which originated with Dr Todd, was the establishment of the office of medical tutor. The Lecturer continued—"I have referred to some of the results of Dr Todd's energy and influence while he was working amongst us here. But it was as a teacher of physiology and clinical medicine that he conferred the greatest benefit upon his pupils and upon the college. Few teachers have ever possessed in an equal degree the power of exciting the interest and of winning the confidence and the affection of their pupils; few men have ever exerted themselves so much to promote the welfare of those whom they have taught; few teachers have had the proud satisfaction of seeing so large a number of their pupils pursuing a career of usefulness and distinction. This is not the time or place for the discussion of any disputed points in Dr Todd's therapeutical doctrines. Suffice it to say that those who by the bedside had enjoyed the fullest opportunity for noting the accuracy of his observation, the soundness of his judgment, and the remarkable success of his treatment, were the most ready to declare that his great fame as a physician rested upon a solid basis of true desert.

'He was a man, take him for all in all,
We shall not look upon his like again.'

I must not omit to mention that Mrs Todd, with a munificence truly akin to that which characterised her departed husband, has presented to the hospital, for the use of the present and all future generations of students, Dr Todd's large and valuable medical library." The Lecturer then proceeded to address himself more particularly to those who were about to commence their professional studies. He remarked—"The educational discipline which you have already received has had for its object to give pliancy to the faculties, to render the perception vivid, the attention alert, the imagination inventive, the memory full, the judgment just, the reason searching. You are now to bring your trained and disciplined faculties to the study of those deeply interesting sciences which are subservient to the practice of medicine and surgery. Every good habit which you have acquired, whether of self-denial, of steady persevering industry, of method, and order, and punctuality, or of obedience to authority, will serve you in good stead during the period of your pupilage here." The Lecturer then endeavoured to excite in the minds of his younger hearers some adequate appreciation of their happy position and prospects as students commencing their academic career, reminding them that they had youth, health, energy, and elasticity of mind to carry them onwards,—that they were free from the distressing cares of life and the harassing engagements of business, and had before them three or four years for the uninterrupted study of some of the most interesting subjects which have ever engaged the mind of man. The curriculum of their studies being prescribed by authority, they had but to work heartily and honestly at each subject as it came before them in their academic course. They would then find that day by day, while their interest in their studies increased, the difficulties and the obscurities would diminish. By the act of matriculation they had become members of a college in which, for some years to come, they would be subject to the wholesome and humanising influences of a well-ordered discipline—a discipline to which all, whether professors or pupils, were expected to conform, and to which, as it was their duty, so it should be their happiness to render a loyal and cheerful obedience. The Lecturer particularly insisted upon the importance of a regular and diligent attendance in the wards of the hospital. "There," he said, "you have the actual presence of that with which it will be the business of your life to deal—disease itself in all its varieties and stages. There, and there only may you learn by actual practice to recognise and to interpret the physical signs and the functional symptoms of disease, to trace it through its various phases to the final result in recovery or death, and in the latter case you may have the opportunity to note the structural changes which have resulted from disease triumphing over treatment—an opportunity which you ought never to miss." The Lecturer referred to the practical examination by the bedside, to which candidates for a degree at the University of London are now subjected, as giving a wholesome stimulus to clinical study. He warned the younger students that on being released from the restraints of school, and the watchful control of parents and guardians, they would in this great metropolis be exposed to peculiar dangers and temptations. He exhorted them to a faithful discharge of their duty, and told them that one of the best safeguards against evil would be found in a steady persevering industry. Their success hereafter would depend greatly upon character. Their future patients would look not only for professional skill, but they would require in those whom they admitted to their confidence the high principles and motives of Christian gentlemen. In conclusion, the Lecturer said—"The Profession which you have chosen, gentlemen, is one in which you may find ample scope and opportunity for the exercise of the highest attainments of the intellect and for the greatest of Christian graces. May you never be tempted to forget the true end and dignity of your calling! That which Lord Bacon said of all knowledge is in an especial manner applicable to the science and skill which it will be the business of your lives to acquire and to use—namely, that it 'is not a couch whereupon to rest a searching and restless spirit, or a terrace for a wandering and variable mind to walk up and down with a fair prospect, or a tower of state for a proud mind to raise itself upon, or a fort or commanding ground for strife and contention, or a shop for profit or sale; but a rich storehouse for the glory of the Creator and the relief of man's estate.'"

Dr Johnson was loudly cheered during the course of his lecture, as were the other professors who were present.

ST GEORGE'S.

Dr PITMAN delivered his Inaugural Address. He remarked that the occasion which had called them together, namely, the commencement of another Medical year, presented a favourable opportunity, of which he gladly availed himself, to offer some suggestions for the guidance of those who were about to commence the study of their Profession. Possibly they might expect that he should in the first place endeavour to solve that difficult problem, "Who is a doctor?" and define how much learning is implied in a diploma, or what amount of professional skill and knowledge is sufficient to justify a claim to that much-coveted prefix. But his purpose was more practical. To describe to them the qualities requisite for profitable study, to advise them as to the employment of their time, to anticipate difficulties, to inspire hope—in fact, to point out how they might obtain sound knowledge, how secure professional reputation and success, and so satisfy the expectation which their friends had formed: these were subjects which appeared to him better adapted for their consideration, as involving questions of the deepest interest to all. The profession which they were about to study was that of physic, in the sense in which that term was generally understood; the art of healing diseases; a pursuit having for its object the attainment of means for prolonging life and for relieving human suffering—one of the noblest occupations in which they could engage. Much, however, depended upon the spirit in which they entered on its study. Dr Pitman having earnestly advised steady and undivided attention on the part of the students, remarked that it was the observation of little things, of events apparently trivial and unnoticed by others, which furnished the medical practitioner with most valuable information; but if they looked without perceiving, or, as the Russian proverb expressed it, "walked through the forest and saw no firewood," many opportunities of acquiring experience and gaining knowledge would be lost upon them. How was it that so much was read and yet so little remembered? Because the attention was not fixed; it became unsteady, wandered away, and became engaged in other occupations, while the eye still travelled on over pages which might as well have been so much blank paper. He impressed upon them the necessity of a constant habit of reviewing the employment of each day. Some appropriate remarks followed on the importance of economising time. Experience would soon prove to them that he who knew the true value of time and the importance of economy in its use, was he who found time apparently for everything,—for punctuality in all the relations of life, for the pleasures of society, for every rational amusement, and who was also the most assiduous and the most successful in the actual pursuit of his profession. And yet how common a thing was it to hear a person excuse himself for the omission of some duty, or for the neglect of some engagement, by saying that he had not time, yet acting probably as if he had an unlimited supply! There appeared to be some persons who had a remarkable power of so arranging their time as to make it available for many things for which others could not find leisure or opportunity. They had an instance of

this faculty strongly marked through life in an ex-Chancellor now living. Many years ago Sir Samuel Romilly was applied to to undertake some business, but having numerous professional engagements, he excused himself by saying that he had not time, adding, "Take it to that fellow Brougham; he finds time for everything." A distinguished writer of the last century had stated that every person had two examinations,—one which he received from others, and one, more important, which he gave to himself; not that they were distinct in kind, but that they differed in the source whence they were derived. It was not enough that knowledge should be brought by others within their reach, nor was their assistance sufficient to give them its possession; it must be made their own through their own exertions. From whatever source education was received, its aim should be to teach them rather how to think than what to think—rather to improve the mind, so as to enable them to think for themselves, than to load the memory with the thoughts of other men. Much of their time would necessarily be passed at the bedside of patients, making inquiries, comparing one case of disease with another, ascertaining their essential characters and connecting these with the causes on which they depend. Note-book in hand, and recording daily every fact, however trivial it might appear, an accurate knowledge of disease would be acquired, and they would soon accumulate an amount of practical experience which would prove of inestimable service to them in after life. Clinical study, like all other studies, to produce its full advantage, must be pursued with a method—that is, regularly and perseveringly. Students were too much in the habit of desultory attendance in the wards to derive much benefit. They followed one physician or surgeon for a week, watched the cases for that time, and then did the same with another for the same period. The consequence was that no case of disease was carried through by the student, who saw in this way only odds and ends of illness. It was certainly walking the hospitals, but nothing more. It was not study. To become acquainted with disease, they must see it in every stage, in its commencement, progress, treatment, and termination; and the investigation of disease so conducted had a value which no other method could equal. So important was this method of study considered, that every student was required to perform the duties of dresser and clinical assistant; and still further to promote this object, prizes were annually offered to the most diligent and industrious in this department of study. The names of the prizemen were then announced, and the Lecturer concluded with some appropriate remarks on the moral conduct of pupils.

MIDDLESEX.

The Inaugural Address was delivered by Dr CHARLES COOTE. The Lecturer spoke at some length of the high moral tone which should be observed by Medical students, dwelt on the noble incentives to study which their Profession provided, and urged a close attention to the study of anatomy and physiology. At the close of the lecture, a *conversazione* was held in the new buildings connected with the hospital.

UNIVERSITY COLLEGE.

At this hospital the practice of delivering an Inaugural Address has been abandoned, and yesterday's session was opened by a distribution of prizes to successful students of previous terms.

CHARING-CROSS HOSPITAL.

The Introductory Address at this School was delivered by Dr CHOWNE, and was well received by a considerable number of the friends and old pupils of the Hospital.

SUDDEN DEATH OF DR JOSEPH BARRY OF MIDLETON.—We have to announce with great regret the very unexpected death of the above-named gentleman, who for many years enjoyed the esteem of the inhabitants and his professional brethren in the county of Cork. It appears that on the 18th ult., the guard on duty at the Killeagh Station of the Cork and Youghal Railway discovered Dr Barry lying on the seat as if he was asleep. Assistance having been obtained, he was conveyed to the station-house, and medical aid was called in, which, however, unhappily proved unavailing. Dr Barry, it appears, had spent the day at Youghal and bathed in the sea there, and up to the time of his death had enjoyed apparently good health.

THE SPIRIT OF THE PERIODICALS.

The 'Lancet' opens with a continuation of Mr HILTON'S Lectures on *Pain and Rest*. This is followed by an account of a case of *Rupture of the Uterus during Labour*, by Dr E. L. ORMEROD, which we quote:

"The woman from whom this uterus was taken was thirty-six years old, large and well-made, but singularly pale; she had, however, always enjoyed good health. She had borne seven living and five dead children at the full time, and, besides these, had miscarried at the sixth month in the previous year. The first stage of her labours was always very tedious, and increasingly so with each successive labour. She had never suffered from uterine hæmorrhage; it was not known whether she had habitual leucorrhœa, or had ever suffered from syphilis.

"About three months before the fatal issue of this her fourteenth pregnancy, she was suddenly taken with seeming labour pains—with the same symptoms, in fact, as had ended in a miscarriage at the sixth month in the preceding year. These pains continued severe for twenty-four hours, accompanied by the discharge of a large quantity of offensive fluid; they then ceased, and her pregnancy went on, without any further incident, till nearly the full time,—namely, a fortnight before her death. Then it seemed as if labour fairly set in, for from that time she had a constant succession of regular pains, continuing day and night, so as quite to interrupt her sleep. She had an abundant discharge of fluid at the outset, which she supposed to be the waters coming away; and this continued throughout the whole fortnight, only in less quantity.

"However, she was used to matters proceeding very slowly, and did not even send for her nurse till the pains came on with more violence nine hours before her death. Her nurse was with her at nine p.m., and at eleven she sent to tell Mr Fry, her usual attendant, that she should soon want his assistance. She was then lying in bed, very cheerful, and expecting a speedy delivery. Before Mr Fry's arrival, however, a great change had taken place in the patient; for at twelve o'clock he found her collapsed, and, on examination, was unable to ascertain the nature of the presentation. From his former experience of the case he thought that there would be much delay, and, not being well, he left at half-past twelve, requesting Mr Sewell to take charge of the case.

"About twenty minutes, certainly not more, elapsed before Mr Sewell's arrival; but a further change had taken place in the patient in the interval, though still without any sudden violent symptoms. She was then lying on her side, imperfectly conscious and very faint, and all uterine action had ceased. Mr Sewell tried to ascertain the presentation, but could not reach the os uteri; and within a minute or two of his arrival, she had ceased to breathe. There was no external hæmorrhage whatever.

"On examination of the body after death, the peritoneal cavity was found to contain more than five pints of blood, in which lay a full-grown female child placed transversely with its feet to the right. There was no mark on the child by which the nature of the presentation could be determined. The uterus was ruptured straight down the posterior wall from top to bottom, the tear stopping just short of the cervix, and not implicating the vagina at all. The cervix was somewhat everted, so that what seemed to be the os uteri was really part of the canal of the cervix, occupied, in four-fifths of its circumference, by an elastic growth, which was of a somewhat gelatinous appearance, and was studded here and there with little bladdery points. The entrance to the uterus would not allow the passage of a cone of more than one inch and a half diameter. The muscular substance of the uterus was generally soft and flabby, but otherwise healthy-looking. Large flakes of healthy decidual membrane hung from the interior of the uterus. The placenta, which lay loose in the peritoneal cavity, seemed to have been attached on the left side, about halfway up the organ. No corpus luteum distinctly referable to this pregnancy could be found in either ovary. The dimensions of the pelvis were quite normal.

"Portions of the liver and kidneys, of the muscular structure of the heart, and of the uterus all along the line of rupture, were examined, and found free from any traces of fatty degeneration. The uterine muscular fibres about the fundus of the organ were quite healthy; but those taken from the edge of the rupture, near the cervix, did not display the muscular structure as distinctly as those from the fundus. They were smaller, darker, and apparently mixed with fibrous tissue, which connected them closely together, and gave them a woolly look. But there was no fatty degeneration anywhere.

"On vertical section of the mass which grew from the interior of the cervix uteri, the structure had a honeycomb appearance, from a number of irregularly cylindrical cells, distended with a clear mucus, swelling up from the cut surface. The general appearance of the cells was very like that presented on section of a compound ovarian cyst, the white, opaque, fibrous septa contrasting with the transparent contents of the cells; only these cells were arranged parallel to each other, at right angles to the uterine structures, and they were somewhat oval, not radiating and pyriform as in an ovarian tumour. The whole mass was nearly three-quarters of an inch thick, and the bladders, already noticed, on the surface, were the protruding ends of some of these dilated mucous follicles.

"From the cut surface the mucus could be raised with the forceps in distinct masses, which retained the form of the original cells, and were evidently enveloped in a fibrous membrane of extreme delicacy. This membrane was wanting in the mucus which was squeezed out of the cells. In the transparent portion of this nothing could be seen besides a few small nucleated cells, either single or collected in patches; the opaque lines by which it was traversed here and there, were composed of epithelial scales, which were almost entirely of the columnar form, without any ciliæ at their broad ends. No cells leading to a suspicion of malignant disease, no pus or exudation cells, were anywhere to be seen.

"The disease seems to have been simple hypertrophy of the glands of the cervix uteri, accompanied by fibrous degeneration of the adjacent muscular structure. It would be very difficult precisely to fix the origin and order of succession of all these changes in and about the cervix uteri, but it seems most probable that the constant afflux of blood, necessary to maintain so large an abnormal secreting organ as the hypertrophied glandular element grew to, was inconsistent with the normal periodical growth and decay of the muscular tissue hereabouts, and led to the formation of a more permanent structure in its place. The follicular disease was harmless enough in itself, but, incidentally, its constant presence caused, or was accompanied by, a permanent change in the muscular structure, which interfered with the mechanical functions of the part, and thus gave rise to rupture of the organ. It was not the bulk of the tumour which caused the obstruction, but the rigidity of the tissues about the orifice of the womb.

"Apparently, this condition of parts had existed for some years, gradually increasing till what in the first instance had merely delayed the dilatation of the os uteri ultimately impeded this process so effectually that the muscular structure ruptured itself in its fruitless efforts to overcome the resistance. It cannot be inferred that the hypertrophy and distension of the mucous glands of the cervix uteri were the consequence rather than the cause of the protracted labour, for the tumour did not implicate the whole circumference of the cervix, as might have been expected under such circumstances.

"One other point invites examination: At what period did the rupture take place, and how? At eleven p.m. the patient was cheerful, and expecting delivery; at one p.m. she died. No information can be obtained defining the period within which the rupture took place more closely than this. The rupture would seem to have been gradual, for it is inconceivable that an injury of such extent, and accompanied by so much hæmorrhage, should occur suddenly without producing violent and immediately fatal symptoms. I am inclined to the conclusion, which the negative history of the case strongly favours, that the rupture and hæmorrhage were not instantaneous in all their extent, but that the uterus gave way at first only in a single point, and that the lacera-

tion was gradually dilated to its full extent by the passage of the child."

Dr G. Gibb contributes the following article on the *Laryngoscope*:

"Professor Czermak, lately of Pesth, but now of Prague, in Bohemia, paid a short visit to London in the last week of August, and took advantage of the opportunity to demonstrate the use of his laryngoscope at some of the hospitals, and at several private sittings, to many members of our Profession. I spent the evening of the last day of the same month with the Professor, by special appointment, in company with Dr Thudichum, and he favoured me with a comple description of his most valuable instrument, and showed the use of it upon his own person, a brief account of which I thought of sufficient importance and novelty to bring before the readers of the 'Lancet.' I must premise by stating that M. Czermak does not take to himself the credit of having been the first to invent the laryngoscope, for he was fully aware—as, indeed, he states in his work—that Mr Liston had contrived something of the kind in 1840, and more lately M. Garcia (1855). He was not acquainted with Mr Avery's instrument, which has been known to the Profession, as I am informed, for many years. But he has perfected the instrument in every way, and has shown its application in the most satisfactory manner to both physiological and pathological researches. There are many instruments in London which are called Czermak's; some of these were shown to him, and he informed me that they were not his invention, and were widely different in their construction from his own. It is of importance to state this, because any one anxious to use the proper laryngoscope can obtain it from Weiss, in the Strand.

"It consists of a circular mirror, perforated by a round hole in the centre (indeed, like that of the ophthalmoscope, only that its diameter is greater), and a small looking-glass reflector, on a stem and handle, for introduction into the pharynx. The light employed may be either that of the sun, or of a good moderator lamp in a dark room; the latter is always at command. Clear daylight will answer. With a good light, the whole of the pharynx can be illuminated by the aid of this mirror, when the next step is to introduce the small reflector, previously warmed, into the pharynx, gently pressing it against the anterior part of the velum palati and uvula. This proceeding was carried out by M. Czermak in his own throat; and he regulated his movements by the aid of a second reflector, by means of which he himself saw what was being exhibited to the spectator. On his first introducing the small reflector, he repeated the ejaculations, 'Ah, ah!' 'Eh, eh!' continuously, which permitted the epiglottis to be elevated during the expiratory efforts, and a good view of the interior of the glottis, with its vocal cords, to be obtained. The lips of the glottis would occasionally close and expand like a fan, the pivot being situated anteriorly; this, to my mind, is one of the most remarkable and striking features connected with the larynx in its healthy state. This movement was effected by the utterance of the sounds mentioned, and the rapidity with which it was accomplished was truly interesting and remarkable, and affords an idea of what this part of the vocal apparatus undergoes during speaking and singing. He showed me all the different parts of the larynx in a quiescent and active condition, and concluded this part of his demonstration in closing the glottis, by bringing the lateral surfaces of the cords together, and then gliding the arytenoid cartilages forwards into opposition with the base of the epiglottis. This last feature, as he assured me, was one of considerable difficulty to accomplish, and I could perceive that it cost him an effort to do it. It is represented in fig. 10 of the second plate of his work on the Laryngoscope, published this year in Paris.

"Having rested himself for a few minutes, and partaken of a glass of sherry—an example which we all followed, as our own throats were shortly to be inspected,—he reintroduced the reflector, and altered the position of his neck and throat so as to permit of a view down the larynx. With some little arrangement a good posture was gained for the passage of the light downwards, and I saw clearly the rings of the trachea, and afterwards, lower down, the right and left bronchi, with the intermediate septum of a yellowish-white colour, presenting a distinct light object between two apparently circular dark spaces. This is also engraved in his book—fig. 7 of plate 2. I must confess that, familiar as I had been with the idea of the actual passage of a probang so far down by Dr Horace Green of New York—a feat which I knew was quite possible in such experienced hands,—I little dreamt of the possibility of actually being able to *see* thus far down the larynx. There was no disbelieving the evidence of one's senses, but it was some time before I could certainly realize in my mind the fact of having seen, from the mouth, the bifurcation of the trachea in a living and healthy person. Whilst observing all these, I was fascinated with the intense interest of this novel subject, and was only afraid that I was taxing the good-nature of the Professor.

"He now showed me the posterior nares and Eustachian tubes, and all the parts in connection with the former. The posterior edge of the septum of the nose stood out quite distinct, and the posterior terminations of the middle and inferior turbinated bones were well seen. The orifices of the Eustachian tubes presented circular concavities with raised margins, and certainly seemed different from what they are generally described. The upper part of the pharynx was shown by simply introducing a reflector looking upwards, at the same time holding the soft palate downwards and forwards.

"These illustrations were confined solely to the examination of healthy parts; but a great field is opened out, with the aid of the laryngoscope, for the examination of various internal and hidden diseases of the larynx, of which we at present have scarcely any conception. The Professor told me that with its aid he has been enabled to introduce the solid caustic and touch an ulcer within the larynx. If tracheotomy has been performed for laryngeal disease, a reflector can be introduced into the tracheal opening, and a view of the internal disease will be at once afforded from below upwards. Much as the ophthalmoscope has done for hidden and obscure diseases of the eye, it is probable that even more may be expected from the laryngoscope in many terrible, intractable diseases of the larynx. But it appears to me that it is an instrument that cannot be commonly applied, unless by very delicate and steady hands; and it requires a special experience in its use. My own throat was submitted for examination, and the little reflector was delicately and gently applied by M. Czermak in front of the soft palate: I did not feel the slightest uneasiness, although my faucial mucous membrane is irritably sensitive, and I was able to sustain a good, prolonged examination. The Professor declared, however, that I knew how to disport my throat for examination; and he said that he saw the laryngeal structures more distinctly and with greater facility than is his custom. Dr Thudichum was not so fortunate in applying the reflector to my throat, for it rather tickled the uvula, and I felt disposed to cough. After a little practice on myself with this instrument, I feel persuaded that I shall be enabled to demonstrate its use pretty satisfactorily to others.

"There are other peculiarities in connection with the laryngoscope, besides those I have described. It is not necessary, however, that I should do more on the present occasion than to draw attention to the use of this most valuable auxiliary. No one in any way familiar with the delicate structures of the throat should be without it."

M. Claude Bernard's Lectures on *Experimental Pathology* are continued in the 'Medical Times and Gazette.' The present part treats of Muscular Poisons. The Author says:

"That fatal diseases, in a variety of cases, leave behind them no visible marks of their passage, is one of the most singular, and at the same time indubitable, facts which the Medical Sciences have brought to our knowledge: and, as we stated in one of our previous lectures, there exist in this respect two distinct regions in the field of Nosology; some affections being connected with constant lesions, while others are not. Now, the toxic agents to which we have lately called your attention are precisely situated in the same case, and might equally be ranged under two principal divisions,—those which produce evident physical changes in the diseased organs, and those which do not. We have already informed you that several poisons, which destroy life with great rapidity, leave behind them no appreciable alteration of the tissues on which their deadly action has been exerted. In the case of woorara, for instance, we showed you that the moter nerves were entirely paralysed, without exhibiting the slightest modification in their anatomical structure or physical properties. The electro-tonic power, which M. Dubois-Reymond has ascertained to exist in the nerves, still retains, in animals poisoned with this substance, its usual degree of intensity, according to the latest experiments; the galvanic stimulus, however, and the impulse of the will, no longer exert their wonted influence on the locomotive apparatus.

"But if in this case the vital powers are destroyed by a process, the first stage of which lies hidden from our knowledge, a similar property is enjoyed by numerous other poisons, among which strychnia may be selected as an example; a substance, which, as we have already informed you, exclusively confines its action to the sensitive portion of the nervous system, the convulsions which arise from its introduction into the economy being merely the result of reflex action. An essential difference therefore exists between these two poisons, although in both cases the nerves are found to be the seat of disease. As the contrary opinion has lately been maintained by certain observers, who believe the effects produced by these agents to be somewhat analogous, we cannot refrain, notwithstanding the various proofs previously adduced in support of our own views, from mentioning a very simple experiment, which, according to our judgment, decides the question at once. It consists in tying the vessels of the posterior limbs, in two frogs of equal size, without injuring the nerves. The animals are then simultaneously poisoned, by injecting under the skin of the back a solution of woorara in the first case, and of strychnia in the second. The operative proceeding is as follows: A thread being passed under the sacrum, immediately in front of the origin of the lumbar plexus, the whole remaining part of the animal's body is included in a single ligature. All vascular communication being thus intercepted between the hind legs and the anterior portion of the body, the poison exclusively circulates in the trunk and upper limbs, without passing beyond them. Notwithstanding this obstacle, the posterior limbs of the frog poisoned with strychnia enter into convulsions; while in the animal submitted to the action of woorara, voluntary motion exists below the ligature, while absolute paralysis prevails above it. The result obtained in the first case arises from the general influence exerted upon the entire economy by all actions brought to bear upon the sensitive nerves, which acting in their turn upon the spinal chord, produce a universal disturbance of the normal functions, as we have before explained. Such are the results which take place when strychnia is administered; but the effects of woorara being only felt in those parts to which the circulation has conveyed it, are confined to the upper half of the body, when all communication between the hinder limbs and the seat of inoculation has been intercepted. The ultimate results of the experiment afford an additional proof of the difference which exists between these two poisons. After a few minutes have elapsed the subject poisoned with strychnia no longer exhibits the slightest vestige of reflex action in any part of the body; and the motor nerves when galvanized are generally found to have lost the power of acting upon the muscles, particularly when the experiment has been performed during the warmer seasons of the year,—for heat is known to give additional intensity to the effects of poison in cold-blooded animals. But the loss of excitability is not confined to any given point; it extends to all regions of the body, and appears consecutively to the entire abolition of sensibility and reflex motions.

"In animals poisoned with woorara we meet with a very different state of things. The sensitive nerves have everywhere retained their usual properties, while the motor branches are paralysed above the ligature; below this point, voluntary motion persists as long as life remains; and if the animal is thrown into a basin of water, it swims with its posterior limbs, the upper part of the body remaining, of course, entirely motionless. These facts sufficiently prove the vast difference which exists between the action of these two substances upon the nervous system.

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B — The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

THE MEDICAL CIRCULAR.

WEDNESDAY, OCTOBER 3, 1860.

A FEW WORDS TO THE NEW STUDENTS.

The Introductories have been recited, the Schools opened, and the Students have begun their work. The second and third year's men fall into their places without awkwardness; they are familiar with the wards and passages of the Hospital, the Out-Patients' Room and the Accident Ward—are intimate with the Dressers and House-Surgeons, shake hands with a host of old acquaintances, know exactly the right time to be in the way when some great Professor is likely to give a Clinical, or to go round with his class—and the right time, too, to be absent; they drop easily into their old places in the theatre, and recognise the queer inscriptions upon the rails scribbled in ink, or graved with a blunt scalpel; they are familiar with the order of the Lectures, and guess the subjects beforehand; and they know the spare moments between the Lectures when they can do a bit of dissection, and perchance consume a lunch in the intervals of rest, when the back begins to ache and the attention to weary; but the Freshman has no such advantages; to him everything is strange,—the faces, the building, the course of study, and the ways of the place; he is like a man dropped from a balloon in the clouds upon a foreign land; he has no place to go to that he can call his own, no friend to accost with a familiar greeting; nobody seems to heed him, and he is afraid to push himself through the crowd, lest he be thought impertinent: even the talk is strange to him; terms are used of which he has yet to learn the meaning: his heart grows heavy, and, in the loneliness of his feelings, he casts his thoughts back despairingly upon the home he has left, and the habits and affections from which he is severed. In a few days, however, this strangeness will wear off, and as the youth applies to his work, he will find a growing interest in the new world of knowledge which he has begun to explore.

A few words may not be inappropriate upon the relative value of the studies in which he is engaged. With his examinations in view, it will be the paramount duty of the Student to adhere closely to the appointed curriculum, as the best devised order of study which the experience of his teachers has enabled them to arrange. There are also certain records of attendances that operate as checks upon indolence and truancy of disposition. We have, therefore, no fear that a well-disposed Student will neglect a regular attendance at the Lectures, or omit to make one of the crowd that daily "walks the hospital" at the skirts of the great surgical luminary.

But the young Student must know that mere attendance is not enough: without attention, attendance is waste of time. There are many Students who make a point of attending to their Lectures with the utmost regularity, and yet at the end of their term of study are ignorant of almost everything they ought to have acquired. They fancy they know a great deal; but there is nothing arranged in their minds in an orderly manner; they possess no precise knowledge: if they were questioned about the distribution of a certain nerve, they would, in all likelihood, give that of an adjacent artery, being quite in a mist whether their description applied correctly to one or the other. The consequence is, they have a very unpleasant consciousness that they are unfit to submit themselves to an examination; and they accordingly pay Five Pounds to some friend of Students in distress, and they grind! When a man has fallen into a muddle with his Cash Book and Ledger, he calls in an Accountant, who puts all the figures in the right places, and reduces the arithmetical chaos to order: so the grinder methodises the jumble of information in the head of the Student, and gives to it connection, lucidity, and precision.

But if the Student would be attentive to the Lectures, read in the evening the subjects of the morning's dissertation, and, whilst he reads, put the substance of it all in the form of question and answer, he would find that he would not require the grinder's aid. It is very difficult to fix facts or dogmas in the mind, excepting by the catechetical method. A distinct question requires a distinct answer; and thus it is that the gold in our mind is struck into a definite practical coinage, ready for every-day use.

Students are apt to drop into the fault of overlooking the minor accidents and incidents of the Hospital, and to give their attention almost exclusively to the more important diseases and grand operations. Some Students think it quite enough, as a means of acquiring a knowledge of Surgery, to rush into the operating theatre when Fergusson, Skey, or Erichsen holds the knife; and to trace the steps of the operation, if they can see it, and if they can't, to be satisfied with the attempt: all the rest is too unimportant to deserve their attention. This is a great mistake. It may be many years, if ever, before a Practitioner may be called upon to perform the operation of lithotomy; and when the time comes, he will find that he has forgotten much that he thought he had learned, and that, at any rate, he had never learned the wonderful *knack*—impossible to him—which as a Student he so much admired.

There are many small things in Surgery which the Practitioner will be frequently required to do, and which will bring him credit or discredit according to the skill and knowledge he evinces. The treatment of abscesses in all their variety, perineal, mammary, scrofulous, or connected with bone; carbuncles, ulcers of all kinds, phlegmonous erysipelas, varicose veins, hæmorrhoids, fistulæ, obstinate forms of cutaneous disease, passing a catheter, the art of bandaging, dressing wounds of all varieties; the diagnosis of tumours, and the various operative procedures for their removal; the multiplicity of what are termed medical diseases;—all these are matters that come under the daily notice of the General Practitioner, and yet are little attended to by the Student. They are, however, of the greatest importance, since they embrace the principles of Medicine and Surgery as a science, and some of their more recent improvements as an art. Yet young men are apt to think that there is nothing in all these in comparison with an operation for stone, the reduction of a dislocation of the hip-joint, or an amputation of the lower extremity. Do not neglect these last; but attend to the first also. We have known a Surgeon ignorant of the proper mode of dressing a smashed hand, risk the life of his patient; yet he performed the subsequent amputation with due skill. The chief secret of success in ordinary practice is ability in small things. It is very certain that, provided a man have firmness and common sense, the great operations can be performed as well, though not so brilliantly, by a rural Surgeon as by the grander tragedians in our London Hospitals. The success of the cases depends much less upon the operation, *per se*, than upon the subsequent treatment and the hygienic conditions of the patient.

We beg our young friends now entering upon their studies to bear these things in mind: and we would advise them to use their best exertions to obtain the appointments of House-Surgeons, Dressers, and Clinical Clerks, as the most effectual way of obtaining that kind of knowledge, the importance of which we are endeavouring to impress. In many of the Hospitals these posts are thrown open to the Students—a most praiseworthy arrangement; and we recommend those Students to whom money is a consideration, to select such Hospitals as their places of study.

Nothing gives practical experience so effectually as a sense of responsibility. Under such a feeling, all the energies of the mind are quickened and brought into play; caution is

induced, and a mistake once made and pointed out is not likely to be repeated. Sound rules of acting are impressed upon the mind; and one of the greatest of all virtues, self-reliance, is gradually acquired. We now wish our young friends God speed! and trust that their time will be pleasingly and profitably used.

SUMMARY OF THE WEEK.

THE INTRODUCTORY LECTURES.

These annual commemorations of Introductory Lectures form a grand Medical *Symposium*. They prepare for the ardent, eager, impulsive curiosity of youth, a feast of Professional eloquence and of Medical erudition. This banquet to which at the start in study they are so liberally invited, is flattering as well as gratifying to them. It, moreover, gives opportunity to the unfledged Professor to make the first flight with virgin pinion to determine if he has chosen rightly the sphere of his exertions;—if his "vaulting ambition" has compassed the right circle in which to feather his flight, or if he overleaps himself to "fall on the other." We are fully convinced of the high interest each Professor takes in the welfare of the classes committed to his charge: nevertheless, the importance of the occasion is liable to be damaged by hacknied iteration and reiteration of the same theme. The modest revelations of science and pathology require no such resonant echoes. The high interests involved render the occasion too important to be tritely treated, or ostentatiously displayed. They should come fresh as youth upon the sense, and free to the feelings. Aspiring and ambitious youth should be introduced into the career and walks of life by every inducement, and greeted at its threshold with every encouragement—to have pointed out to him the prizes to be obtained, and the labour to be incurred. It is well to beckon him on to the manly contest, and cheer him to the first conflict of life. Having once trailed the slot, young blood will warm in the chase; the excitement of the numerous accidents inevitably met with by "field and by flood" will lead him on to the *death*. So will the young Student be beguiled by this manly and exciting strife. This high breath will require to be sustained by hope and by achievement. The steep, rocky precipices of life will need the refreshment of success to stem its crags and top its mountain-peaks: without, its heights would be never, and its levels scarcely ever, attained to repay the emprize. We do not depreciate occasions for rallying the well-strung sinews of the youthful Hercules, or for soliciting with persuasive encouragement the diffident and fearful aspirant, emulous, in modest guise, to solicit the favours of natural science—a courtship, if pleasant, not always prosperous; or by powerful appeals to awaken dormant and lagging energy: but we think the mode and the manner might be improved. The candidates in the various walks of our noble Profession converge to this city of the world from all points of the compass. To many the scene of this vast Babel, in which they have emerged for the first time, is sufficiently exciting, and is itself a wonder which fancy and reflection can hardly comprehend. London is no illusion, but a stereotyped reality, suggestive, nevertheless, of deep thought, and of painful and pleasurable ideas. A congregation of peoples so immense disperses all pedantry, annuls all trivial rivalries, in longings for the definite and for unity. We think the various Schools should unite and elect from amongst themselves *Public Orators* for the Session, limited to four or five in number. This might be easily accomplished, so as to secure the election of the coming men of science; of pathological distinction, and of acquirements, especially appointed to officiate at this Annual *Symposium*.

MEDICAL EVIDENCE.

How is it that no evidence given from a witness-box is so unreliable, unsatisfactory, and inconclusive as is Medical testimony? Moreover, none is received with so much suspicion, or so severely animadverted upon, as is Medical evidence. In a case of forensic inquiry—of poisoning, for instance—Medical analysts cabal together to get up opposing testimony. Mr Smith of this school, Mr Thompson of that, and Mr Brown of the other, are pitted as analytic gladiators;—the fight of test-tubes thus arranged to come off in the presence of the Lord Chief Justice; the arena, the Queen's Bench. On another occasion, the question to be inquired into may be, whether a man can survive several days who has received mortal injury; say, traumatic rupture of the liver in two or three places, with fracture of "the arch of the thorax, and several ribs on each side also fractured?" Another eminent physician, considered by idol-worshippers the physiologist *par excellence* of the day, gives evidence in a trial of life and death. This gentleman pays a visit in consultation to a patient suspected of being poisoned by her husband. The visit is of *four minutes'* duration, ostensibly made to establish and support other evidence of witnesses upon the suspicion of a poisoning by antimony being perpetrated by the husband. The evidence of poisoning in this case was limited to and guided by the existence of symptoms which are common to idiopathic gastritis, enteritis, and the administration of mineral poisons. It was *the expression of the countenance of the patient*, which the first penetrating glance of the eminent physician detected on entering the room of the patient, and four minutes determined his conclusions. His testimony, as he knew full well it would, formed an important element in this juridical decision. That antimony had been given, and that the patient was poisoned, were the questions at issue. Most probably a large *honorarium* passed for this visit of four minutes. A longer tax of time in the witness-box might be well and gracefully spared, in consideration of a still larger *honorarium*, in elucidation of this erudite Medical *conspectus*. In this case there was no evidence upon which to rely, or to build a superstructure that would explain the forfeit of life. A chain of circumstances implying strong suspicion no doubt existed, but that was all.

The tendency of Dr Tyerman's evidence, in the Colney Hatch case, to infer in the case of William Swift a state of insensibility peculiar to insane people, was not relevant. The apparent insensibility or stolidity of insane patients to sensations of cold, or heat, or pain, is perhaps not difficult to explain. These are instances of common sensation. But voluntary or involuntary muscular action, as also the performance of organic functions, are incompatible with certain conditions of injury, traumatic lesion, or fractured bones. Pain and irritation, although perhaps less manifest in the lunatic, are also inseparable. Dr Tyerman, in his evidence, says,

"There was a post-mortem examination on the following Monday morning, and it turned out that the arch of the entire chest was fractured, and several ribs on each side were also fractured. There were also two slight ruptures of the liver, and there were two or three pints of extravasated blood in the stomach. (The witness then read the notes made by him upon the post-mortem examination, describing the appearances presented by the deceased.) At this time there was no suspicion that the prisoner had used any violence towards him.

"Cross-examined: The deceased was paralysed when he was admitted to the Asylum, and his condition in this respect would render him less sensible to pain, and in some cases, he believed, it would occasion complete insensibility to pain. Patients afflicted with this form of insanity would sometimes attempt to walk about with broken limbs. He had seen several instances of this kind during his experience at Colney Hatch. In one case, a patient who had fractured his knee-cap walked about, without any apparent pain, very shortly afterwards. In another instance, after a patient died, it was found that several of his ribs were fractured, and on the morning of the day of his death he said that he was quite well."

We conclude the insensibility implied by Dr Tyerman, in his evidence, is *anæsthesia* from paralysis. The functions of locomotion and of respiration in the case of the man Swift were not invalidated or impaired. The conclusion inferred by Messrs Partridge, Luke, and Barnard Holt is the only physiological solution of the mystery; namely, that the injuries occurred (*which caused death*) within a very recent period. Or, if a greater latitude of time be admitted, it might as well be inferred that this condition of insensibility would allow a patient with broken legs to *walk*, not merely *attempt* to walk (for the parallel is not forced between such a case and a man with lesion of the respiratory muscles, in whom "the arch of the entire chest was fractured, and several ribs on each side were also fractured," being able to perform the function of respiration). This induces the inference that the substitution of padded rooms and individual

control for personal and physical restraint introduces a new element. Insane fury is not, under the latter circumstances, to be always controlled by human forbearance and personal subjection, in which, unavoidably, the passions and feelings of the attendants, at the best but human beings, are sorely tried by immediate conflict and violent struggles. There is no other appeal. To moralise, or to reason, is negatived; a foregone conclusion has decided against such resources as useless, if not trifling. Thus, human passions are brought into open conflict with the insane paroxysms of the patient, and living muscular force must be resorted to, under the most exceptionable circumstances. It is much to be regretted that these means are practised where no human eye penetrates; the actors in the struggle and unfortunate patients being the only witnesses; the superintendent is thus placed in a position which demands almost angelic qualities to entitle him to the exercise of such responsibility.

THE SPIRIT OF THE PERIODICALS.

(Continued from page 225.)

"But there exist other poisons which equally destroy the vital properties of the locomotive apparatus, although a totally different histological element becomes the seat of disorganisation. We allude to the toxic agents, which abolish contractility in the muscular tissue; you will find them infinitely more numerous than those which confine their action to the nerves. Among this class of bodies, digitalis and upas antiar have already been mentioned; and the attention of American physiologists has lately been drawn by Dr Mitchell, of Philadelphia, to the properties of two other substances, which are known by the Indian names of Corrowal and Wao. Their action a similar to that of upas, although of greater intensity. The active principle of the veratrum album, or veratrine, a substance now frequently employed in practice, also exerts its influence upon the muscular fibre, to the exclusion of all other tissues; and a large number of poisons, with the chemical composition of which we are imperfectly acquainted, evidently belong to the same class.

"The small arrows now placed before you were forwarded to us by M. Boussingault. These weapons are extensively used in South America. The nature of the substance with which they are impregnated is still a mystery to us; they were supposed to have been charged with woorara, but their action is of a totally different kind: the muscular, not the nervous, fibres are affected by the wounds which they inflict. Although unable to state in a positive manner what this poison really is, I am tempted to believe that the venom of toads is the substance employed. The Indians of New Granada are known to make use of a small variety of this animal, which is found in great abundance in that country, for the purpose of poisoning their weapons. After collecting a large number of toads, they impale them upon wooden spits, and roast them alive. The heat causes the animal to eject its venom, into which the arrows are dipped. This latter substance is known, in fact, to exert a most powerful action on the muscular tissue. But the unknown principle with which these arrows are impregnated differs so completely in its properties from those usually attributed to animal poisons, that we shall seize the present opportunity to enter into some considerations on the subject of venoms in general, and that of the toad in particular, our conclusions being the result of the researches we have lately undertaken on this interesting and hitherto obscure part of toxicology.

"The effects produced on animals by these poisoned arrows would appear at first sight to be strictly similar to those produced in our own climate by the venom of toads; but when we inquire into the chemical composition of this new substance, we find it to be a perfectly stable compound, the properties of which are not destroyed by plunging it into boiling water or dissolving it in alcohol. The arrows which have been allowed to rest for a certain space of time in this latter solvent are found to have lost their destructive power, although no change has taken place in their dark brown colour; and the liquid in which they have been kept being gradually evaporated, the solid residue left behind appears to contain the active principle which imbibes them, for on redissolving it in water a poison is obtained which produces on animals the same effects as the arrows themselves.

"But the opinions usually entertained with respect to venoms are entirely opposed to such a result. Animal poisons are in general considered as resembling ferments in their chemical properties, being easily destroyed by the action of heat, and modified by dissolution in alcohol and other powerful solvents. We ought, therefore, in concordance with generally-received opinions, to have surrendered our former hypothesis; but, however satisfactory the inductions drawn from previously-ascertained facts may appear, an experimental verification is always indispensable in sound physiology, even in those cases in which it seems useless, and almost absurd, to require experimental proofs. Acting in conformity with this rule, which has always directed us up to the present time in our labours, we have examined in its turn the venom of toads, for the purpose of ascertaining whether its characteristics were really such as had been supposed; and, contrary to our expectations, we have found it to be soluble in alcohol, and in all other respects as stable a compound as the active principle of these American arrows, for the action of boiling water destroys none of its properties.

"It had been supposed, however, that no venom was fatal to the animal itself which secreted it; and as the poisonous arrows produce marked effects upon the toad, we found it necessary to try upon this animal the results produced by the inoculation of its own venom, in order to ascertain whether the opinion generally entertained on this point was scientifically true. The experiments undertaken for this purpose do not allow the slightest doubt to remain on this point. The toad is killed, like other animals, by the inoculation of its own venom; it is, however, true that the action of this poison is infinitely less intense in toads than in frogs, of all other animals those which resemble them the most in organisation; and it might hence be inferred that a certain degree of truth exists in the above-mentioned opinions. Let us bear in mind, however, that the resistance of the toad to all kinds of poison is infinitely superior to that of the frog; that strychnia, upas, and various other substances, act in much smaller doses upon the latter than upon the former animal; a fact which agrees with the lower excitability of the nervous system in toads.

"All these phenomena may, therefore, be reduced to a general principle, which we have strenuously endeavoured to inculcate in the course of the present lectures; namely, that no essential differences exist between the homologous tissues of different animals; that properties observed in one case are found to exist throughout the entire scale of being, although considerable variations in their intensity are met with, even in the case of neighbouring species. You also perceive that our knowledge of venoms is less advanced than the other branches of toxicology, and that it is urgent to repeat a new series of experiments on each of those substances in particular; for we are not prepared, up to the present moment, to attribute the properties enjoyed by the venom of toads to the whole series of animal poisons; farther researches are indispensable to settle the question.

"Let us now, gentlemen, after this digression resume the explanation of the effects produced by muscular poisons. The principal result of their action is sudden arrest of the heart's motion; and in this respect they might also be divided into two classes. Some of them act upon the heart before affecting the voluntary muscles: such is the case with digitalis and upas antiar. Corrowal and wao enjoy this power in a still greater degree. The reverse is the case with other poisons; they act upon the voluntary muscles at first, and do not paralyse the heart till a later period of the destructive process; the American arrows belong to this latter class. It is, therefore, easy to conceive how wide is the difference between the intensity with which these poisons act in animals differently organised. A very small dose of corrowal produces instant death in birds: a mammal survives a few minutes; while frogs resist the action of this substance for a considerable space of time, these animals, as you are aware, being able to survive a few hours after the total ablation of the heart.

"We shall now perform a few experiments on various animals with these different poisons; and you will find that, far from resembling woorara and strychnia, which destroy life without leaving the slightest vestige of their action, these muscular poisons actually produce deep physical changes in the tissue, which loses its physiological properties under their influence.

"(At this stage of the lecture a couple of pigeons are brought forward; an incision is made into the breast of both, laying bare the muscular fibres, and on applying test-paper, a decided alkaline reaction is met with in both cases. One of the pigeons is then killed with a poisoned arrow; the others with a solution of woorara injected into the cellular tissue. A frog is at the same time poisoned by introducing a small dose of corrowal under the skin; it is then replaced in the jar from which it had been taken.)

"You perceive, gentlemen, that the muscular tissue offers a decided alkaline reaction in the healthy state. But in animals poisoned with any of those substances which act upon the contractile elements, the reaction of this tissue becomes acid, and the *rigor mortis* occurs immediately after death; two changes which spontaneously take place in dead animals, but only after a space of twenty-four hours has elapsed. The electrical properties of this tissue equally undergo a singular alteration, for, in the ordinary state of things, the external surface of a muscle is positively, and its internal or cut surface negatively, electrified; the reverse is the case in animals poisoned with these toxic agents. And, lastly, on opening the bodies immediately after death, the heart is found contracted, motionless, rigid, and totally empty; so that its transparent walls, in the frog, have lost the ruddy colour imparted by the presence of blood within the cardiac cavities, and appear perfectly white and colourless.

"In all such cases the muscular element alone has been acted upon; for if, on poisoning an animal with one of these agents, you were to apply a ligature round one of the limbs, and thus prevent the poison from reaching it, you would find that while the other muscles of the body remained insensible to the action of galvanism, those of the limb thus preserved would readily obey its influence, when excited through the corresponding nerves: a proof that the muscular fibres alone have in this case been interfered with, the nerves retaining, as before, all their vital properties.

"(The bodies of the poisoned animals were now opened: in the pigeon killed with an arrow, the heart was found rigid and motionless, the muscles stiff and incapable of responding to the galvanic current. The same phenomena were observed in the frog, the heart of which was particularly rigid and perfectly colourless. On testing the muscles, their reaction was found decidedly acid. In the pigeon killed with woorara, the heart was found still in motion; and when at length its pulsations had ceased, galvanism was applied to it, and caused the parietes to contract; the muscles of the limbs responded readily and powerfully to the same agent, and their reaction was alkaline.)

"You will no doubt allow me, Gentlemen, to seize this opportunity of conveying to your knowledge our opinions on the subjects of the connections existing between physiological phenomena and the physical properties of the tissues which produce them. It may be correctly asserted, in a general manner, that the physiological properties of muscles, nerves, and all other tissues, co-exists with physical and chemical phenomena of a peculiar nature, and that a direct relation is to be found between the degree of intensity which each class of properties exhibits. Shortly after death the vital characteristics of the tissues disappear along with their physical and chemical properties: thus, in muscles, the electric current fails at the moment when contractility is

extinguished; and in the nerves the electro-tonic power disappears at the same moment as physiological excitability. But although we are tempted to view this connection between physical and physiological phenomena in the light of the necessary relations between cause and effect, I rather believe it to be a mere coincidence. It must not be supposed that the vital properties persist as long as the physical and chemical phenomena have not disappeared. A remarkable instance of this reciprocal independence is afforded by the following experiment:—A rabbit being killed by the section of the medulla oblongata, both nervous excitability, muscular irritability, and the electric muscular current disappear by degrees, and are totally extinct a few hours after death. But when the animal is poisoned with upas, a very different result is observed: the normal irritability of the muscles disappears twenty-five or thirty seconds after death, while the electric current persists during four or five hours. In the same manner, the alkaline reaction of muscles is not inseparably connected with their contractile power, nor the electro-tonic state in nerves with the property of transmitting the impulse of the will.

"Far be it from us to maintain that the disappearances of the vital properties of any given tissue is not in all cases the result of a material change; we only intend to show that in more cases than one that change is yet unknown and must be sought for in a different direction; the physical and chemical properties hitherto known to exist in our tissues are the inseparable attendants of the vital action, but do not appear entirely to create its powers.

"We shall here conclude, Gentlemen, our Course of Experimental Pathology for the present session: we shall resume these studies next year at the point where we now drop them; and, the general notions of the science having now been laid down, we shall devote our attention to a few particular points. We shall, therefore, endeavour to produce in sound animals some of the diseases with which clinical observation has rendered us familiar, by means of Surgical operations; and in observing their effects, in seeking to explain their cause, we shall never lose sight of our fundamental principle, 'That Physiology is the foundation-stone of Pathology.'"

Dr Goodfellow continues his Lectures on those diseases of the kidney known as *Bright's Disease*; and Mr Jones contributes an article on the *Treatment of Delirium Tremens by large Doses of Digitalis*, which we will quote in our next Number.

The 'Indian Lancet' contains the following article on *Femoral Aneurism and Ligature of the External Iliac*, by Dr Wylock:

"A somewhat obscure and not less curious case of aneurism of the femoral artery which fell to my lot may not be unworthy of record:—W. B., Royal Artillery, had been under my care on 25th February with bubo in both groins, and phagadenic ulceration of the penis. The ulcers on penis yielded kindly to treatment, and so also did the bubo or ulcer in left groin; that in the right, however, gave considerable trouble, and it was not until the end of April that it showed any signs of improvement. About this time it began to granulate and contract; but this action was accompanied with excruciative pain all down the front of thigh as far as the knee. On the 1st of May, the ulcer, which was before granulating and contracting kindly, became livid and tense, and granulations large and flabby; the pain increased in spite of all remedies. On the night of the 4th of May, I was called to see the patient, who was bleeding from the groin. I immediately went, and found that about 4 oz. of blood had escaped; but it was clotted, and apparently had ceased for some time before it was discovered. I could not find the place from which it had flowed. I applied cold and oil lint, waited about an hour and retired. About 4 p.m., next day, I was again called, and found the same state of affairs; made the same applications, and after a due time left.

"At about 4 p.m. on the 6th, I was again called by a man in breathless haste. I lost no time, and found the patient apparently lifeless in a pool of blood. I thrust my finger over the part, and dashed cold water over his face and chest. On his reviving, a jet of blood, 6 inches high, escaped. I had meanwhile, having determined on the necessity of an operation, sent for Mr Blechynden, the Commissariat officer. On his arrival, his finger was substituted for mine, and I proceeded to put a ligature on the external iliac artery. This I accomplished in from 7 to 10 minutes with perfect success. I had now leisure to examine the aneurism, which I found rough inside and capable of containing 3 or 4 oz. of blood; its centre was immediately under Poupart's ligament, above and below which it extended about 2 inches either way. The openings of the artery into and out of it were hard, and as distinctly defined as the openings into a stethoscope. The patient is doing well; but how long he will continue to do so, after his enormous loss of blood, remains to be seen."

Dr Purefoy contributes to the same journal an article on *Tubercular Meningitis*, attended with obscure symptoms, which we quote:

"The subject of the present remarks occurred in the case of a young man, a recruit in the Company's Service. Shortly after his arrival in this country, he was seized with a severe attack of bronchitis, which proved the means of developing the latent symptoms of a severe organic disease under which he laboured, and thus, indirectly, of throwing considerable light upon the nature of a secondary lesion of the brain, afterwards supervening, which otherwise must have remained in considerable obscurity as regards the accuracy of a diagnosis. Before presenting the reader with notes of the case, I should briefly say, although favouring the supposition that such a lesion was the result of tubercular deposition in the brain, yet I am not prepared to say so with certainty. One is naturally inclined to look upon cerebral symptoms grafted upon a scrofulous constitution as deriving their origin from such source. Yet were such the case in the present instance, the symptoms, as the case will show, are greatly at variance with what one is led to expect. The patient, a young man (ætat. 20 years), of thin and slender make, temperate habits, and in the previous enjoyment of good health, was admitted into hospital, Barrakpore, June 8th, suffering from a severe attack of bronchitis. He was not very many days in hospital before the paroxysms of dyspnœa, the copious muco-purulent expectoration tinged with blood, and constant cough, made me suspect the nature of his ailment. A stethoscopic examination of the chest, coupled with the physical signs, cleared up all doubts on the matter, and pointed out as the nature of his disease, tubercular infiltration with vomica in apex of both lungs. The usual treatment for such cases was adopted, but without much relief, and now for the first time his flesh and strength failed him, the appetite decreased, and there was almost total loss of sleep from the cough. In this state he continued without any notable change in his symptoms to June 15th, when, upon visiting him, I found him sitting upon a chair by his bedside, morose and taciturn, apparently indifferent to all going on around him. The countenance, pale and anxious, presented a wild and vacant stare; the eyes, dull but not suffused, were fixedly rivetted on one object, and when questioned it was with the utmost difficulty an answer could be elicited; when it was short, evasive, always tending towards some religious topic. There was no fever, no heat of skin present, nor throbbing of temples, nor abnormal condition of pupils visible. Pulse is 100, small and weak; bowels constipated. Ordered two aperient pills, and a blister to nape of neck. June 16th.—Still occupies the same position, and exhibits the same sullen disposition and aversion to speak. Hallucination confined to same subject (religion), upon which the mind is so rivetted he constantly bursts into tears. He refuses to be put to bed, to make use of anything. Bowels still confined. Ordered calomel, gr. x.; pulv. jalap. c., dr. j. June 17th.—Supported between two men, slept a little. General symptoms as yesterday. Bowels still refuse to act. Ol. Crotonis, gtt. ij., to be given immediately; a turpentine enema in two hours afterwards. June 18th.—Was induced to go to bed last night: got a little sleep; mental faculties improved. No cerebral symptoms discoverable. Bowels not operated upon. Ordered ext. elater., 2½ gr., to be made into two pills; one to be taken at once, the second if necessary in two hours. June 19th.—Bowels have been actively operated upon, evacuation consisting of scybalæ, since which nearly all head symptoms have undergone a marked change for the better. The patient is now quite rational.

"*Remarks.*—At first sight there may seem no difficulty in arriving at an accurate diagnosis regarding this secondary lesion. But supposing that bronchitic attack had not supervened, thus developing the latent symptoms of a diseased action, not only local, but constitutional; could one with any degree of certainty point out any of the above symptoms as originating in cerebral disturbance, the result of tubercular deposit? On the contrary, did we look to symptoms alone whereupon to base a diagnosis, would not the absence of all fever, of alteration in pupils, the age of the patient, presence of delirium, and the rapidity of the accession as well as the departure of all signs of mental aberration, point to some other cause as the probable source? Although hydrocephalus is essentially a disease of childhood, yet it is occasionally met with in more advanced life. When such is the case, must we expect to find the phenomena attendant upon the disease at the former period identical with those of the latter period of life? Is it not reasonable to expect, according as the reasoning faculties become developed, and the excitable condition of the nervous system diminished, we will find delirium substituted for convulsions, and many of those symptoms having a nervous origin wanting? If such a view of the case is admissible, might not the secondary lesion be accounted for by supposing the deposition of tuberculous matter to have proceeded so slowly as to give rise to no symptoms, until the balance of circulation in the part was altered by either the supervention of the bronchitis, or the obstinate constipation of the bowels?"

HOSPITAL REPORTS.

KING'S COLLEGE HOSPITAL.—Sept. 22nd.

Resection of Knee-joint.—Mr Hulke.

The patient, a woman about thirty years of age, received an injury of the knee some three years since, on a voyage to America, by falling through the hatchway. Inflammation and disease supervened, which after some time terminated in spontaneous cure, the joint becoming anchylosed. The patient went on well until about nine months since, at which time her knee received a wrench, or twist. Disease became renewed in the cartilages and ligaments of the anchylosed joint. Matter formed in the joint, which was discharged by the abscess being opened. Great constitutional and local irritation now occurred. She was suffering also at this time from uterine hæmorrhage. This aggravated the constitutional irritation, and seemed to augment also the local irritation, which likewise on its part apparently aggravated the uterine disease. Under these complications, health rapidly giving way, Mr Hulke decided upon removing the seat of disease by resection of the joint. The operation was performed by making the H section. On each side of the knee, a longitudinal section of about four inches was made through the integuments and tissues. A crucial section was then carried horizontally above the seat of the patella, cutting through tendons, ligaments, and cartilages into the knee-joint. This made a superior and inferior flap. The superior flap was then dissected upwards, discovering the extremity of femur, which was found necrosed and diseased. The extremity of femur being laid hold of with nippers and raised, was cut through with saw obliquely downwards and backwards. The lower flap was then dissected to show the heads of tibia and fibula, which were then cut with saw obliquely upward and backward. Thus, a sufficient angle was obtained, by removing the extremity of heads of bones, to admit upon apposition of a nearly straight limb from its previously bended position. To make this satisfactory, it was necessary to remove, by a supplemental cut, a small slice more from extremity of femur. No hæmorrhage took place, no vessels required tying. The flaps were brought together with ligature, and water-dressings applied; the limb being properly extended and secured in a M'Intyre splint, with anterior and posterior splints for thigh.

The *experimentum crucis* of this operation of resection is not arrived at maturity. Whether growth and normal development of limb be stopped by removal of the epiphigies of bones or not, is yet to be determined. If they be stopped by such removal, resection will not supersede amputation. It will in that case (unless modified removal of epiphigies may be practised, so that sufficient may be removed to effect the purpose of resection free from mischief), become a foregone conclusion that resection is not applicable to young, growing subjects. We hear of early cases of resection having resulted in dwindled leg, hanging useless from the thigh, in consequence of this operation. We confess to be sceptical upon this point, and hardly entertain the fear. Ossification radiates in the shaft and cylinders of long bones from the central diaphysis to the epiphigies.

GUY'S HOSPITAL.—Sept. 17th.

Lithotomy.—Mr Cooper Forster. Sept. 26th.

—Tumours of Neck.—Mr Cock.

A case of lithotomy, a child of three years old, was operated upon by Mr Cooper Forster. We have on more than one occasion had to revert to the frequent operations for lithotomy and amputation which have occurred at this hospital.

Tumour of Neck.

Mr Cock gave rather an interesting history of

the progress of this case. The patient was a man about thirty years of age. He first noticed the access of this tumour nine years since. Mr Cock believed its existence dated from an earlier period. It had gradually enlarged and extended until now. He explained that it was one of those deep-seated tumours extending under the muscles which almost always proved of malignant character. This had become very large, extending anteriorly, so as to be buried under the sterno-mastoid muscle of the left side, taking its course under the muscles on the side of the neck posteriorly, as far as the vertebræ. Mr Cock believed it had travelled as far as the transverse process, and had formed a connection with the ligament of the fifth vertebra. It would consequently be impossible to remove such a tumour wholly. From its painful character, as well as from its great size, this tumour had lately caused considerable irritation and inconvenience, and the patient urgently sought relief. Under these circumstances, notwithstanding the tumour was so dangerously situated, imbedded amongst large arteries, Mr Cock thought it was justifiable and proper to endeavour to afford relief by an operation. Until this occurred, it was impossible to say what the tumour was—whether deep-seated, fibrous, fatty, or malignant. If the first, he proposed to follow it through the anatomical region it occupied with finger and scalpel-blade, and handle as well as he could. If it should prove malignant, it would become necessary to stop the operation and close the wound. The tumour showed purple discolouration over its most elevated portion, which elevation seemed circumscribed to 2½ inches in diameter under the mastoidean region. Under chloroform, Mr Cock made an incision at its base anteriorly, and proceeded by dissection to trace its connections. On reaching and examining the tumour, he found it to be malignant. This circumstance decided the staying of further proceedings. If this state of things had not been discovered, the further progress of the operation would have been attended with considerable difficulty from hæmorrhage, several arteries having already been secured. Mr Cock made a few remarks, to the effect that it was justifiable to afford relief by amputation in such cases when practicable. In this instance it became necessary to leave the unfortunate man to his fate.

UNIVERSITY COLLEGE HOSPITAL.

September 19th.—Fistula in Ano. Sept. 27th.—Bloody Tumours of Lip Removed—Tumours of Breast Removed.—Mr Thompson.

This operation for fistula in ano was performed in the usual way by Mr Thompson.

Bloody Tumours of Lip and Gum (so-called Epulis.)

This patient, who was a young man about twenty-eight years of age, had been inconvenienced for some time by this tumour. He had had ligatures applied on three several occasions, but the bleeding tumours returned. Mr Thompson stated that it was the character of these tumours, that they were more troublesome than dangerous. They very seldom proved malignant, although that did occur sometimes. They sent roots into the bone of the alveolary process, of which it consequently became necessary to saw away a portion. Mr Thompson proceeded to remove the two front teeth of the upper jaw to effect this purpose. After dissecting back the frænum of the lip and soft parts of the gum, he applied the saw and removed away a portion of the alveolary process of the superior maxillary bone. It was the nature of this fibrous tumour to shoot its roots into the bone, and the only successful method of cure was to follow them by extirpation of a portion of the bone.

Tumour of Breast.

Mr Thompson reverted to the number of cases of tumours of the breast operated upon recently at University College Hospital. The case we reported about a fortnight since, which Mr Thompson removed, was progressing favourably. It was a large tumour of a doubtful character. Although the wound and parts had been attacked with erysipelas, which had been prevalent in the hospital, the wound was now healing. The present case, a woman twenty-five years of age, had been noticed about six months. The tumour, situated on the right breast, superior and internal to the nipple, was small, moveable, and presented no untoward appearances—a slight blush or discolouration existed over it. Under chloroform it was removed by oval section, and proved to be a large sebaceous gland, situated in a tough, thickened cyst. If its radius had been known, it might have been cut down upon and pushed out. Most of the other cases which have occurred at this hospital have been more advanced in years, their ages running from forty-five to fifty-five.

Varicose Vein.

This case is noticeable, inasmuch as although only one vein was diseased, it was attended with great and constant pain. The vein was pierced on the anterior aspect of the leg at two points, with silk passed in the usual way over and under them, and tied over a quill-like piece of wood.

GREAT NORTHERN HOSPITAL

This aspiring young hospital, situated far away, demands and truly deserves regard and notice. Notwithstanding its distance, its polar tendency excites a normal attraction. We consequently were drawn into these northern parts, not without edification and improvement resulting from our visit.

The exterior of the Great Northern is of so unpretending and modest a character, that although its "name" had sounded well and frequently upon our ear, we are almost ashamed to say that at our first visit we could not find its "local habitation." Surely this will not be an abiding shame! If so, it will not rest with us, but with an undiscerning public. At a time when the large hospitals seem to be holiday-making, we found ourselves in presence of ardent appetites for the occasion, earnestly in search of surgical refection, with a numerous and goodly company of select and enterprising Surgeons. This bevy seemed on excellent terms, keen to inquire, and eager for the business before them. Amongst the *entremets* and smaller *trifles*, the standing *billet* runs thus:—

Resection of Hip-joint.—Mr Price. Amputation of Lower Maxillary Bone.—Mr Adams. Removal of Tumours from Neck.—Mr Savory.

Partial Excision of the Hip-joint.

Mr Price is well known to the Profession as an advocate for surgical interference in certain cases of diseased hip-joint. In the columns of this Journal have been lately published the views of this surgeon regarding excision of the hip-joint—partial and complete—in instances in which the articulation has been more or less destroyed by that form of disease termed morbus coxæ. In a paper read before the Medical Society of London during its past session, Mr Price reviewed all the cases of excision of the hip-joint which had come, more or less, under his observation, and the conclusion he drew was in every way favourable to the adoption of operative measures in such cases in which the joint was greatly implicated, and both femoral and pelvic portions included. The operation which we saw performed at the Great Northern Hospital fully showed the correctness of diagnosis, and the great advantage of direct surgical interfereuce. A little boy, about seven years of age, had suffered for nearly four years from a diseased condition of the hip articulation of the left side. He had been under notice at various institutions, but no permanent benefit had resulted from the treatment adopted. He had been under the observation of Mr Price for some months, and considerable relief had been obtained by the application of a long side-splint, which had retained in position and absolute rest the parts forming the articulation. When the little patient was brought into the operating theatre, we noticed that the left leg and thigh were much shorter than their fellows, and greatly diminished in size, as much as two or three inches. Great pain was experienced on pressure being made over the great trochanter. The buttock was globular, and much larger than the right. The thigh was semi-flexed on to the belly. A sinus opened on to the front of the thigh. Mr Price remarked that although under chloroform considerable movement of the joint was permitted, and no grating sensation produced by manipulating with the limb, yet he did not consider these circumstances evidences of non-existence of extensive disease. The suffering had been severe, and the constitutional symptoms likewise formidable and indicative of much mischief. But, in such examples, experience and former operations had taught him that constitutional symptoms were more often to be relied on as pointing to considerable disease than any local expressions of morbid action. Hand in hand, however, the continued evidences were, in his mind, amply sufficient ground for interference in this particular instance. An incision, two to three inches in length, was made over the inner side of the great trochanter, and the capsular ligament (which was to all intents entire so far as retention of the end of the femur was concerned) readily opened. The head of the femur was found almost entirely removed, and a large necrosis, occupying the middle portion of the acetabulum, was easily detected and removed. The lips of the small wound were adjusted with sutures, and the limb bandaged to a long interrupted side-splint. This is one of the most interesting cases of the kind we have witnessed, and we shall recur to it again in a short time, when resolution shall have afforded the little patient a useful limb.

Excision of Lower Maxillary Bone.

This patient, a man forty-eight years of age, noticed enlargement of the lower jaw about four months since. It came under the care of Mr Adams some time afterwards. He observed an internal and external abscess, which induced him to form a rather favourable prognosis. The disease rapidly increasing, he decided to make an exploratory operation, to solve the doubt existing of the nature of the disease, and proceed further if required. A horizontal section was carried along the body of the lower maxillary bone, which quickly discovered its nature. Recurrent fibrous tissue or malignant epithelial cancer was found to exist, having penetrated deeply and extensively into the bone and soft parts. The body of the bone was quite gone in its centre; and the disease extended, including the angle and ramus of the jaw, to within half an inch of the symphysis. It required to be eradicated with saw and nippers, and followed with knife in every direction. It had burrowed under the base and root of the tongue. In dissecting it away, the lymphatic salivary gland was exposed. It was necessarily a tedious and exigent operation, and numerous vessels had to be secured. The wound was brought together in the usual way with ligatures and strapping, and cold water-dressings applied.

Tumour of the Neck.

This being a simple fatty tumour, Mr Savory removed it from its cyst, by a simple oblique incision dissecting out the fatty development.

GENERAL CORRESPONDENCE.

DIPHTHERIA.

To the Editor of the Medical Circular.

Sir,—I beg to forward to you the following remarks on the disease termed "Diphtheria," and also regarding a case of that disease which, along with others, occurred to me in the course of practice.

Before doing so, I would premise that in London, in a population of about three millions, the weekly number of cases of genuine Diphtheria averages no more than seven or nine, and that the average results of treatment are about one recovery to seven deaths. Were we, however, to judge from the statistics sent from some parts of the country, Diphtheria would appear to be there not only more prevalent, but also far less fatal: but a careful investigation would undoubtedly show that neither the one nor the other is the fact, and that many of those country cases (especially those in which recovery has taken place) have in reality been severe forms of quinsey, and perhaps in some cases merely aggravated forms of *Cynanche tonsillaris*.

The case of Diphtheria to which I refer occurred in February, 1860, in a girl of seven years of age, and proved fatal in five days. The disease, attributable to exposure to cold and wet, was first ushered in with the usual symptoms indicating inflammation of the throat, such as dyspnœa, pain of affected parts aggravated by pressure and by attempts to swallow, and attended with constitutional disturbance. It would be too tedious to detail all the successive symptoms; let it suffice to describe only those peculiar and specific symptoms which characterise that disease termed "Diphtheria;" viz., the great depression of the vital powers; the low type of the fever, owing to the virulence of the morbific poison affecting the circulating and the nervous systems; the pallid face; the thready pulse; the absence of the tumefaction, and of ulceration of the velum pendulum palati and of the pharynx, but the presence of an intense dark redness of the surface, dotted at first here and there only with small circumscribed patches of a greyish, tough, persistent, viscid, and plastic exudation. As the disease proceeded, this exudation, in spite of all means, gradually covered the whole surface, and invaded the larynx and the trachea. Before the fatal termination, there were added to the dyspnœa and the difficulty of swallowing, loss of voice, and apparently a paralytic condition of the muscles of deglutition and of respiration, resulting, doubtless, from the disturbed state of the nervous system. A variety of remedial measures were had recourse to, such as laxatives, calomel, opium, quinine, camphor, sesqui-carbonate of ammonia, æther, brandy, wine, beef-tea, &c.; touching the parts with a strong solution of

nitrate of silver; friction of throat with powerful liniments, containing camphor, a little tinct. opii, and liquor ammoniæ, so as to produce vesication; counter-irritation also to neck and upper part of chest, application of constant warmth to the lower extremities, and various other appliances.

In conclusion, I beg to state that though the above means proved of no avail in this case, yet their adoption in another case, which occurred abont the same time, was successful.

J. B. Nicolson, M.D., M.R.C.S., L.S.A.

OUR NOTE BOOK.

GUNSHOT WOUND OF THE COLON.

During the recent campaign in India, in an action with the rebels in the Jugdespore jungles on May 12, 1858, Private Michael McCurteney, of the 10th Foot, received a gunshot wound of the abdomen. A musket-ball entered his left side between the tenth and eleventh ribs, in a line from the anterior superior spine of the ilium, passed downwards and backwards, and escaped one inch and a half to the left of the spines of the first and second lumbar vertebræ, close to the crest of the ilium. When hit, he was observed to whirl round and fall heavily to the ground. He suffered much from shock, and had brandy and ammonia administered at intervals during the next twelve hours. There was only slight bleeding from the wound, and no blood was observed to have passed from retum or bladder. Soon after this peritonitis set in, accompanied with vomiting, for which calomel with full doses of opium and effervescing draughts were administered, with alleviation of the symptoms.

On the evening of the 14th, his orderly came to report that his bowels were, as he termed it, "all gone." On examination, it was found that about two ounces of fæces had escaped from the posterior opening, thus indicating perforation of the descending colon. His condition at this time was briefly as follows:—Skin cool; pulse 94, small; tongue somewhat dry, complaining of thirst; expression anxious, with occasional sickness and vomiting. Abdomen tender and tympanitic in its lower half; had slept occasionally for short periods, but this was evidently produced by the opium. The day previous he had been carried about five miles in a dooly, and on the 15th he was again removed sixteen miles back to camp. Here he remained three days under treatment in the regimental hospital, the treatment being still directed to subduing the peritonitis and allaying the vomiting, and with a good measure of success. The utmost attention was paid to cleaning the opening in his back, and a large loose compress of tow applied to receive the fæcal matter as it escaped. He was now removed some eighteen miles to a Depôt Hospital which had been established for the sick and wounded of the force. While there, his treatment, if we except the dressing of the wound, was purely medical. Its results were most satisfactory.

On June 19 the regiment was ordered into quarters at Dinapore, and he being brought with it, came again observation. He, though much emaciated, had a healthy look, and was in good spirits. Abdomen felt natural, and, except in one or two spots, pressure gave him no pain. The wound in his side had nearly healed, that in his back had contracted considerably, although fæces in large quantity were still passed from it, but at the same time his bowels were occasionally moved pretty freely in the natural way. There was little remarkable in his case from this time up to the middle of July, when, dysentery being prevalent, he was seized with that disease. Stools containing blood and mucus only were passed by both the natural and artificial anus. The constant trickling from the latter was a source of great discomfort. He was treated for this, as if no wound of the colon had been present, by the usual remedies for dysentery, and, almost contrary to expectation, recovered,—and so much so, as to be able in August to proceed with other invalids to England. By this time the opening in his back had become so diminished, that for two days at a time—although his bowels were well moved *per anum*—scarce a trace of fæcal matter would escape by it; and hopes were entertained that, by supporting the part with well-fitting compresses, and using stimulating astringent applications to the wound, it might be completely occluded. But for sudden perturbations of the bowels, induced by climatic causes, this, no doubt, would have been accomplished at the time.

Although he promised to let me know the subsequent progress of his case, he neglected to do so, and I lost sight of him until a few days ago, when a corporal of the regiment, who had recently returned from furlough, told me that he had met him in Belfast in March last, and that he desired him to inform me of his complete recovery; that although there was still a very small hole in his back, nothing but a slight watery discharge came from it, and that his bowels were all right, and opened regularly in the natural way. He was then performing the duties of monitor in a poor-house in that town.—Dr Tullock, 10th Reg., in 'Medical Times.'

WARTY TUMOUR ON THE NOSE OF A BOY.

Geo. C——, aged 12, admitted June 13th, under Mr Prescott Hewett, into St George's Hospital. Six months previously he had noticed a small wart on the tip of his nose, about the size of a pea; it grew very fast, and in about a month it had more than doubled in size, and looked black. Some acetic acid was applied by his schoolmaster; this did not do any good. Two months ago the tumour was nearly an inch long, and half an inch wide. He was then seen by a surgeon, who applied chloride of zinc. This reduced it in size. It very shortly afterwards began to grow forwards with great rapidity. On admission there was a warty growth, of cone-like form, situated on the tip of the nose; it was nearly an inch in height, three-quarters of an inch in length, and half an inch in breadth; it was very painful, and bled if pulled about; it looked very like epithelioma. There was also a small wart situated on the upper lip, just above the angle of the mouth; health was very good. The boy's face is of a peculiar colour from having been exposed in an open boat in consequence of shipwreck; the skin is red, and covered with black blotches; some like large freckles, others like deposits of black pigment. The treatment consisted in the application of nitric acid on five different occasions, and a perfect cure was accomplished.—'Lancet.'

ON THE EXCLUSION OF LIGHT IN THE TREATMENT OF ACUTE EXANTHEMATA.

While treating of acute exanthemata in relation to the nature of the epidemics which may prevail, Dr Pockels attaches great importance to the due regulation of light. Experience teaches us that in darkness plants become pale and weak, but under the influence of a brighter light the irritability of the nervous system is augmented, and the metamorphoses both in the vegetable and animal economy are accomplished with more rapidity, while during sleep they are diminished. In a sick-room we avoid bright, glaring colours, and take care that reflecting objects shall not remain within the field of vision, especially when the excessive irritability of the nervous system prevents sleep. These facts induced the Author to try the effect of darkening the room during the treatment of the acute exanthemata, and that the more because he had already remarked their favourable course in those cases in which necessity compelled the patients to remain in dark places. He completely darkens the room, not only during the period of the symptom, but until that of desquamation has been passed through. Of course, in slight forms of disease and mild epidemics this care is superfluous; and in an aged, cachectic, or asthenic condition of the patient, the room is only so far darkened as to render the symptoms milder. The first influence of this darkening is seen in its effect on the exanthem, the development of which it arrests, all the local symptoms being moderated in severity. It, moreover, moderates the ensuing reaction, the febrile action being rendered much milder, the exhaustion of the patient prevented, and his convalescence favoured. The convalescence is further remarkable in not being attended with the same amount of secondary affections. In many cases of scarlatina no other treatment is required, and in varioloid affections disfiguration by scarring is much diminished.—'Varge's Zeitschrift,' band xiv, p. 1, and 'Medical Times and Gazette.'

COMPRESSION IN THE TREATMENT OF VARIX.

Professor Botto, of Genoa, has of late treated varix with success by applying compression at two points along the course of the saphena vein; a procedure, he thinks, very preferable to puncturing or injecting the vein. At first he employed digital compression, but afterwards he substituted his present plan of making it. The patient first assumes the standing position for a long period, in order to induce as much distension of the varices as possible. Two pellets of charpie are then fixed firmly by means of two circular rollers over the saphena interna vein, the one above and the other opposite the knee, in such a way as to comprise between them an interval of about sixteen centimetres. Some inflammatory action is at first produced; but this soon subsides, and in the course of a month the vein becomes obliterated, and reduced to the state of a hard, compact cord. The large varices between the knee and groin will have entirely disappeared; but to obtain a complete cure of those of the leg and back of the foot, a new compression will have to be instituted at the lower third of the leg.—'Rev. Méd.' 1860, vol. i., p. 369, and 'Medical Times and Gazette.'

ACUPRESSURE.

At the Academy of Medicine on Tuesday last, one of the members, M. Bonnafont, just arrived from Edinburgh, and glowing with grateful enthusiasm on the strength of Scotch hospitality, thought it incumbent upon him to deliver a short address, most complimentary to the practice of Edinburgh generally, and Dr Simpson in particular. M. Bonnafont described to the Academy the method for arresting hæmorrhage after amputation devised by the talented Scotch Professor, and urged upon the Parisian hospital surgeons the adoption of acupressure in their practice. He also showed one of Dr Simpson's uterine supporters, of the good results of which he himself had been an eye-witness. M. Velpeau, in reply to these observations, stated that he himself believed, from his own experiments, that acupressure, such as that described by M. Bonnafont, and practised in Edinburgh, was an uncertain means of arresting hæmorrhage, and would never supersede the ligature, although he readily admitted the imperfection of the latter means, and thought it most advisable, when possible, to avoid the presence of a foreign body in the wound. M. Velpeau had lost sight of acupressure for the last year and a half, when M. Fouchet undertook to investigate by experiment the amount of benefit to be obtained from this plan, in comparison with the ordinary method. M. Fouchet, who was most enthusiastic and confident at the time, had not published his observations on the subject; and M. Velpeau thought that his silence boded no good in favour of acupressure. He had himself, in 1830, adopted a modification of the same process, and had at the time a difference concerning its right of priority with M. Amussat, by whom M. Velpeau's claim was contested. He had, however, returned to the ligature, and was disposed to stick to it until he saw some better method proposed; and such a method the acupressure, as described, certainly was not. M. Depaul, in his turn, criticised the uterine supporter shown by M. Bonnafont. He did not believe that it was safe; it often set up inflammation of a dangerous character, and on its removal the womb invariably reassumed its unnatural position, unless—and these were the cases called cures—the organ had, by the inflammation produced, been glued to the surrounding textures, and so rendered immovable. —'Lancet.'

PERCHLORIDE OF IRON IN DISEASES OF THE SKIN.

As the result of numerous trials, M. Devergie arrives at the following conclusions:—1. It is the most efficacious agent which has been employed in the internal treatment of purpura simplex and hæmorrhagica. 2. It may be employed with much advantage internally in the cachetic and anæmic condition which so often accompanies certain forms of disease of the skin, as rupia, ecthyma cachecticum, impetigo scabida, and atonic ulcers of the lower extremities. 3. It is not of the same value in active hæmorrhages or in the acute forms of the diseases just named. 4. Employed externally, in the liquid form, in different degrees of strength, it may exert great influence in modifying the condition of wounds; atonic, scrofulous, and syphilitic ulcers, and various forms of syphilitic diseases of the skin, accompanied by secretion. Under its employment, obstinate morbid conditions have yielded which have resisted a great number of

external agents. Its use, in the form of ointment, is most advantageous in the declining period of diseases with secretion; but used in pretty strong doses, it is also useful in certain squamous affections, diminishing the period of time necessary for the application of such disagreeable substances as tar or cade oil.—'Bulletin de Thérapeutique,' tome lviii., p. 297.

ON SEA-SICKNESS.

Dr Armand, after describing the phenomena of this most unpleasant condition, proceeds to give his views of its causation. After rejecting various hypotheses as untenable, he continues: When any one waltzes for the first time, it seldom happens that the apparent turning round of surrounding objects does not produce such a degree of vertigo as to cause him to stumble, or even to fall down, while there is a tendency to nausea; in fact, a condition is produced for a short time exactly identical to what is met with, but for a longer time, on board ship in a rough sea. A similar condition is occasioned if we mount and go round upon the wooden horses we meet with at fairs; if, while fording a rapid stream, we allow ourselves to be fascinated by the rapidity of the current; in some people it is produced if they look out of a carriage at the sides of the road, and watch the trees apparently in rapid motion. All these circumstances, including sailing, have this in common, that they give rise to an interference with the laws of perspective, produce perversion of vision, cerebral fatigue, and a whole series of sympathetic phenomena, reacting from the brain upon the stomach and the entire organism. A proof that the fatigue of the eye is in these cases the chief cause of the peculiar feeling is, that, after having waltzed, the most certain means of getting rid of the vertigo is to shut the eyes for an instant; while, on board ship, a pretty sure means of avoiding sea-sickness is to look steadily upon one point—a better still is to lie down and close the eyes. Sea-sickness should not be looked upon as a disease properly so called, but simply as a temporary indisposition, disappearing as one gets accustomed to navigation, except in exceptional cases, where, from a continuance of rough weather, and as the consequence of a peculiar idiosyncrasy, the continuance of this state may give rise to accidents of a certain gravity, such as the vomiting of blood. The obstinacy and the energy of vomiting may have a still worse effect in persons suffering from various kinds of prolapsus, or in producing it in those who are predisposed. Pregnancy is an unfavourable condition, as the movements of the vessel and the repeated vomiting not unfrequently bring on premature labour. The best means, if not of preventing, at least of moderating the violence of sea-sickness, is to wear a belt round the body, to assume the horizontal position, and to close the eyes; to suck, from time to time, a peppermint lozenge, or some slices of orange or lemon, which have the effect of moderating the ptyalism, that water in the mouth, which precedes the vomiting. These means succeed in a large number of cases, although it must be confessed that in others they do little or no good. Dr Armand has employed many of the remedies so pompously announced, but has never met with one which could be called a specific in the proper sense of the word.—'Gazette Médicale de Paris,' and 'Edinburgh Medical Journal.'

PARISIAN MEDICAL INTELLIGENCE.

Amongst the various subjects bearing on Medicine, introduced to the notice of the Academy of Sciences on Monday, the 10th inst., one of the most interesting perhaps at the present moment is a detailed account given by Signor Vella, of Turin, of certain experiments undertaken by him in connection with the effects of woorara administered to animals after the ingestion of poisonous doses of strychnine. These researches, which seem to have been carefully and conscientiously prosecuted, go a long way to prove that these two drugs, strychnine and woorara, stand one to the other *almost* absolutely in the relative positions of poison and antidote. (The reserve implied by *almost* is necessary, as it will be seen that this neutralizing property possessed by the woorara can be relied on within certain limits only.) The Author of the above communication informed the Academy that he was first led to administer woorra in the treatment of tetanus by the consideration of certain experiments by M. Claude Bernard, in which it was clearly established that the physiological effects of this poison on the animal economy were due to paralysis of the motor nerves. For several years past, therefore, Signor Vella has been occupied in investigating the question of the curability of tetanus by woorara. This special therapeutic action clinical observation certainly denies to this agent, and Signor Vella has of late given to his researches a somewhat different direction, and has undertaken ninety-seven fresh experiments, partly with a view to the possibility of rendering the ingestion of strychnine innocuous by subsequent injection into the blood of solutions containing woorara, partly with a view of ascertaining in what proportions and to what extent the two drugs administered *conjointly* could be taken without the poisonous effects of *either* being manifested. In the first class of investigations, then, the animals, generally dogs, were poisoned, or at least made to swallow a dose of strychnine known to be fatal to them under ordinary circumstances, and then small quantities of woorara were from time to time thrown into the jugular vein whenever tetanic symptoms showed themselves, until the toxical effects of the first agent were exhausted, and complete recovery of the animals took place. In the second category, the two poisons were mixed in certain determined proportions, and no effect whatever was produced, and the life of the animal was unaffected. A specimen of each suffices to illustrate Signor Vella's mode of proceeding. In a first experiment, the solution of two-fifths of a grain of hydrochlorate of strychnine in six drachms of distilled water was injected into the stomach of a middle-sized dog fasting, with the effect of producing at the expiration of a quarter of an hour violent tetanic convulsions. A solution of woorara was then thrown into the jugular vein; this produced a temporary cessation of the muscular spasm. When the convulsions returned, the injection was resumed, and continued at intervals until a dose of three-fifths of a grain of woorara, dissolved in half an ounce of water, had been taken into the circulation. The whole operation lasted three hours, and at its termination the dog was allowed to run about the laboratory, apparently quite well, and no return of the tetanic symptoms occurred subsequently. Three days were now allowed to elapse, and the same dose of strychnine was exhibited to the same animal, who was then left to his fate, and died sixteen minutes after its administration. In an experiment of the second class, into the jugular vein of a big dog is injected a mixture containing one-thirty-third of a grain of strychnine, and a quarter of a grain of woorara, dissolved in fifteen minims of water, and the operation is followed by no bad result whatever; but on a subsequent injection of the same dose of strychnine, not guarded by woorara, the animal is killed in the space of ten minutes. It has been proved by Signor Piria, a chemist at Turin, that on the mixing together of these two agents no new chemical combination takes place, nor is appreciable alteration noted, the two drugs preserving their individualities indefinitely—a fact which renders their *modus operandi* in the process of mutual neutralization all the more obscure, the natural conclusion at first sight being that their harmlessness when mixed was owing to the formation of a new and insoluble salt.

Did you ever hear of the *Bombyx processionarius*? If not, so much the better; for, according to M. Champouillon, it seems to be a very bad beast, and a most disagreeable acquaintance. It is a caterpillar, wearing a yellow uniform (like a Neapolitan galley-slave), of Druidical tenets, for it lives on, and no doubt worships, the oak. And, as this naturalist observes, "Si avec une gaule très longue on démolit un nid de bombyx"—or, Anglicè, if you stir him up with a long pole, he vindictively projects to a distance, in the direction of the aggressor, a very fine powder of so irritating a nature as to cause a papular eruption on the skin, followed by swelling of the part, and general febrile disturbance, with occasional delirium. A patient seen by M. Champouillon, who had incautiously applied some leaves covered with portions of the nest of a bombyx to that use which it was formerly the special privilege of the *Grub* street literature alone to fulfil, was in a high fever, with delirium, and presented on the skin of the neighbourhood of the anus a papular eruption, with considerable œdema and tenderness of the surrounding parts. I conclude that this *backbiting* insect must be unknown in our forests. I do not remember any mention of this particular bombyx in Mr White's account of the Selborne zoological productions. I may as well state that salt-and-water ablutions, and poultices of crushed parsley, are considered by M. Champouillon as being the best applications for removing the irritation produced by the noxious emanations of this *noli me tangere* of the insect world.—'Lancet.'

BIRTHS.

CRONIN.—September 25, at York terrace, Queen's Town, the wife of James D. Cronin, M.D., Surgeon, H.M.S. 'Bulldog,' of a son.

DEATHS.

ALEXANDER.—August 7, at Calcutta, of cholera, after only seven hours' illness, William Alexander, Staff Assistant-Surgeon, Army, aged 24.

BANKS.—September 14, at 69 Navy row, Stoke, Devonport, after a few hours' illness, Anthony Collins Banks, late of Saltash, Surgeon (in practice prior to 1815), formerly Surgeon R.N., aged 75.

BEALE.—July 21, at M'Carthy's Island, Gambia, of African fever, Thomas Chaytor Beale, M.D., M.R.C.S. Eng., Staff Assistant-Surgeon, Army, aged 30.

CROFT.—September 20, Charles Ilderton Croft, of Laurence Pountney hill, Cannon street, F. and M.R.C.S. Eng., L.S.A. Lond., aged 48.

DONOVAN.—July 23, at Buenos Ayres, Cornelius Donovan, M.D., aged 42.

GODDARD.—June 26, at Brisbane, Queensland, Australia, Leonard Goddard, Student and Prizeman of St Thomas's Hospital, aged 22.

LAROE.—September 24, at 23 Russell place, New North road, Islington, Charles William Sadler Large, M.R.C.S. Eng.

M'RAE.—September 21, at Kirkliston House, N.B., John M'Rae, M.D., Surgeon R.N.

MAGRATH.—September 10, Nicholas Magrath, of Le Manoir, Lefebvre street, Guernsey, M.D. Erlangen, L.R.C.P. Edin., F. and M.R.C.S. Eng., Surgeon R.N., Admiralty Surgeon and Agent, &c., aged 57.

OSBORNE.—September 9, Thomas Osborne, of Northampton, Surgeon (in practice prior to 1815), aged 71.

PARKES.—August 28, of consumption, after a lingering illness, Thos. Parkes, jun., M.R.C.S. Lond., aged 22.

PRICE.—September 19, at Tyne Hall, Ilford, Essex, Rees Price, M.D. Heidelberg, M.R.C.S. Eng., formerly Surgeon R.N., aged 80.

RAMSAY.—June 10, at Dobroyde, New South Wales, David Ramsay, M.D., aged 66.

WESTON.—September 14, at Camberwell, Edward Joseph Weston, late of St Mark's crescent, Regent's park, L.S.A. Lond., formerly Surgeon to the Royal Humane Society, &c., aged 51.

WHITFIELD.—September 9, at Biggar, Lanarkshire, Peter Prenderleith Whitfield, A.M., M.D., aged 24.

WOODMAN.—September 22, at East Leigh, Havant, Hants, Jas. Woodman, M.D., aged 76.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen, having finished the course of examinations, were admitted Licentiates of the above College during the recent sittings of the Examiners:—William Goldie, Lanarkshire; Robinson Hudson, Sunderland; James Mackie, Aberdeenshire; *Alexander Milne, Forfarshire; John Rayner, Warwickshire; Robert Bird Selby, Portobello; *Robert Wallace, Cape of Good Hope; James Watt, Aberdeen; John Ullathorne, Darlington; *David M'Cheyne Young, Kelso. [Those gentlemen to whose names an asterisk is prefixed, also obtained the diploma of the Royal College of Physicians.]

APPOINTMENT.—Mr C. F. Maunder has been elected fourth Assistant-Surgeon to the London Hospital.

MEDICAL BENEVOLENCE.—We hear that the Council of the Medical Benevolent Fund—as the result of their direct appeal to the Profession for aid in place of the biennial dinner—have obtained in answer to their call, after paying all the expenses, the handsome sum of 350*l*.

South Staffordshire Hospital. — On the 12th ult. a general board of governors of this charity was held at the hospital. The Secretary (Mr Smith) read a letter from Dr Topham, resigning his office as physician.—Mr Fowler moved the following resolution: "That this Board, in accepting the resignation of Dr Topham as one of the Physicians of this hospital, desire to express their sympathy with him under the circumstances which have deprived the institution of his valuable services, and at the same time to record their high sense of the distinguished ability with which he has discharged the onerous duties of his office, and to offer him their most grateful thanks for his long and faithful services. That Dr Topham be appointed Consulting Physician to the South Staffordshire General Hospital." In a brief but excellent speech, Mr Fowler hoped that the resolution would not be considered as a mere formal proposition, and said that the Board would feel that he was not going beyond what was proper in urging the vote of thanks in rather strong terms, when they recollected that Dr Topham had served the institution from its foundation in 1849, and served it well, and that the cause of his leaving it was not from any difference of opinion between himself and the other officers of the institution, nor from any circumstance that the Board might regret as affecting the harmony which subsisted in the institution, but that it was owing to a cause which they must all deeply lament — namely, Dr Topham's personal ill-health. It was a remarkable feature of modern civilisation that the poor in time of sickness were able to get the best medical skill, and the debt that was owing to the medical gentlemen on this account should never be forgotten. It was an easy thing for a gentleman to subscribe towards a charitable institution, or to devote himself to its regulation; but it seemed to him to be the noblest charity that could be conceived for gentlemen whose professional ability was really their living, and whose time was almost more valuable than money, to devote their time and professional knowledge without reward to the service of the poor. As to Dr Topham's retirement from his office, it was not only a misfortune for the hospital, but also a town's loss. The Board deeply regretted it; but if they carried the resolution there would still exist a tie of friendship between Dr Topham and the hospital, and at times it would receive the benefit of his valuable aid.—Mr W. H. Rogers, in seconding the resolution, said he had been connected with the hospital a little longer than Mr Fowler had, and he could truly say that he did not think any man had ever been connected with an institution of the kind who had done his duty more faithfully to the patients, or worked more cordially with the board of directors, than Dr Topham. He would not allude to bygone days, lest he should remind them of some unpleasantness that once took place; but he might say, there was a time in particular when Dr Topham, by the great cordiality with which he supported the Board, rendered very essential service. He could assure the meeting that he never seconded a resolution with more cordiality than the one now before them.—Mr Cartwright also bore testimony to the great value of the services which Dr Topham had rendered to the hospital. — The resolution was then put and carried.

A Trade Nuisance.—On the 14th of August last I received complaint of a trade nuisance, perhaps more offensive in its character than any other that is carried on in the district. It is concerning a gut-cleaning establishment in Round court, Cow Cross street. The complainants, Messrs Chubb and Sons, the locksmiths, of St Paul's Churchyard, who employ about eighty men in their workshops on the opposite side of the court, state that "the stench from the manufactory in question is generally offensive, and at times most overpowering, causing sickness among their workmen." Their foreman also informed me that the men frequently had to retire from the workshop for half an hour at a time. I should premise that Round court is a small one, containing only nine houses, which are defective in a sanitary point of view, in consequence of having no thorough ventilation or back yards; the waterbutts and closets being placed in the cellars. They are thickly inhabited by working men, who all complain of the trade in question. It is carried on by Mrs Norman and her sons, and consists in receiving the intestines and bladders of oxen and sheep, in separating the fat which the butchers have left adhering. This fat serves to make soap or very inferior tallow. The guts are then emptied by running water through them; afterwards, in order to cleanse and detach the slimy mucus from them, they are steeped in a weak solution of alum and soda. The workman then inflates them with his mouth, and hangs them up in the sun and wind to dry. It is this part of the process, I believe, that gives the neighbours so much annoyance, as it saturates (I might say, poisons) the very air that they breathe with moisture not of the most wholesome or savoury character. They are then sold for the purpose of covering preserves and pickles. When a finer tissue is required, as an envelope for sausages, or to be spun into cat-gut, violin and other musical strings (as is done at two manufactories in Sharp's alley), a much more offensive process of preparation has to be gone through, the guts requiring to be kept until they are in an advanced stage of putrefaction. It is difficult for any one who has not visited these establishments to form any idea of the horrible stench that pervades and emanates from them. It was with reference to these two manufactories, that in making a return to the House of Commons, in 1858, I reported that the nuisance necessarily arising from them could not be satisfactorily remedied. One of the great sanitary advantages—and there are many to arise from the formation of a spacious central meat-market in West Smithfield—is, that we shall get rid of these analogous noxious and offensive trades. —Dr Gibbon's 'Report to the Holborn Board of Works.'

A New Coroner's Court, provided by the Corporation, has been recently opened in Liverpool.

The first medical charity of South Africa supported by voluntary contributions is about to be established in the shape of a dispensary at Cape Town for the relief of the sick poor.

Amongst the Staff of the Papal Irish Brigade are returned the names of Nicholas G. Whyte, M.D., Surgeon, and Philip O'Flynn, M.D., Assistant-Surgeon.

A Seat at St George's.—In front of St George's Hospital, Hyde-park corner, a seat for tired pedestrians, within a railed space, has been conveniently placed, and is much used.

Hospital Rags.—Thrift has reached such perfection at Calcutta, that, as stated by the 'Friend of India,' "even hospital rags are now washed, and sold by tenders to the paper-manufacturers.

Death of Dr Roscher.—Dr Roscher, one of the most enterprising of African explorers, has been attacked in the night by two natives, at one of the large inland lakes in the western part of Zanzibar, and killed in his bed by a poisoned arrow. The murderers have been brought to justice.

Recently, Daniel de la Cherois Gourlay, physician, was indicted for a breach of trust, as executor, in misusing money belonging to the widow of a testator. He was convicted, and sentenced to six months' imprisonment. "A most unjust sentence, my Lord and Jury," said the convict.

Essex and Colchester Hospital. — A most suitable gift has been made to this institution, through the forethought and exertion of Mr Caldell, of St Peter's Vicarage. It consists of 200 volumes of books, which will be issued to the patients under the direction of the Committee of Management.

A Public Gymnasium, with all the necessary hygienic apparatus, has been presented to the city of Glasgow by Mr David Fleming, of Manchester, and was last week formally handed over to the Lord Provost and the magistrates of the city, and thrown open to the public.

Lewis's Medical Library.—Mr Lewis has undoubtedly conferred a great boon on the members of our Profession by the establishment of his valuable Medical Library. Here, without trouble or delay, every new medical work may be obtained, as soon as published, at a merely nominal subscription annually. This library, while it makes no pretensions to a complete medico-bibliographical history, such as we pride ourselves in possessing in the library of the College of Surgeons or the Medico-Chirurgical Society, offers to the Profession unusual facilities for the consultation of all our modern and new works. Having perused Mr Lewis's catalogue, we are satisfied of its value, and cordially recommend it to the notice and support of our medical brethren. Such a library was much wanted.

The Sanitary State of the West India Islands.—The accounts lately received by the 'Shannon' represent these islands to be generally healthy. There has been some fever at St Vincent's, and also at Belsize, but not resulting in many deaths. St Thomas' is very healthy for the season of the year.

The Health of the Army in China.—The 67th Regiment has but one per cent. on the sick list. The sanitary arrangements are excellent. There is no foul smell about the camps, which vie with each other in cleanly neatness. The natural consequences have ensued. There are but 13 officers and 648 men on the sick list out of the 12,000 composing the force. With the exception of 116 cases on board the hospital-ships, the diseases are of a very trivial character. This speaks volumes in favour of Dr Muir and the Medical Staff, and particularly of Dr Rutherford, who is charged with all local sanitary arrangements.

The Cholera continues to make numerous victims in Spain. This mysterious scourge observes no order in its progress, attacking one province and sparing another, without anybody being able to assign a cause for its presence in one place rather than in another. It is at present at Toledo, where fifty persons have been attacked within a few days. It is to be remarked, however, that the disease is decreasing in intensity. Thus, the deaths are diminishing by nearly one-half. Of one-hundred persons attacked, not more than five or six die.

The Cholera at Gibraltar.—The cholera, which has long hovered over Spain, and from which Malaga has been free but a fortnight, has passed the frontier and reached Gibraltar. The same despatch which brings this ominous intelligence adds the cheering statement that "every precaution that sanitary science can suggest to prevent the further spread of the epidemic has been adopted by Sir William Codrington, on the advice of the principal medical officer, Dr. Paynter." No doubt that able medical officer will suggest precautions as to the feeding, clothing, and exercise of the healthy, and the segregation of the sick, which will be attended with useful results. The statement would, however, convey a far more solid sense of security to the mind of the well-informed medical reader if he were not obliged to reflect that in respect to the origin and mode of extension of those terrible epidemic diseases, Asiatic cholera and yellow fever, the medical world is still at issue, and have not yet been able even to agree upon so important a question as the communicability of these two diseases. Dr. Bryson, Inspector-General of Hospitals, R.N., in a preface to a recent 'Report on the Health of the Royal Navy,' forcibly illustrates the evils resulting from the want of consistency and uniformity in the opinions held respecting the means to be adopted when either malady makes its appearance in a ship of war. While one class of medical officers, assuming that the disease, like small-pox and measles, spreads by infection, recommends the segregation of the sick from the healthy, and a change of locality with improved ventilation; the other, believing that it is the offspring of some unknown cause of an atmospheric nature, or of offensive matters contained in the holds, recommends the latter to be cleared out on the spot, and the sick to be removed on shore, whether the disease may or may not be prevalent amongst the inhabitants. Dr. Bryson remarks that it is clearly evident that one of these modes of procedure must be wrong, or at all events superfluous; for if the disease does not spread by infection, the separation of the sick from the healthy can do no good, but, by creating unnecessary alarm and confusion, may cause considerable evil. But if it does spread, like small-pox and measles, by infection, then a heavy responsibility rests with those who recommend measures which can only tend to its extension, and the destruction of probably a third of the ship's company, and possibly hundreds of the population on shore. This kind of commentary is far from reassuring to the civil population, or complimentary to medical science; but it is necessary to face our deficiencies if we would supply them. In no matter do we require more definite facts on which to build a system of treatment than in relation to Asiatic cholera—that terrible epidemic which now sets at nought our science in much that pertains to its origin, its progress, and its cure.—'Lancet.'

Death from Chloroform.—A patient named Carrell died at the Northampton Infirmary on Wednesday week, from the administration of chloroform. Deceased had been lodging in Commercial street, and went to the Infirmary on Saturday week, with the determination of having a tumour taken out of his back, which had caused him some little annoyance for several years, and which he had been informed would some day prove fatal if allowed to take its own course. This had been repeatedly pressed upon deceased by his fellow-workmen at Mr Mulliner's, coachbuilder. Under these impressions the poor man went to the Infirmary on Saturday week, where he was dieted until the Wednesday morning, and then taken to the operating-room for the

purpose of having the tumour extracted. Mr Gray and Mr Mash were present, to whom deceased expressed a wish that chloroform might be administered before the operation commenced. Mr Mash did not think it necessary to use chloroform, and therefore explained to Carrell the nature of the operation, telling him that it would not be very painful or very dangerous; but deceased still persisted in his wish. Mr Mash therefore consulted Mr Ashdown (as is usual), and requested that gentleman to examine the deceased, to ascertain if he was able to bear the effects of chloroform. Mr Ashdown said there was no danger, and accordingly the House-Surgeon, Mr Gray, was instructed to administer the anæsthetic, which he did, the chloroform being given on a handkerchief. Its effects were soon visible upon deceased, who duly became insensible without anything unusual being observed, although he was closely watched. On removing him into a proper position for performing the operation, it was observed that his countenance was very much changed. The suspicions of the operators were at once roused, and immediate steps were adopted for bringing the man to his senses again, instead of commencing their surgical operation. Water and other restoratives were resorted to, but all to no purpose. Artificial breathing was then tried; but this too was unavailing, and after an hour's futile endeavours at restoration, the deceased was reluctantly given up as lost. An inquest was held at the Infirmary on Thursday, before Mr E. P. Hicks, county coroner (acting for Mr J. Becke), and a respectable jury, on the body. Mary Carrell was the first to be examined, and said the deceased was her husband. He was 42 years of age. He first perceived the tumour about nine years ago, and often talked of having it taken out. It originated through a blow inflicted by a policeman in Liverpool, when deceased was under the influence of drink. He had only been in Northampton since March last. Messrs Gray, Mash, and Ashdown were also examined, all of whom stated that they had known patients to inhale double the quantity of chloroform that had been administered to deceased without any dangerous effects resulting from its use. Every precaution had been used by them in this as in former cases, and it had been administered to hundreds with perfect success. They could not account for this unusual occurrence, but had no hesitation in saying that deceased had died through the effects of chloroform. A post-mortem examination had been made by Messrs Mash and Gray, in presence of the Medical Staff, and it appeared that deceased had been a man given to drinking habits. His brain, heart, and lungs were very much congested. The jury, without any consultation, returned a verdict "That deceased's death was caused by chloroform duly administered. They also begged to state that, in their opinion, the Surgeons were entirely free from blame in the matter, as it appeared to them that the proper caution had been taken when administering the chloroform."

APPOINTMENTS FOR THE WEEK.

Wednesday, October 3.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

OBSTETRICAL SOCIETY OF LONDON.—Dr Tilbury Fox, "On the Pathological Lesion of Phlegmasia Dolens;" Short Papers by Drs R. N. West, Battye, &c. 8 p.m.

Thursday, October 4.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.

London Home.—2 p.m.

Friday, October 5.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, October 6.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, October 8.

Operations at the Royal Free Hospital, 2 p.m. Metropolitan Free Hospital, 2 p.m.

Tuesday, October 9.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

*** The publication of the MEDICAL CIRCULAR has been delayed one day to enable us to give our readers a Report of the Introductory Addresses.

IOTA.—No gentleman is justified in taking a case under the circumstances stated. It was undoubtedly contrary to the etiquette of the Profession.

H. L.—A Medical College and Licensing Board exist in Australia; but there is no prohibition upon practice.

CHIRURGUS (Hornsey).—Yes.

Dr J. S.—The copies shall be forwarded.

Dr E. BROWN is thanked for his kind words.

A SUBSCRIBER.—The newspaper has not been received; otherwise the subject would have been noticed.

AN ALIENIST'S letter on the Colney Hatch case, received.

Mr BLAKE.—We are unable to give the information required.

H. E. W.—1st. No.—2nd. No.—3rd. No.

A SUBSCRIBER FROM THE FIRST.—Either King's College or St Bartholomew's.

VIGIL'S letter has been received.

Mr NICOLSON.—Received and inserted.

Dr EBEN WATSON has written to us a letter complaining of a foot-note to a report on Hæmatocele, which appeared in this Journal on August 15th. The remark of which he complains is, that he was charged with not having sufficiently studied Mr Baker Brown's cases of vesico-vaginal fistula; and he refers to his article in the 'Medical Times and Gazette' of June 23rd, in proof that he is, and was, fully acquainted with Mr Brown's cases. We regret that an apparent injustice should be done to Dr E. Watson. That gentleman, however, is mistaken in supposing that the article was written by Dr Jones: it was contributed by our late Reporter.

W. P.—There is no feeding-bottle we have seen that will bear comparison with Mr Cooper's, of Oxford street. See and judge for yourself.

ENQUIRER.—Waters' quinine wine appears to be an elegant mode of administering this valuable tonic. We believe it to be carefully and purely prepared, much approved of, and well deserving notice.

Mr STREATFIELD.—Note received.

A MEDICAL STUDENT (Newcastle.)—1st. We presume that you would be eligible for examination, but you should communicate with Mr Belfour, Secretary to the College of Surgeons.—2nd. Yes.

Mr ROBT. STEVENSON is thanked for his note.

Mr FREDERICK AUGUSTUS HARDY (Junior United Service Club) has written to us to complain of the unprofessional conduct of a London Surgeon (named by him) who, he says, performed an operation upon him for some rectal disease whilst he was suffering from concussion of the brain; but his letter is so brief and inexplicit, and the circumstances so peculiar, that we cannot satisfactorily comprehend the grounds of so serious a charge.

PULVIS JACOBI *VER.*, NEWBERY'S.

GENTLEMEN,—We beg to call your attention to the following paragraph by "*J. Cheyne, M.D.*, Physician to the Hardwicke Fever Hospital, Dublin, *in his paper on 'the virtues of James' Powder in the Apoplectic Diathesis*:"

"She began a course of James' Powder in the latter end of September: the first night she took only two grains, and every succeeding night an additional half grain, till the dose amounted to twenty grains. She took *twenty grains every night for five weeks*, when she found herself so well that she discontinued the medicine."—"*Dublin Hospital Reports*," *vol.* 1. *p.* 319.

To secure the dispensing of the *original* preparation, which, for 114 years, has been sold by the Newbery family in St. Paul's Churchyard, it is necessary to prescribe it as "*Pulvis Jacobi Ver., Newbery's*," otherwise another article (wanting in the best properties, and recommended to be given in a different code of dose, *though called by the same name*), will be substituted for the original medicine. This, of course, cannot but have an effect other than that expected, and will thereby lead the practitioner totally to discard it from his daily Pharmacopœia, as a preparation whereon no dependance can be placed. We hope the above extract will prove that when the genuine medicine is used, faith may be reposed in it.

Yours faithfully,

F. NEWBERY & SONS.

45, St. Paul's Churchyard.

Liquor Castanea Equina.—Messrs. REW and Co. respectfully solicit the attention of the Profession to this Preparation of the Horse-Chesnut; taken internally for Rheumatic Gout and Rheumatism, it is a safe, agreeable, and most efficacious remedy.

Dose, two to four drachms. Price 12s. per pound.

The Oil of Horse-Chesnuts applied externally for enlarged and stiff joints, acute or inflammatory pain of any kind, gives almost immediate relief.

These genuine Preparations of the Horse-Chesnut are prepared only by REW and CO.

LITHIA WATER, LITHIA POTASH, and LITHIA AMMONIA WATER. These Waters are prepared according to the Instructions of Dr Garrod, and each bottle is guaranteed to contain the proper proportion of Lithia. 5s. per doz.

R. M. REW and CO., Operative Chemists, 282 Regent street, London.

NEW REMEDIES
BY SAVORY AND MOORE.

HYPOPHOSPHITE OF QUININE,
SYRUP OF HYPOPHOSPHITE OF QUININE AND IRON,

which have been employed with highly satisfactory results in debility and low vitality.

CARBONATE of LITHIA; Hypophosphite of Lime, Soda, and Ammonia; Syrups of Phosphate of Iron, Lime, Manganese, &c.

GENUINE MEDICATED COD-LIVER OILS (introduced by Messrs Savory and Moore) are also prepared in the Laboratory, 143 New Bond street, London.

THE NEW EYE DOUCHE,

invented by SAVORY and MOORE, has elicited the approbation of the most eminent Oculists. Vide 'The Lancet' of March 31st.

Gentlemen's Inverness CLOAKS and OVERCOATS in great choice, made of the Highland Hand-loom Tweeds. Also BLACK and OXFORD MIXED TWEEDS for Clergyman's wear. Patterns sent to the country free.
SCOTTADIE, 115 Regent street, corner of VIGO STREET, London.

Flour—(Essex)—Warranted free from adulteration, to any part of London (not less than 14lbs.) carriage free. Whites, for pastry, per bushel (56lbs), 11s. 8d.; Households (recommended for bread-making), 11s.; Seconds, 10s. 4d.; Wheat Meal for brown bread, 10s. 4d. Best fine and coarse Scotch Oatmeal. Address HORSNAILL and CATCHPOOL, Bulford Mill, Witham, Essex, or 97 Goswell road, City road, E.C. Directions for bread-making gratis. Terms Cash. A half-sack delivered free to any rail station 200 miles. German Yeast.

DINNEFORD'S
Pure Fluid Magnesia, now greatly improved in purity and condensation.

"Mr Dinneford's Solution may fairly be taken as a type of what the preparation ought to be."—'Pharmaceutical Journal,' May, 1846.

This excellent remedy, in addition to its extensive sale amongst the public, is now also very largely used in the stone jars (half-gallon, 5s. 6d.; gallon, 9s. 6d.), specially adapted for the use of Surgeons and Chemists. To be had from the Manufacturers,

DINNEFORD and CO., Chemists, 172 Bond street, London; all Wholesale Druggists and Patent Medicine Houses.

The Pulvis Jacobi Verus, prepared by WILLAM HOOPER, 24 Russell street, Covent garden, from its identity with the more costly preparations and its acknowledged efficacy as an Antimonial, merits the patronage of those Gentlemen who have not hitherto included Pulvis Jacobi in their daily Materia Medica. An extensive continuous demand, for Public Institutions, has satisfactorily verified the ancient character of this medicine. It is sold in 1 oz. and 4 oz. bottles, at 2s. 9d. and 10s. 6d.; and in packets for transmission by post.

WATER BEDS AND CUSHIONS.
A Preventive against Bed Sores, &c. Bed Sheets, Air Cushions, and all necessary Utensils for Invalids.

BENHAM and Co.,
Practical India-rubber Workers, 118 Oxford Street, W.

Board.—A Medical Man, residing in the NEW TOWN, EDINBURGH, can receive into his Family Two young Gentlemen as Boarders. Terms, from £50 to £70 (per Session of Nine Months).—Apply to "M. M.," Medical Circular Office, 20 King William street, Strand, W.C.

CLINICAL LECTURES.

ON INJURIES OF THE EYE-BALL BY BURNS, SCALDS, &c.

By HAYNES WALTON, F.R.C.S.,
Surgeon to St Mary's and to the Central London Ophthalmic Hospitals.

The surface of the eye is liable to be injured by heated liquids, by explosions of gas, gunpowder and other inflammable compounds, and by glowing or molten metal, all of which are generally projected with violence. Yet it enjoys wonderful immunity from ordinary burns and scalds which more or less overspread or involve the face and head, by virtue of the involuntary closing of the eyelids, and the instinctive tendency to maintain them shut. It would be a work of time to attempt to describe the several conditions that are met with, varying, as they do, from simple redness to charring or calcination. It is enough to point out that the most general effect is manifested in the conjunctiva, which may be much swollen and inflamed. There can be no mistake about the nature of the injury, and the treatment is comprehended in a few simple rules.

Tepid bathing with the eye douche or syringe is the first general measure, not only to soothe and comfort, but to remove any extraneous material. After this, diligent search should be made to ascertain if anything has intruded. When the cornea or the conjunctiva has been abraded, more comfort is imparted by the application of glycerine than anything else I know of.

Not the least important of all, and it is important in proportion to the extent of the damage, especially when the cornea is hurt, is to keep the eyelids closed. By this we exclude the air, ensure moisture and warmth, and maintain the parts in quietude. Anodyne, soothing applications, and a strict daily attention to cleanliness, are among the necessaries. The eyelids should not be allowed to get gummed together, that there may be free exit to any discharges; and this is best accomplished by cutting off the cilia and keeping their edges greased. I do not think that surgical skill is available topically, beyond this. I suspect that the introduction of stimulating and astringent ointments and lotions, of all kinds, is injurious by increasing irritation. If the vitality of a part has been destroyed or a wound inflicted, a definite process of repair must be passed through, which, I think, cannot in general be better assisted or directed than by the means mentioned.

Bodily rest and attention to constitutional symptoms are too often overlooked, and neglect of them may bring the penalty of prolonged suppuration or inflammatory action of the entire eyeball. What is to be most feared when the accident is severe, next to the loss of sight, is from contraction and adhesion of the eyelids to each other, or to the eyeball; inevitable conditions accordingly as the conjunctiva is lost, or the angles of the eyelids injured. Cicatrisation cannot be effected without it; and the quicker this is brought about, the less will be the defect.

The prudent course is to endeavour to reduce the healing process to the shortest limit, and afterwards to attend to the adhesions.

The slight injury that particles of melted metal generally inflict is a matter of marvel. I might fill pages with the wonderful escapes that are recorded, the greater number of which relate to the entrance of lead that had moulded itself to the surfaces of the eyeball and the eyelids, thereby showing that it had entered in a fluid state. A theory has been suggested to account for this, but I do not think it sufficiently satisfactory to be related.

In the last occurrence of the kind that I saw, many of the cilia of both the eyelids were soldered together with a lump of solder, and the eye could not be opened till they were cut off. The edges of the eyelids were severely singed.

The following remarkable accident from molten iron is recorded in the 'Ophthalmic Hospital Reports,' page 217. A very healthy man was employed in an iron-foundry. While at work, some of the molten metal at a white heat had been spirted into his left eye. It struck the eyeball over the lower edge of the cornea and the adjacent part of the sclerotic coat. One of his fellow-labourers removed the metal with some difficulty after it had solidified, on account of its adhering firmly to the charred tissues. It had in cooling been accurately moulded to the surface of the eyeball and to the edge of the lower eyelid. The affected parts of the cornea and sclerotic, which included the greater part of the thickness of each, sloughed off, as also did some of the palpebral mucous membrane. The eyeball itself, however, did not inflame. In the healing of the scar, the pupil was drawn downwards by puckering of the iris at its attached margin, but union was retained. Some adhesions between the eyeball and the lower eyelid resulted, but they did not constitute any material deformity nor occasion much inconvenience.

Burns and scalds of the eyelids are generally followed by very distressing contraction, from the thinness and looseness of the skin, and the mobility of the tarsi. Paramount attention is therefore required to prevent or to lessen the suppurative stage. Of all applications that I have myself tried and seen used, none are equal to nicely-dressed cotton-wool; it is soft, light, and cleanly. It should not be applied in a lump, but put on in minute bits and pressed with a probe so as to make it smooth and uniform. Where there is merely an abraded surface from loss of cuticle, it excludes the air and soaks up any superfluous secretion. If suppuration should exist, it absorbs the superabundant fluid, while enough is left for the purpose of sufficient moisture. With it the sore does not grow flabby and indolent, requiring stimulants, as so frequently happens with water-dressing, and the granulations are kept in a condition that precludes the necessity for escharotics. I have frequently seen ordinary ulcers that had resisted other applications heal under this, the simplest of all means. The changing of the material is readily effected. Any portion adhering to the sound skin must be wetted, and that over the raw surface will always readily separate when surcharged with moisture. Should a mild astringent ointment seem requisite, the Pharmacopœia supplies many to choose from. No method of treatment that is known will prevent subsequent contraction, if the true skin, the *cutis vera*, be much damaged or destroyed; and all that can then be done towards lessening the deformity is to shorten the period of suppuration. When the injury is superficial and small, it may be well to endeavour to obtain incrustation and healing of the raw surface by the modelling process of Macartney, which may be effected by unirritating powdered substances, or brushing it over with nitrate of silver, and covering all with goldbeaters' skin or gum, in preference to collodion, which is too painful an application. Professor Miller of Edinburgh has used successfully a thick, semi-fluid, aqueous solution of gum tragacanth: he lays it gently and uniformly on the raw surface, and reapplies it, should any portion become imperfect. Being transparent, complete surveillance of the part is permitted. Should these means not prove successful, the parts are not in a less favourable condition for other treatment. It is better not to cut blisters, for the cure goes on more readily when the fluid is absorbed and the cuticle not broken. A greasy application of any sort is useful, for the cuticle will remain longer unbroken under it.

The special indication arises, if the edges of the lids be involved, to prevent their edges from uniting; and this may be with certainty fulfilled, if the corners have escaped injury.

What is to be done when grains of powder, or the residue of powder, enter the skin of the eyelids? I have never seen a person sufficiently early after the accident to warrant any attempt at removal. A great authority, Dr Mackenzie, advises the particles to be carefully picked out, one by one, with a cataract needle; an operation, as he remarks, that may take hours to accomplish. He adds that we should not trust to the application of a poultice, which is recommended with the view of dissolving and bringing away the grains of powder.

I think that any determination of "picking" or not interfering should be decided by the amount of powder that had entered: if much, I should leave it alone; if slight, I should probably do my best to remove it, and especially if there were grains sticking superficially in the cornea or the conjunctiva. I doubt whether but a small portion of any individual particle can actually be removed from the latter structure without excision of a part of it: this would be unjustifiable.

I have lately seen a recommendation, in a French journal, to apply violently-stimulating lotions to the surface directly after the burn: strong solutions of corrosive sublimate, for instance, for days together. This produces a violent eczema, by which epidermic scabs are raised, and the gunpowder also more or less with them.

Which of the two, the remedy or the disease, is the worse, must occur to the mind of the reader!

ECCHYMOSIS.

The ready production of ecchymosis about the eye is, of course, due to the superficial position of the bones of the orbit, and the contusion that the skin receives from a slight blow; while the considerable tumefaction which is so common after any blow is due to another peculiarity of the orbital region—the looseness of the skin.

I question whether any means, except gentle friction, can hasten the natural process of absorption. The employment by pugilists of briony root and Solomon's seal, scraped and made with bread into a poultice, or of rosemary and arnica infusions, has induced medical men to recommend these applications. The tincture of arnica and water is the present popular remedy for all bruises.

But it is not, I suspect, a fact that the prize-fighters can disperse these results of their savage encounters; and I believe they last in them as long as in other people: but as their accustomed personal exhibitions after fights are at night and by gas-light, most of the colour, especially the lighter hues, are invisible, and hence the popular assumption of the potency of their remedies. If it be true that in them the extravasation is quickly dispelled, it is more probably owing to their youth, and to the perfection of the nutrient and absorbent processes which exist in their high bodily condition.

There does not appear to be satisfactory evidence that depressing the temperature of the surface by frigorific mixtures hastens absorption; and, theoretically speaking, I should rather expect it to retard Nature in her operation.

There are, however, degrees of ecchymosis, some of which demand treatment, and neglect of which may be followed by injury to the eyelid. The extravasation may be increasing; the infra or supra-orbital vessels, or other arterial twigs, may continue to ooze, and recourse must be had to pressure, or cold, or the heart's reduced action by the loss of blood,

or by a smart purge, and, above all, perfect rest.

When the extravasation is considerable, the probability of suppuration is to be borne in mind, and the state of the system must be looked after, and all febrile threatenings attended to. Neither incisions nor punctures should be made with the intention of turning out coagula; for suppuration would be almost certain to follow. The knife should be withheld, unless there is suppuration or erysipelatous inflammation, or sloughing is impending or has commenced. Leeches on the injured part are worse than useless; they do not imbibe coagulated blood, while they add to the local injury. The feelings of the patient must sometimes guide us in the choice of local applications: when the extravasation is considerable, there may be pain which possibly will be relieved only by warm opiate lotions. Ecchymosis of the conjunctiva, as every one knows, is produced by very slight causes, such as the most trivial blow, a cough, or a sneeze. Indeed, it is not uncommon without the slightest trace of its origin. It is very persistent, but need not excite the smallest anxiety.

Even with tumefaction from extravasated blood beneath, it is not to be dreaded. I fancy that I have seen every variety of this from accidents, and after operations, especially after that for squinting; and I never have deemed it prudent in the worst examples of mere swelling to make incisions, nor have I ever regretted non-interference. I have seen the disadvantages of incision. I have known operators expect to give exit to blood, when of course they discovered it was coagulum they had exposed, and all that could escape was a small amount of serum.

My rule is to trust to Nature, and do nothing except there be pain, or heat, or any discomfort, or other conditions, when I treat the existing symptoms according to the general rules of surgery, or therapeutically, using cold, or warmth, or opiates, as may seem necessary; but I deprecate any routine of stimulants or astringents. I am often told "that patients will have something;" and my answer is, "Well, if they must be so amused, pray let them have a lotion weak enough to be harmless; but let us not lose sight of the distinction between usefulness and amusement."

ON THORACENTESIS:

ITS INDICATIONS AND COUNTER-INDICATIONS IN PLEURISY.

DELIVERED AT THE HÔTEL-DIEU,

By M. ARAN.

(Continued from page 172.)

Is it necessary that the nature of the fluid should be known before practising thoracentesis? Doubtless this is desirable in every case; but, unfortunately, it is not always easy to determine this question with precision. Only, as a general rule, remember, that in all the circumstances I have mentioned to you, the evacuation of the fluid, be it what it may, is never to be neglected.

It may happen that, while there is such pleuritic effusion as to render thoracentesis necessary, some other complication may be present, either on the part of the lungs or of some other organ. Do not lose sight of the fact, that even then the pleuritic effusion is a serious complication, and begin by first ridding your patient of that evil.

From what has been said, you must perceive that I do not make much account of any counter-indication of thoracentesis. There is one, however, which I would mention, and that is gangrene of the pleura or lungs. In cases of this kind, the fluid has properties so irritating, that, as it oozes from the wound left by the canula, it may give rise to diffused phlegmonous inflammation, which soon attains a formidable extent, and is not long in occasioning the death of the patient. Never have I seen such a state occur, not even in purulent effusions, when the fluid continued to exude by the opening in the side where the canula had been withdrawn. But serious symptoms seem inevitable when the fluid has a gangrenous odour. It was but lately, in a case of this kind, that diffused phlegmonous inflammation invaded not only the back, loins, and nates, but, at the autopsy, we could follow the purulent collections, with sphacelus of the cellular tissue, as far as the muscular interstices of the thigh and leg.

I shall next say a few words on the method of operating. That which I practise does not materially differ from the process recommended by M. Trousseau. What point of the thorax is to be preferred? It is usually said that the most dependent part should be selected; an indication I do not think sufficient, and I would say that the point where the fluid is collected in greatest quantity; and the lung the farthest from the thoracic parietes, should be chosen. Auscultation and percussion will furnish you with the knowledge necessary for settling this point of the diagnosis.

You must not look upon the cavity of the pleura as you would on that of a shut vessel, nor believe that it would suffice to make a puncture at the most dependent part in order to evacuate all the contained fluid. In the expulsion of the fluid two circumstances concur—the expansion of the lungs produced by atmospheric pressure exerted on the bronchial mucous surfaces, and the recession of the diaphragm and thoracic parietes. From the moment the lung becomes fettered with the false membranes, the thoracic parietes and diaphragm are no longer free to sink down, and the liquid ceases to flow. You perceive, therefore, how visionary would be the attempt to free the chest of all the fluid, which necessarily flows in an irregular and intermittent manner, but especially during deep inspiration and efforts to cough.

I do not pretend to describe to you all the ways in which thoracentesis may be performed: all I shall say is, that I always employ a large-sized trocar of the kind used for hydrocele. As an indispensable precaution, the outer extremity of the canula should be covered with moistened gold-beater's skin, as proposed by M. Reybord, firmly attached, and so disposed that it may allow of the easy introduction and removal of the trocar, as well as of the free expulsion of the fluid, and the non-introduction of atmospheric air into the cavity of the pleura. The patient being seated upright in bed, and the point where you would operate having been selected, an assistant, who stands on the opposite side, raises upwards the integuments, so as to obviate the parallelism that would otherwise occur between the wound in the pleura and that in the skin. While the integuments are held thus, a small wound, on a level with the upper border of the rib lying below the intercostal space to be penetrated, is made with a common lancet, through the cutis—an excellent way for saving the patient the pain he would suffer were the integuments perforated directly by the trocar, which is now to be passed over the upper border of the rib and directly into the thoracic cavity. When you feel that the instrument meets with no resistance, you know that it has penetrated the pleura. In this operation there is a point to which I must direct your attention; and it is this: take care to raise the handle of the trocar sufficiently, so as to form a right angle with the body of your patient. Without this precaution, the instrument might pass between the parietes of the chest in such a way that, though plunged in to its utmost extent, the point might not penetrate the pleural cavity. Again, do not lose sight of the fact that in certain subjects the ribs may overlap so much as scarcely to allow the introduction of the trocar, when deviation from the line to be followed might bring the point of the instrument in contact with the rib alone. When the instrument has penetrated the cavity of the pleura—the skin being still stretched upward by the assistant—the operator, holding the canula with his left hand, with his right gently withdraws the trocar, when the effused fluid begins to flow. But there are cases when no fluid makes its appearance. How is its absence, under these circumscances, to be accounted for? Either the trocar has slipped between the thoracic parietes, or, as M. Trousseau still thinks, has really pushed the pleura before it, so as to detach it from the thoracic parietes—a fact, however, which has never yet, so far as I know, been ascertained anatomically. Should the former be the case, the fact may be ascertained by the resistance which a blunt style, made of ordinary wadding, would encounter when introduced into the canula. Yet it may still happen that the instrument has entered the pleura, though no liquid make its appearance. In this case, the effused fluid, having undergone partial absorption, now forms a semi-solid jelly; or false membrane may obstruct the internal opening of the canula, preventing entirely the escape of fluid.

The fluid seldom flows in a continuous jet, but is intermittent and unequal, and most abundant when the patient coughs, which he seldom fails to do towards the end of the operation, when the cough becomes very painful. This shows that the lungs begin to expand, and that air penetrates to the remotest bronchial ramifications, previously so compressed by the effused fluid as to become impermeable to atmospheric air. The liquid must be allowed to flow as long as possible; but when it ceases, no means should be tried to favour its farther escape. All your attempts would be useless; and were you to employ suction, you might occasion tearing of the lung. When the evacuation is accomplished, what remains to be done? I once thought that iodized injections might be highly useful; but experience has, as regards their use, modified in some measure my opinion. Injections of this kind are never dangerous, nor have I ever seen them followed by any untoward symptom. We need not be frightened, more particularly, with the phenomena of iodic poisoning which sometimes follow their use; which, on the contrary, I consider as a good omen, since they show that the pleura has not undergone too great a change, nor is lined with false membranes, and we may hope that under the influence of this substitutive inflammation, adhesion between the two serous membranes may take place. But are iodized injections really so useful as some persons seem to think? I own that I have great doubts on this subject, excepting perhaps as regards purulent pleurisies.

As to the dressing, that is very simple. Some physicians, especially M. Trousseau, are satisfied with applying over the wound a bit of adhesive plaster cut in the form of a Malteso cross, which I do not think sufficient. In fact, there is reason to fear lest the fluid should continue to drain away, and the wound be converted into a fistulous opening. On the other hand, should we have hydro-pneumothorax, there would be the fear of emphysema, which might soon become general. For this reason I add to the simple dressing of which I have spoken a series of graduated compresses, so disposed as to maintain the sides of the wound in perfect contact, and secure the whole by a body-bandage firmly tightened.

One word more in regard to two accidents, one of which is more frequently mentioned in books than met with in practice—wounding the intercostal artery. For myself, I have not

met with a single example of it; and it seems to me that if you follow correctly the superior margin of the rib, there can be nothing to fear. But may you not wound an internal organ, and penetrate, for example, the liver or spleen? Strictly speaking, this is possible; but what I can say is, that these wounds have generally nothing of a serious character: the possibility, therefore, of an accident of this sort need not beforehand occasion you any uneasiness.

EXTRAORDINARY CASE OF ASCITES AND ANASARCA,

COMPLICATED WITH TUBERCULAR PHTHISIS, CURED BY NATURE.

By JOHN GASON, M.D., A.B., &c.,
Practising Physician at Rome.

In reading an article, in vol. xxx of the 'Half-yearly Abstract of the Medical Sciences,' entitled "Ascites terminating semi-favourably by the formation of Peritoneal Fistula," I was struck with the similarity which it bears to a case which I had under my care in Ireland, nearly twenty years since, of which I now subjoin a statement.

Mrs Mary Ann Farr, æt. twenty-eight years, of the parish of Powerscourt, Co. Wicklow, of a nervo-sanguineous temperament, wife of a carpenter, had, for a considerable time, cough, attended with occasional spitting of blood, expectoration, night perspirations, difficulty of breathing in walking up hills,—and, in fact, the usual class of symptoms and physical signs of pulmonary phthisis, with, however, this rare exception—a large appetite. In addition to the disease of the chest, she had swelling of the extremities and dropsy of the abdomen. She complained also of pain on pressure over the region of the liver. As her disease was advancing rapidly, and her strength diminishing, notwithstanding that she took a large quantity of food—(consuming daily from one to three pounds of meat, in addition to other food) —and as her husband and parents were poor, I proposed that she should go to Dr Steevens's Hospital, in Dublin, where she was put under the care of Dr John Crampton.

There were points of great interest in her case, and she was visited several times by Sir H. Marsh, who was at that time one of the physicians to the hospital, and who coincided in opinion with Dr Crampton, that she was labouring under tubercular phthisis with hydrothorax. Dr Crampton thought that she had also disease of the liver, which, he believed, was the cause of the dropsy, and which had then decidedly declared itself. She appeared to be rapidly declining in strength; her cough was more frequent, her expectoration more copious, the night perspirations more abundant, complete suppression of the menstrual evacuations, and she was daily losing flesh. Her breathing was becoming more oppressed and hurried, the swelling of the abdomen and legs increasing very much; and, in fact, no hope was held out to her parents and husband that she could survive beyond a few weeks at the furthest; and as she expressed a desire to return home, they were permitted to remove her to the country, which they did with much difficulty. A female quack doctor was then sent for, who gave her a decoction of some herbs to drink, and a stimulating liniment to rub three times a day into the legs, the skin of which was now very much distended, shining, and stretched almost to bursting. On being sent for to see her, and finding all her symptoms much aggravated, I punctured the legs in various parts with a fine needle, which gave vent to a considerable quantity of water, and this continued to ooze for several days. The friction of the legs was continued at the same time without my knowledge; which being done carelessly, a portion of the liniment got into the holes made in the legs by the needle. This caused them to inflame, and a portion of the skin equal in size to the palm of the hand sloughed away from the calf of the right leg, and rather a smaller portion from that of the left. This allowed a great quantity of water to flow from the legs,—amounting, I was told, to at least one quart in the day, which was collected by the feet being placed in a vessel. At this time she was unable to lie down, and either sat upright in bed, or was moved to a chair near to the fire.

The breathing was much relieved by this drain from the legs; but the abdominal dropsy rapidly increased, and the umbilicus became very much protruded and distended, giving the appearance of a ring uterine pessary, depressed in the centre, with the circumference very much distended and shining. In about a fortnight after the separation of the sloughs from the legs, I was sent for at an early hour in the morning to go immediately and see this patient, the messenger stating to me that she had burst about five o'clock a.m. On reaching the house, I found the account to be quite true—that the umbilicus had given way, and the whole bed was completely saturated by the fluid which had escaped; and that, in addition, an ordinary-sized stable-bucket had been filled with what had been collected, and the floor beneath the bed was quite wet. The stable-bucket, which had been quite empty, contained at least five gallons and a half of the discharge which had poured through the umbilicus; so that, calculating what was collected, and making due allowance for what escaped, there could not have been less than sixty pints discharged.

She was very faint; but having bandaged her tightly round the abdomen and administered a stimulant, she rallied and expressed herself as much relieved. From this time a considerable amendment took place in her state of health, the cough subsiding, as well as the expectoration diminishing. The night perspirations ceased, and with the exception of another collection forming in the peritoneum, she appeared to be getting well. In three months after this the abdomen was very tense and distended, but not to the same extent as on the former occasion. The umbilicus again gave way, and about half the quantity of water as on the former time escaped from the peritoneum. After this, she mended rapidly: the kidneys took on increased action; the legs, which were still unhealed, began to close, and all her chest symptoms disappeared. In ten years after this, Mrs F. was quite well, strong, and able to go through any amount of physical exertion. She lost all cough and expectoration, regained health and strength, and appeared in every respect perfectly healthy.

(To be continued.)

THE SPIRIT OF THE PERIODICALS.

We extract from the 'Journal of Practical Medicine and Surgery' the following article on *Growing Pains*:

"M. Gendrin agrees with those attentive observers who, at all times, have held that the development of disease is favoured by certain critical periods of human life, such as the first dentition, weaning, the passage from first to second infancy, and the transition from maturity to old age (from 50 to 60). He is of opinion that the integrity of the plastic functions is more or less compromised and impaired at these various epochs of life. In the early stages of existence, this deterioration is the result of the exhaustion induced by the growth of organs hitherto lying in a dormant or incomplete condition; in the later stages, by the natural and progressive diminution of plastic power under the influence of advancing years. M. Gendrin further admits that to each period corresponds a peculiar order of morbid manifestations.

"As an illustration of the foregoing remarks, the Professor adduced the case of a girl, aged sixteen, who had been received into hospital a few days previously, and whose state he considered well worthy of attention. The patient is a delicate, pale, small-sized girl, presenting all the signs of an exhausted constitution. Her mental condition bears the impress of the same debility; she is timid, and, without any adequate motive, suddenly changes from tears to immoderate laughter, and *vice versâ*. This is a phenomenon not unusual during the transition from childhood to puberty, and invariably indicates physical and moral weakness. The frequent outbreak of chorea at this age, in both sexes, and more especially in girls, is also referred by M. Gendrin to the same influence. In M. Gendrin's patient, menstruation is very imperfect; this function was established late, and subsequently was irregular both as to period and quantity: but the symptom which chiefly induced her to apply for admission into hospital was a pain which had settled in the knee without any known cause.

"This arthralgia, said M. Gendrin, is evidently one of those pains so commonly observed during growth, which appear without any tangible cause, and are remarkable for the facility with which they fly for several weeks from one joint to another; they are liable to spontaneous exacerbation, are sometimes attended with swelling, heat, tenderness and some degree of feverishness, and increase on pressure or motion, so as to resemble a rheumatic or scorbutic affection. Walking or standing, however, are in general distressing only, and the patient is not usually confined to his bed. In some few instances, as I have once observed, several joints are simultaneously affected, and fever appears with signs of gastric disturbance or of mild typhus, symptoms which subside in the course of four or five days. The suffering, which at first had been so intense as to elicit screams, decreases, and the disease assumes the form we have described, which it preserves for two or three weeks. This rapid change in the progress of the disease of course precludes the idea of continuous or rheumatic fever; but all doubt on the subject is further removed by the progress of growth, which in some cases has been very rapid, the bones of the limbs having become remarkably elongated.

"This state of things may recur, at variable intervals, during several months, with equal violence, and coincide with considerable growth of the patient. This is due to the simple fact that the morbid condition is but the exaggeration of the efforts of nature to consolidate the union of the extremities of the bones with their shafts, and thus complete their ossification. The turgidity and congestion of the vascular osseous net-work at this stage of their development are such that a very narrow difference here separates the morbid from the physiological condition of these structures. The consequence is occasionally hydarthrosis, and less frequently something more serious, viz., the tumefaction of a condyle, whence may arise deviation of the limb inwards or outwards, inducing a lasting deformity and permanent lameness. Should, moreover, in any particular case a diathesis of any kind be imminent, the circumstances are most favourable to its manifestation; and if a lymphatic predisposition exists, a white swelling may follow, or in another state of the system, mollities ossium and rickets, an obvious indication of insufficient plastic power.

"The treatment of the morbid symptoms induced by growth will therefore consist in allaying or soothing the pains by sedative and gently narcotic applications, in repose in bed, and an appropriate position of the diseased extremities. An emeto-cathartic should be prescribed, with a view to remedy the gastric derangement which occasionally coincides with the feverishness; and as soon after as practicable, the appetite may be solicited by the exhibition of bitter beverages, and the system invigorated by generous diet, combined with the salutary influence of intelligent hygienic directions."

The 'Lancet' opens with reports of the Introductories, in which it has been preceded by the MEDICAL CIRCULAR. Mr. HANCOCK communicates to the 'Lancet' an article *On the Division of the Ciliary Muscle in the Treatment of Glaucoma, as compared with Iridectomy.* In this paper, Mr Hancock reproaches Mr Hulke for his opposition "to my operation of dividing the ciliary muscle," and his favourable opinion of Graefe's operation of iridectomy. We quote the following:

"My first operation for the division of the ciliary muscle was performed on the 9th of September, 1859; and on the 11th of February, 1860, I published an account of the operation, with cases; at the same time stating that I was led to adopt this mode of treatment from the belief 'that the pathological and ophthalmoscopic appearances of the bloodvessels in glaucoma were due mainly to the constriction exercised by the

ciliary muscle;' and that to remove this constriction I operated as follows—'I introduce a Beer's cataract knife at the outer and lower margin of the cornea, where it joins the sclerotica. The point of the knife is pushed obliquely backwards and downwards until the fibres of the sclerotica are divided obliquely for rather more than one-eighth of an inch; by this incision the ciliary muscle is divided.' This is the description of my operation which I published: it does not contain one word about 'striking a knife through the ciliary region towards the axis of the globe,' which is the incorrect version given by Mr Hulke—a proceeding which would be carefully avoided by any one conversant with the anatomy of the eyeball, from the risk of wounding the lens which would inevitably attend it.

"As my operation has now been before the Profession above twelve months, and still continues to be attended with the best results in the hands of my colleagues and myself, I cannot admit that iridectomy *is* the only known remedy for glaucoma. I propose, therefore, to consider, in the first place, the validity of Mr Hulke's objections to my operation, as set forth in the paper already alluded to, and read before the Royal Medical and Chirurgical Society; next, to inquire into the results of the operation of iridectomy, as furnished by Dr Bader's papers in the 'Ophthalmic Hospital Reports' (Nos. 9 and 10); and lastly, to give the results of my own operation up to the present time, with my reasons for submitting it the Profession, not as the '*only* known,' but as the *best* operation for the treatment of glaucoma.

"1. 'The principal points upon which Mr Hulke insists are, 'That the leading features of glaucoma are due to excessive tension of the eyeball, from a superabundance of fluid within it, which distends the vitreous humour; that this fluid (serum) is derived mainly from the choroid; that it might be considered a serous choroiditis.'

"2. 'That the excessive tension of the globe is suggestive of the evacuation of some of the superabundant fluid by tapping.'

"3. That he has 'demonstrated, by microscopical examination, advanced atrophy of this muscle (ciliary) in many glaucomatous eyeballs; whence it follows that the ciliary muscle is not actively concerned in maintaining the glaucomatous process.'

"4. 'To avoid certain alleged disadvantages, paracentesis scleroticæ has been advocated by Middlemore, Desmarres, and Hancock.'

"5. 'That in all probability the success of Mr Hancock's operation is solely due to the drawing away of some of the superabundant fluid. According to this view, it is simply a peculiar mode of paracentesis, and cannot rank as a substitute for 'iridectomy,' until it has been thoroughly established that it permanently relieves excessive intra-ocular pressure,' which, in common with most surgeons, Mr Hulke has found that tapping the vitreous humour fails to do.

"The assertion, 'that the leading features of glaucoma are due to excessive tension of the eyeball from a superabundance of fluid within it,' and that 'excessive tension of the globe is suggestive of the evacuation of some of the superabundant fluid by tapping,' are contradicted and rendered untenable by other portions of Mr Hulke's paper; whilst the results he gives of the operation of iridectomy directly prove that the operation is only of value when the fluid, for the evacuation of which it is performed, is actually not in existence to be evacuated.

"We are told that the reason why iridectomy has failed in the hands of some surgeons 'has proceeded, in many instances, from its having been performed at far too late a period.....that the propriety of operating in the premonitory period cannot be doubted.....that in acute glaucoma, where the operation is done during the first inflammatory attack, or soon afterwards, vision is very completely restored; whilst, in chronic glaucoma, the results are less uniform and less decided.'

"We may hence infer, that three stages of this disease are recognised—the premonitory, the acute, and the chronic—and that the success of the operation is greater the earlier it is performed. It is this great practical fact which seems to me to be fatal to Mr Hulke's theory of glaucoma being due to a superabundance of serum distending the 'vitreous humour,' more especially as that gentleman, in the same paper, describes the vitreous humour as being 'unnaturally firm in this disease;' and that it is only at a late period, when all the component structures are undergoing atrophy, that the vitreous humour becomes fluid, at which time the results of the operation are admitted to be 'less uniform' and 'less decided.' And I am still further supported in the opinion I have expressed here and elsewhere, that fluid is not the cause, but the result, of the disease termed glaucoma, by the following very corroborative paragraph, extracted from Mr Hulke's paper on the 'Pathology and Morbid Anatomy of Glaucoma,' read before the Medico-Chirurgical Society, Dec. 12th, 1857:—'With a view to relieve the tension of the globe, I have seen the sclerotic freely punctured with an extraction knife, after which firm counter-pressure with the finger upon the opposite side of the globe only caused the protrusion of a very small bead of yellowish vitreous humour, such great firmness had it.' Whether the tension of the globe was relieved by the puncture is not stated.

"Nor is it by any means so conclusive as Mr Hulke appears to imagine, that, because he has 'demonstrated advanced atrophy of the ciliary muscle in many glaucomatous eyeballs, this muscle is not concerned in maintaining the glaucomatous condition.' The word 'many' is very indefinite and inconclusive. Mr Hulke does not state in how many instances he has found this muscle atrophied, or what proportion these instances bore to the number of glaucomatous eyeballs which he examined microscopically. He does not inform us whether these glaucomatous eyeballs were obtained after the death of the patient or before, or, if from the former, the time which had elapsed between the death and the examination; for the changes which take place, especially in diseased eyes, are so rapid, that very little reliance can be placed upon such examinations when they have been deferred for any length of time. Neither, where the glaucomatous eyes which he examined had been obtained from living patients, does he tell us the stage of the disease at which they were extirpated, or the circumstances which necessitated their extirpation. It had been but justice that these particulars should have been mentioned before a sweeping pathological statement was unhesitatingly advanced.

"I have already alluded to the three stages of glaucoma mentioned in Mr Hulke's paper—the promonitory, the acute, and the chronic; to his admission that it is only late in the disease that the component structures of the eyeball undergo atrophy; and that whilst iridectomy is most successful during the first two stages, its results are less uniform and decided in the last; whilst Dr Bader states, in his report, 'that the prognosis of chronic glaucoma depends upon the stage in which the eye affected is operated upon: when blind for some time, it is not expected to regain sight; a chronic glaucomatous eye, with mere perception of light, is rarely improved by operation.'

"Mr Hulke's microscopical examinations, therefore, cannot be admitted as at all conclusive or of much value against my proposition, 'that the ciliary muscle exercises considerable influence in maintaining and aggravating the glaucomatous condition,' and still less against my operation for the division of this muscle. They only prove that in certain cases of advanced glaucoma, in which an operation is admitted to be rarely successful, the ciliary muscle may have undergone atrophy with the rest of the tissues; but they by no means prove that this is the case in all or even in average instances, as we cannot for one moment imagine that any surgeon would extirpate a glaucomatous eye capable of relief by operation, unless under very peculiar circumstances. I presume it is only recently that Mr Hulke has discovered this condition of advanced atrophy of the ciliary muscle in glaucomatous eyeballs; otherwise he would scarcely have omitted all mention of a fact of so much importance in his paper upon the 'Pathology and Morbid Anatomy of Glaucoma,' read before the Royal Medico-Chirurgical Society in December, 1857.

"On the other hand, my friend and colleague, Mr Hogg, has kindly furnished me with the particulars of two glaucomatous eyeballs, extirpated at an advanced period of the disease, in which his microscopical examination demonstrated the ciliary muscle as highly developed, and anything but in a state of atrophy. I do not, however, advance these cases as of themselves sufficient to controvert Mr Hulke's assertion—their number is too small; but, at the same time, they afford pretty conclusive proof that the ciliary muscle is not atrophied in all cases even of advanced chronic glaucoma. Neither can I admit that the success of my operation in any way depends upon, much less is solely due to, the drawing away of some of the superabundant fluid; or that it is a peculiar mode of paracentesis, to be classed with the operations of 'paracentesis scleroticæ' of Middlemore and Desmarres.

"I think I have succeeded in showing that, according to Mr Hulke's own statements, there is no superabundance of fluid in those cases most likely to be benefited by the operation; therefore the drawing-away theory falls to the ground, and is still further negatived by cases Nos. 15 and 16, appended to this paper.

"The object of applying the term paracentesis scleroticæ to my operation, and classing it with the procedures of Middlemore and Desmarres, is transparent enough. Paracentesis of the cornea and sclerotica, as practised by these two surgeons, has not met with any great amount of success. If, therefore, the Profession could be impressed with the notion that my operation was nothing more than one or the other of these proceedings, and that any transient good which it might be the means of effecting was due to the mere evacuation and draining away of fluid, it would be looked upon as deficient both in value and originality, and would, as a matter of course, fall into disrepute, and proportionately give greater prominence to the operation—iridectomy. It is true that the word paracentesis means, literally, a 'piercing through;' but its application in surgery has hitherto been restricted to the operation of tapping. If we were to attempt to describe the operation of tenotomy in club-foot as 'a peculiar mode of paracentesis' of the leg, or of the foot, or if we were to designate the operation for the extraction of hard cataract as 'a peculiar mode of paracentesis' of the cornea, we should expose ourselves to the charge of pedantry; yet the name may with equal propriety be applied to these operations, or even to iridectomy itself, as to my operation for the division of the ciliary muscle. Hence the term as applied to this operation by Mr Hulke is a misnomer.

"The operations of Middlemore and Desmarres were introduced for the avowed purpose of relieving intra-ocular tension by the evacuation of fluid. My operation, on the contrary, is introduced for the avowed purpose of relieving the constriction of the several coats of the eye by division of the ciliary muscle.

"An increased quantity of fluid may or may not be present, and, when present, some may flow by the side of the knife; but this is merely a coincidence, not by any means the primary object of the operation; for mere evacuation of fluid without division of this muscle is quite incapable of affording permanent benefit.

"In my former paper I pointed out the variety of opinions entertained by the supporters of iridectomy in this country as to the *modus operandi* of the operation. I would here venture to suggest another. I believe it will be found in the course of time, that the element of success is the same in iridectomy as in my operation—viz., 'the division of the ciliary muscle;' that, from the situation in which Von Graefe makes his first incision, he at the same time cuts it through, and I have very little doubt it will ultimately be found that the extent of this incision may be advantageously curtailed, and the tearing away of the iris altogether dispensed with."

The 'Medical Times and Gazette' contains a continuation of M. CLAUDE BERNARD'S Lectures on *Experimental Pathology*, the special subject being the pancreatic secretion. He says:

"We have informed you that in most animals the pancreas is double in the embryonic state, and that the two separate portions of the glands coalesce after birth, the existence of a double pancreatic duct in man and the higher animals being a vestige of the former state. We have, in fact, ascertained the existence of a double pancreas in the canine fœtus, and in the embryos of several other animals. In birds, the pancreas is usually double: the pigeon possesses two pancreatic glands, one on each side of the mesentery, within

the arch of the duodenum; a similar disposition exists in the buzzard and other birds of prey, and in several domestic birds. In reptiles there also exist two glands, each of them provided with its own excretory duct. In man and the higher animals, the two divisions of the pancreas being united into one, the two ducts are usually anastomosed, except in a few particular cases.

"It now remains for us to examine whether (as various authors have supposed) there exist, beside the principal glands, certain accessory organs intended to fulfil the same purpose. In other words, does a secondary pancreas exist? Aselli answers the question in the affirmative; but the organ which he mistook for a gland is in reality a mere agglomeration of abdominal lymphatic ganglia, which constantly exists in the dog and a few other animals, but it is not found in man. The microscope amply demonstrates that this little body is not endowed with a glandular structure.

"It has been supposed that the small glandular bodies disseminated in the mucous coat of the duodenum enjoyed the same properties as the pancreatic apparatus; such was the opinion of Brunner, who gave his name to this little gland. In this case, as we previously observed with respect to the salivary apparatus, the analogy of structure which exists between them created a false notion among anatomists, for the secretion of these minute organs is essentially different from pancreatic juice. In order to prove his assertion, Brunner had recourse to the following experiment:—He endeavoured to destroy the pancreas, in the hope of producing a consecutive enlargement of the duodenal gland; for it is a well-known fact, that in all cases where double glands exist, the extirpation of one of them gives rise to a corresponding hypertrophy of the other; one kidney being removed, the other grows larger; the same is the case with the testicles. Brunner therefore supposed that, after destroying the pancreas, the accessory glands would increase in size; but he was never able, in his experiments, to extirpate the whole of this apparatus: nothing, in fact, is more difficult than to remove in a living animal that portion of the pancreas which lies behind the stomach, in the immediate vicinity of the cæliac arteries, the slightest injury to which would instantly provoke a mortal hæmorrhage; and Brunner himself, in making the autopsy of the animals on which the operation had been performed, was enabled to ascertain that he had only destroyed a small portion of the gland, that which lies immediately behind the intestinal tube. The problem has not, therefore, been solved by this observer, who was never able to realise the proper conditions of the experiment; but a different method has enabled modern physiology to ascertain that these glands are essentially different. Let a portion of the mucous lining of the duodenum be removed, and allowed to macerate during a certain space of time in tepid water; a ropy, viscid, and semi-opaque fluid is obtained, which highly resembles water impregnated with saliva. Now the tissue of the pancreatic gland, after macerating in water for a certain time, produces a totally different liquid; it may therefore be confidently asserted, that far from resembling the pancreatic apparatus, these little glands play an entirely distinct part in the digestive process.

"Let us now examine the physical and chemical properties of the pancreatic secretion. The rabbit now placed before you has lately undergone the operation described in the preceding lecture; the tube which has been inserted into the fistulous aperture provides us with an abundant supply of this fluid, for the rabbit being (as I have already observed) one of those animals the stomach of which is never empty, the interruptions which take place in the digestive act scarcely diminish the flow of this secretion, as in the case of other species; besides, in herbivorous animals the amount of pancreatic juice which we are enabled to collect is much larger than in the carnivora; the latter usually make a single meal in the twenty-four hours, while the former are constantly occupied in feeding during the whole day. In dogs, for example, it is only at intervals that we can secure this fluid, immediately after the animal's daily repast.

"The pancreatic juice which I have just drawn from the duct of this rabbit is limpid, viscous, colourless, flowing, as you observe, in large drops; it has no particular odour, and its taste is slightly saline; on being tested in the usual manner it gives a strong alkaline reaction. The application of heat and the addition of acids quickly produce coagulation; on holding the tube which contains it over the flame of a spirit-lamp for a few seconds, it coalesces into a solid mass; and on pouring a few drops of nitric acid into another portion of the same fluid, a similar result will equally be obtained. The pancreatic secretion, therefore, presents, as you perceive, all the characteristics of an albuminous fluid, and the presence of albumen is probably the cause of its peculiar viscosity.

"(M. Bernard repeats these various experiments before the class): he then proceeds to say:—

"In making experiments on the pancreatic body, it is necessary to keep in mind a remark which equally applies to similar operations on other glands. While the organ is in a period of rest, the ducts remain filled with the produce of its secretion, and viscous liquids, flowing as they do with greater difficulty, are more liable than others to remain stationary, when the *vis a tergo* has ceased to act, the functions of the gland being momentarily suspended. If, therefore, you compress the duct, you will cause the fluid therein contained to escape by the tube attached to it, without any secretory act having taken place. In this manner the physiologist may be frequently led into egregious errors, if proper care has not been taken to empty the ducts before commencing an experiment. Suppose, for instance, that it is desired to know whether the section of certain nerves leading to the gland brings about the immediate cessation of its activity, or whether galvanic excitation applied to a given branch renews the physiological act; the mere fact of the ducts being full might entirely mislead the observer; the galvanisation of the nerve, or an accidental pressure exerted on the gland, may cause a small quantity of liquid to escape from the tube, which would probably be attributed to fresh secretion, although it would in this case be simply that which remained in the duct before the commencement of the operation.

"In his experiments on the pancreatic juice, De Graaf usually found its action acid; but the method employed by this observer being, as I stated before, very imperfect, the liquid which he obtained probably did not enjoy its normal properties. It is strange, however, that Tiedemann and Gmelin, who obtained it by the same experimental process as myself, should also have found it acid in the majority of cases; you see that we have had a decided alkaline reaction in testing the fluid taken from the animal now placed before you, nor have I ever found it acid in any of my experiments. It is difficult to account for the error committed by these eminent physiologists, which, in my opinion, must have been the result of accident.

"It is interesting to ascertain, with respect to the pancreatic secretion, what are the substances which make their appearance in this fluid after being injected into the veins, and what, on the contrary, the bodies which do not appear capable of passing into the secretion. As a general rule, all the substances which pass off by the pancreas are likewise eliminated by the salivary glands, while those which are not accepted by the former apparatus are equally rejected by the latter; thus, chlorate of potash, iodine, and its various compounds, pass off equally by both of them, while the prussiate of iron, which, when injected into the torrent of the circulation, escapes from the system by the kidneys, does not make its appearance either in the saliva or in the pancreatic juice. But although in this respect the salivary and pancreatic secretions resemble each other, they differ widely in many important points. The production of saliva takes place by intermissions, so to speak; it flows when the jaws are set in motion, and ceases as soon as the act of mastication is ended: the pancreatic secretion, on the contrary, flows without interruption during the continuance of the digestive process. Another peculiarity connected with this secretion, which does not occur in the case of the salivary gland, is the alteration which takes place in its properties while it is being produced. During the first stage of digestion it is a distinctly viscous and adhesive fluid, but as the process advances its character changes; it becomes watery, and at the same time more abundant, while its coagulability becomes proportionately diminished. This singular phenomenon is invariably observed, and the same fact has been noticed with reference to various other secretions; such, for example, is the case with the mammary glands; the first drops of milk drawn by the child contain a much larger proportion of solid constituents than the succeeding portions of the lacteal secretion, though the abundance of the fluid produced sensibly increases.

"The pancreas being endowed with very great sensibility, the selection of animals for the purpose of collecting the produce of this gland is not a matter of indifference: the subjects of such experiments should be taken from that class which exhibits the greatest endurance under pain, and supports operations of this nature with the least inconvenience. A shepherd's dog, in other words, is preferable to a pointer, setter, greyhound, or any of those which belong to the more delicate breeds; the operation in the case of these latter animals disturbs the system to such an extent, that the digestive process is suddenly arrested, and, as a consequence, the secretion of pancreatic juice stops also; or, if it should continue, it is no longer the normal fluid, the properties of which have just been described. When, on the contrary, the operation has been performed on a more vigorous animal, we find that as long as the stomach remains empty, no secretion whatever takes place; the pancreas is in a state of absolute rest; but no sooner does digestion commence, than the liquid begins to flow in drops from the extremity of the tube inserted into the pancreatic duct: in the first instance it is thick and viscid, but as the process continues, it increases in quantity, and becomes of an aqueous description.

"We shall now repeat the experiment before you, gentlemen, and you will be enabled to ascertain for yourselves all the various facts to which we have just drawn your attention. The animal which is about to undergo the operation has just partaken of food.

"(A large shepherd's dog being now brought into the amphitheatre, M. Bernard performed the operation according to the method previously described. The duodenum and pancreas being simultaneously drawn out through the wound, the latter organ was found to be unusually red and vascular; a proof that the activity of the gland coincides with the digestive process. The duct having been singled out with great precaution, it was opened with a pair of fine scissors; a large silver tube was inserted at once, and fixed by means of a ligature; the abdominal walls were then carefully brought together by means of a suture, and, in order to collect the fluid secreted, a small reservoir of india-rubber was fastened to the extremity of the tube: at this moment several drops of pancreatic juice escaped from its orifice.)

"We shall examine, gentlemen, the liquid obtained from this animal at our next meeting; and a large amount of pancreatic juice being thus placed at our disposal, it will be easy for us to demonstrate its principal properties."

We find in the 'Medical Times and Gazette' a continuation of Dr CONOLLY'S *Recollections of the Varieties of Insanity*. We extract certain portions of the paper, both for the excellent advice it offers, and its singular recitals of disturbed states of mind among lunatics:

"The officers residing in Asylums for the Insane soon learn that they live surrounded by a very observant crowd; and that their manner, their appearance, their attentive or their indifferent habits when they visit the wards, and even their dress, are all critically noticed by the patients. It is important not to forget this, which even the Medical officers may sometimes do. Other visitors often give great offence without intending to do so, exhibiting mere curiosity, or the same kind of surprise and fear that they would feel among wild animals, and passing by the patients without regard to the words addressed to them. Even members of committees sometimes greatly err; opening and shutting the doors noisily, and regarding everybody and everything with the air of masters; unconscious of the unfavourable feelings they excite. Deriving a peculiar pleasure from conversing with the patients at Hanwell, whose real feelings it was so much my interest to understand on assuming the task of regulating the lives of so many of them, I became so fully acquainted with these among other peculiarities in such communities as to be impressed with the

necessity of being as precisely attentive to the demeanour expected by them as if I resided in a court. The subject is significant enough to merit the attention of all who live among the insane, and who wish to possess habitual influence over them. To all in such a position the duty of the wards is the most serious duty of the day, and should be preceded by no ordinary business, nor by any business productive of excitement, or anxiety, or irritation, or, if possible, of sorrow. The impress of these affairs will be detected in the physiognomy of the watchful men and women in the galleries, waiting for the morning salutation, and for daily directions, various and minute, but all of importance to the inhabitants of an asylum, and influencing their lives from day to day.

"Experience will teach an intelligent officer all this, and much more, if he is duly impressed with the real object as well as the probable effects of his intercourse with the patients. A kind of military inspection, and too precise an attention to minutiæ which merely please the eye of visitors, and do not enlarge the comfort of the troubled inmates, is in such a situation quite out of place. Whatever concerns the bodily and mental health should solely occupy the attention. The cleanliness, the clothing, the ventilation, the food, and all direct and indirect means of tranquillising the feelings, and composing and regulating the mind, are all subservient to both indications. While ever mindful of these things, an even and unexciting manner is so valuable, that, if not naturally possessed, it is highly worth cultivating. Sternness, severity, and the old boasted method of governing lunatics by the eye, do not belong to the system of modern days. They were the characteristics of ignorant superintendents and vain physicians in a more careless age; yet calmness of deportment should be at all times maintained, as remote from mirth, and joking, and ridicule, as from coldness and unkindness. It is among the peculiarities of the insane to construe eccentricities in sane persons into proofs of a malady akin to their own; and care should be taken that neither the dress nor the behaviour of those passing through the wards give support to this reading. All my observations in this part of these papers refer chiefly to large asylums; and the minute attentions to dress and appearance are at least as important among pauper lunatics as among those of higher rank. It may even be said that they are more important, the commoner class of people, sane or insane, being most apt to draw unfavourable conclusions from the eccentric costume of those in a higher rank of life than themselves. The Medical officers are often exceedingly embarrassed by the thoughtlessness of holiday visitors, who come down to see one of the wonderful things of the day, with no more serious thought than that the details of their morning may amuse those who take no deeper interest in such a spectacle than they do. Many visitors simply regard it as merely a disagreeable exhibition which they think ought to be seen once in a man's life. Very amiable ladies often accompany visitors of this sort, and regard the patients with blank astonishment, until alarmed by some appearance of indignation in those they gaze upon with eye-glasses as they would on the details of a flower-show. There are also learned visitors, from various countries, who come to teach rather than to learn; and who direct a long metaphysical discourse to the Medical officer, not employing the observation which should precede all such speculations, and could alone give them value. Nothing of this kind escapes the observation of the patients; they resent mere curiosity, deride affectation, and simply look upon philosophical declaimers as strange people, whom their friendly doctor is quietly conducting to appropriate wards. But all these things counteract the good effect of the morning visit. It is even more important to remember that patients are singularly skilful in discriminating between true and feigned sympathy; between the tone and manner which expresses sincere interest respecting them, and that which only reveals to them a simulated benevolence, provocative of their disdain.

"In all intercourse with insane persons, fidelity, sincerity, and truth are indispensable. In this department of Medicine, consequently, the range of mere quackery is happily limited; the course of the malady is too powerful for the display of deceptious promises. The physical causes may be obscure enough to give scope to audacious assertions; but the events of the malady follow too quickly, and are too intelligible, to give countenance to long-continued attempts to deceive the relatives of patients with fallacious hopes. It is in the daily intercourse with the insane themselves that truth is especially to be recommended. Friends and relations are too much disposed to think that in such intercourse a large extent of deception is unavoidable, and that every species of falsehood is allowable. They deceive themselves alone. False explanations are given to the patients, false names of persons and places invented, and the cleverness with which this is supposed to be done is very complacently reflected upon; but the patient, the object of this dissimulation, usually suspects from the first that he is played upon and mocked, and generally discovers it after a little while; from which time all hold upon his confidence is lost. It is quite practicable to treat the patient with candour, and yet to evade imprudent communications. Hope may be kept alive without the aid of deception; and the patient may be made to comprehend the desirableness of temporary retreat from social excitements without being humiliated with any stronger definition of his existing mental incapacity. If a patient is assured that what is said to him is true, he will seldom take offence on being told that there are subjects on which it is thought best, for a time, to say nothing at all. In general, the best rule to be observed in discoursing with the insane is to accost them, listen to them, and reply to them, as if they were perfectly in their senses, so as not to excite in their minds any suspicion that they are degraded, or even to confirm their own suspicions, generally existing, although often concealed, that they are not quite in their reasonable mind. This rule, also, is applicable not only to patients of education and station, but to the poorest. The malady which has confused their thoughts has very often quickened their perceptions, and made them uncommonly sensitive as to the manner in which they are addressed.

"In the course of the physician's daily walk through his wards, he is appealed to by those who are discontented, and whom often a few words will soothe; by those who are angry, and who should be calmed, if possible, before he leaves them; and by many who have petitions of various kinds to prefer to him. Some of their demands cannot possibly be granted, but this may be so stated as not to give offence; the greater part are of things trifling in themselves, yet very important in the monotonous wards, and these should generally be granted, and complied with immediately, or with as little delay as possible. These requests are, indeed, usually, for an interview with their relatives; for some change of diet or in dress; for books, for newspapers, for writing materials; all of which are really so many little aids to amendment, and, judiciously granted, strengthen the bonds of confidence betwixt the patients and the doctor. Demands for immediate liberation are more common among patients of a higher rank; and even these may be evaded without great difficulty.

"A great number of insane persons have an almost insatiable desire to write letters. They begin at the top of large sheets of paper, and cross and recross the lines, as if never satisfied that they have sufficiently explained themselves. The outside of their letters generally corresponds with the oddity of the interior, so that a lunatic's letter is usually recognised at once. Some patients write the same letter again and again, alike in expression and in subject, and this perhaps every week. Others write a short note, commonly some peremptory order, every day, and present it to the physician in silence, but with an air of importance; these decrees are often addressed to the matron, or the steward, or the cook, to be transmitted to them with his authority. Letters to the Lord Chancellor are very frequent; other great personages, except the highest in the land, being comparatively little regarded. These productions of insane minds, although the expression of deranged thoughts, are not to be disregarded by the physician who wishes to know the feelings and desires of those severed by their mental state from the busy world. The secret impulses of patients may often be learned from them; the remains of reason are in many instances best estimated by a consideration of their contents; and the surviving affections, the tender recollections, the anxiety about children, and the attachment to wives or husbands, will many times be found written with such simple eloquence, that the perusal of a poor patient's letter will much increase the interest felt in his welfare, and even reanimate in the mind of the physician himself the hope, which so often falters, that the patient is not beyond recovery, and that his restoration to those he still remembers and loves may yet be possible."

Again:—

"There were letter-writers among the patients at Hanwell, of superior attainments, and whose opportunities of mental cultivation had been more extensive; skilful mechanics, whose thoughts had received training in Mechanics' Institutes, and whose improvement had been aided by the publications of the Society for the Diffusion of Useful Knowledge. When the active minds of such men became deranged, the confusion was even more complete. One patient of this description was long an object of my observation. On his admission, he lamented that he had not been able to obtain an interview with Lord Brougham, and complained of the infringement of his liberty as a subject, by being followed in the streets by the police-officers, with a thought-taking instrument, of which the basest advantages were taken. This patient passed no considerable portion of his time in inscribing his ideas in pencil on the stone stairs, whole flights of which became covered with writings that nobody took the pains to decipher. But his moods were variable, and his compositions on paper were sometimes sententious and even pompous, sometimes curiously incoherent, and sometimes excessively irate. One morning he deposited with me the following document, as if by doing so every difficult social problem was settled:—

"'The most powerful of all our decrees is to know all we can with respect to our rights and liberties as men. And all the most profound desire of our most nocturnal decree, is the most powerful of all the rights of our ancestors. And the way to obtain all the most powerful of our aid, and all the most profound aid of those that are most able, and capable to do those things. The most Powerful of all our wants are the all wise decree'ers of our most important decision: of all the lost importance of our most decided importunate Proprietor, to refund all that's proper. Amen.'

"Without attempting to unravel the shreds and fragments of thoughts in this writing, I proceed to give another composition of the same author, prompted by an imaginary event calling for more definite expression; it was addressed to His Royal Highness the Duke of Cambridge, per Lord Brougham and Vaux:—

"'I write to acquaint your Royal Highness of the murder of the Duke of S—— by an instrument of the fourth division of the Government Electrical Telegraphs described in part in 'Chambers's Edinburgh Journal' of September last. I am prepared to attend a Coroner's Inquest when the Royal Family may desire. I am a person stolen, November, 1841, by the agents of the St Pancras Poor-law Directors, formerly a Lecturer on Chemistry and Machinery, and Hon. Secretary to the —— Literary and Scientific Institution and Practical Knowledge Society. I have been confined twelve months of the time in St Luke's Hospital, Old street, by a conspiracy of Sir ———— and the Directors of the above Asylum. 'B. L. J.'

"This patient's general behaviour was so composed that but for the help afforded by his letters, the variable states of his mind, and even his peculiar mental malady, would almost have escaped observation; but his written compositions afforded proof that even in a state of chronic incoherence there are accessions and intermissions of mental disturbance not uninteresting to the student of mental peculiarities. The following portions of one of his letters curiously illustrate incoherence in its highest degree:—

"'Hanwell Middlesex Natural History Company Machine Station of Galvanic Magnetic Electro Magnetic Electric V.P. of Herald's College, City of London, Great Britain. To the Right Honourable Miss —— President Lady of the Evidence of the Precedents of the Queen Regnant Rufus the ancestry of the female line of the House of Guelph. Agreeable to the wish of Lord Brougham and friends of Staffordshire I

have allowed my body and property to resolve under Mesmerism into the desired positions the wisdom of the late Duke of Sussex and Privy Council friends Freemasons and Odd Fellows. The establishing of a House of Lords and Queen Regnant Rufus and Consort, Duke Stuart precedents will be due under the Duke of Richmond Prime Minister. I have the honour to hand the title of Arch Bishop of Surrey as your lordship's duty Deputy Chancellor of Exchequer of ancestries Ministries of the Patrol with Erard and friends respects.'

"Such a singular mixture of ideas, political, scientific, and archæological, with the closing infusion of some musical recollections, would scarcely be worth referring to, but for the opportunity afforded in this case of impressing on the minds of young Medical Officers of Asylums the useful truth, that even patients thus occupied and bewildered are observant of the manner of those who address them; and that as they are conciliated by kindness, they may be exasperated by any appearance of slight or neglect: for this tranquil dreamer, who was fond of music, fancying he was mocked by the humane and excellent Steward of the Asylum, who had unfortunately forgotten some promises of procuring certain musical publications, was roused for a time from mere chronic incoherence into mania, under which the character of his epistolary correspondence underwent a remarkable change; his ideas becoming very distinct, and his anger very extreme. A portion of one letter written in this temporary frenzy is not unworthy of perusal. The letter was addressed to myself, as the general referee at that time in cases of dissatisfaction.

"'Dear Sir,—Mr —— is an eminent rascal. He is a compound of regue, fool, and coward, instinct with malignity. Some time since, I wrote a letter to you respecting some music which this scoundrel had received orders from the Committee to procure for us, which, out of spite to me, he had neglected to do, ever protesting that he would get it to-morrow, and ever violating his promise, which he never intended to keep. I wish to confront this knave before the Committee, for the purpose of denouncing his small rogueries, exhibiting him to them in all his glory of malignity and petty larceny. He is a Methodist, a rogue, a fool, and a coward. Stupid dastard villainy is as essential a part of Wesleyan Methodism, as is murder of Thuggee. May he be d——d above the earth, may he be d——d beneath the earth,' &c., &c.

"Two things are, at least, worthy of note in this letter. The excitement of anger seems to have corrected the writer's ordinary incoherence; and the anger, occasioned by the apparent neglect of a promise made to him, is so excessive that he almost exhausts the language of vituperation under its influence. The first is a fact that may be studied with some advantage; and the second is one that an officer of an asylum cannot forget without detriment to the tranquillity of those under his charge, and a considerable loss of his power to do good to them."

Dr Robert Lee contributes to the same journal his Reports on *Clinical Midwifery*. We extract some cases:

"*Case* 644.—At six p.m. on January 10, 1853, I was requested to see Mrs M——, who was in the eighth month of her fourth or fifth pregnancy. She had recently been suffering severely from catarrh, caught by exposure to cold during a long railway journey. The pulse was rapid and feeble; she looked pale and exhausted, and complained of great faintness. The upper part of the abdomen had suddenly become large, hard, and tender; her situation, she said, was different from what it had been in any former pregnancy, and expressed her conviction that she was dying. The pains of labour had not commenced, and there was no discharge of blood from the uterus, and the orifice was not open. Some warm wine-and-water was given, but this was soon rejected by vomiting. In a little while she felt better, and fell asleep. I remained in the house and saw her from time to time, fearing that internal uterine hæmorrhage had taken place. At half-past nine p.m., on making an internal examination, the os uteri was felt high up and closed, and I did not see how any interference could be beneficial. In half an hour she complained of pain, and said the liquor amnii was escaping. I examined, and the finger was tinged with blood. The membranes were immediately ruptured with the finger, and a great quantity of water escaped. Labour pains soon followed, and at eleven o'clock a dead child was expelled. The binder had been firmly applied as soon as the pains commenced. The placenta immediately followed the child, and a great coagulum of dark-coloured blood, and a large quantity in a fluid state. Pressure, stimulants, and cold were employed vigorously; the uterus contracted, and the flooding ceased. But symptoms of fatal sinking were soon observed, and she died at two o'clock in the morning.

"*Case* 645.—On January 12, 1853, at two a.m., the late Mr James Hunter, of Islington, requested me to see Mrs B——, who had been upwards of thirty hours in labour. She was the mother of a large family, and all her previous labours had been natural. The vagina and posterior lip of the os uteri were very greatly swollen, and in a peculiar œdematous manner. The head had not descended into the cavity of the pelvis. We waited six hours, but there was no progress, and there being much sickness and vomiting, with exhaustion, and no hope of the head passing, we resolved to have recourse to the perforator and crotchet. Great and long-continued efforts were required to draw the head into the cavity of the pelvis. The cause of the obstruction was not ascertained until four years after. The patient recovered in the most favourable manner.

"*Case* 646.—Mrs B——, December, 1857: Since her confinement, on January 12, 1853, in the manner now related, she has been regular at the monthly periods until three or four months ago. Since then nothing has appeared. There is now a great enlargement of the abdomen, which does not arise from the gravid uterus. The os uteri is felt close to the symphysis pubis, and a large hard mass behind the uterus. The abdomen is much larger than it ought to be at the end of the fourth month of pregnancy. She is not certain if she felt any enlargement of the abdomen before the disappearance of the catamenia. The enlargement has increased rapidly during the last three months. There is frequent desire to pass the urine, and the bowels do not retain their contents in the usual way. No swelling of the feet. On January 10 the movements of the child were felt, and she complained that there was something unnatural about the abdomen. On Monday, March 22, 1858, when about six months pregnant, labour came on spontaneously, the membranes having burst on the Friday before. Dr Allen examined and could feel no part of the child. I was desired to go and see the patient. I felt the whole hollow of the sacrum filled up with a large soft irregular mass, apparently connected with the posterior part of the body and neck of the uterus. The os was high up. With difficulty I reached the os, and felt the funis without pulsation. My whole hand was then introduced into the vagina, and my fingers came in contact with a foot, which I seized with great difficulty, and drew down, and had secured with a tape. By slow firm traction, the breech and other lower extremity were brought down. Great difficulty was experienced in extracting the head after the trunk. I got my finger into the mouth, but it would not come down. Dr Allen then passed up his right hand, and got his fingers round the back part of the neck, and by pressing up the tumour with the left index-finger, and at the same time drawing down the trunk, the os was brought into the axis of the brim, and the head gradually escaped.

"*Case* 647.—Mrs B——, being again in the fifth or sixth month of pregnancy, with Dr Allen I perforated the membranes in the afternoon, with the stiletted catheter, (about three o'clock,) and the liquor amnii immediately began to escape, but pain did not follow, 'notwithstanding she had taken a large quantity of ergot of rye previous to the operation; but during the evening,' says Dr Allen, who had the care of the patient, 'this gradually crept on, and the fœtus was expelled at 5.15 on the morning of the 14th, after several hours of severe suffering. On this occasion the head presented, and having the same condition of parts to contend with, I got the right index-finger into the os, at the same time using pressure on the tumour, as in the former case.' She is now in the enjoyment of good health."

"*Case* 649.—Mrs S——, aged 44, February 16, 1853. Has had sixteen children. In the last confinement was attended by Mr ——, and the forceps was applied when the labour had not continued more than seven hours, and the pains continued regular. The eye of the child was injured. The perineum has been torn down to the rectum, but the rectum is not injured. Its contents are, however, sometimes involuntarily expelled, which causes great inconvenience and distress. This patient reported that the Practitioner, by whom she had been attended on this occasion in the country always carried the forceps with him. All her previous confinements had been natural.

"*Case* 650.—On April 4, 1853, Mr Phillips requested me to see a case of profuse uterine hæmorrhage from complete placental presentation. The os uteri was so rigid that he could not succeed in passing the hand into the uterus to turn the child, though he employed caution, and for a considerable period all the force that he considered justifiable. The hæmorrhage continuing profusely, and there being great faintness, he requested me to attempt to deliver. I passed the whole hand readily into the vagina, and then the fore and middle fingers through the os uteri between the placenta and uterus, pushed aside the head, came in contact with an upper extremity, pushed this aside also, and then got hold of a lower extremity, and in a very short time extracted the child alive. Mr Phillips expressed great astonishment on the occasion, not having heard before, or remembered, that the operation had often, under similar circumstances, been performed by the same means. The result of the case was most satisfactory in all respects. What would the result have been had the placenta been torn away, and the child left to take care of itself?"

"*Case* 652.—Some time after this, I was called to see a poor woman, who lived several miles from London, who had distortion of the pelvis, and in whom, during labour, the head had been separated from the trunk, and left within the uterus. The midwifery forceps had been employed, and all other means that could be thought of, to extract the head, but without success. When I saw the patient, the greater part of the day had been spent by different practitioners in fruitless attempts to deliver the head, and the patient was greatly exhausted. I introduced my left hand with difficulty, completely within the uterus, which was contracted, and got my fingers round the head, so as to fix it in some degree. I then introduced the crotchet, and getting the point over the fore part of the cranium, exerted all the force that was in my power to tear up the bones freely, and allow the brain to escape. With the hand and the crotchet, the head—after great efforts, continued until my strength was almost completely exhausted—was brought out of the uterus and pelvis. The patient recovered, and about twelve months afterwards I saw her, with the vagina completely closed up, in consequence of sloughing, and I have never since heard anything of the case.

"*Case* 653.—On July 19, 1853, the late Dr Yell called me to see a case of inverted uterus, in Orange street, Leicester square. I was informed that it was the first child, that the labour was protracted, and that the cord had surrounded the neck, and was very short. The placenta immediately followed the child, and soon after a great flooding took place. Whether the midwife who had attended the patient had made strong traction on the cord was not ascertained. The attempts to reinvert the uterus which were made were unsuccessful. This patient was alive some years after the accident."

"*Case* 655.—On July 22, 1853, I was called to Mrs B——, who had been delivered two hours before of a living child by a midwife who had long been in practice. Immediately after the birth of the child, an immense rush of blood took place. The placenta was soon removed. I found the patient in a state of insensibility, the jaws clenched, and the power of swallowing entirely lost. A tablespoonful of brandy only had been given. There was a binder, but loosely applied. The patient had been suffering from distressing symptoms about the chest, especially difficulty of breathing, and sense of fulness amounting to suffocation some time before her confinement, but the pulse was so feeble that it was not considered proper to take blood from the arm or to apply leeches.

(Continued at page 244)

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

THE MEDICAL CIRCULAR.

WEDNESDAY, OCTOBER 10, 1860.

THE INTRODUCTORIES.

Our Medical firmament has been particularly resplendent during the past week. Astronomers tell us that in the month of November there is a periodical shower of falling stars, which give a peculiar interest to that period of the year: so, in the month of October, we Doctors are delighted with a similar phenomenon, and eagerly watch the display of an unusual number of rising meteors that shoot and coruscate in our scientific empyrean. Let us see if we cannot bring a Rosse's telescope to bear upon these shining lights, with the purpose of estimating their altitude,—or perhaps their density. Each of them revolves around a common centre—Truth; some of them describing a tremendous parabola, and travelling, comet-like, with an eccentric gyration far away into the regions of undistinguishable darkness; others observing, with becoming gravity, a respectable conformity to well-understood laws,—some near to the sun, others far on the outer verge of his orbital attraction—a few very brilliant, but obviously barren: and, on the other hand, there be some that shine with a temperate, modest light, but exhibit, nevertheless, ample evidence of fertility and culture. Let us not run our simile to death, but come at once to the subject of our article.

Our readers have, no doubt, perused the Introductories, and formed their own opinion upon their several merits. As opinions differ, however, there can be no harm in our adverting to a few of their salient points. We may remark that three or four of these addresses are characterised by great ability, as displayed either in the thought or the composition: we may instance particularly those by Mr Grainger, Mr Savory, Dr Wilks, and Dr Barnes. On the whole, perhaps, Mr Grainger's is most remarkable for its boldness of view, aptness of statement and illustration, and philosophic tone. This gentleman has spoken his last word on topics that have had the consideration of his entire thinking life, and the solemnity with which he announced his doctrines evinces the strength of his convictions. The substance of Mr Grainger's address might be summed up in these three words: What is life? How does Mr Grainger answer this question? He says:

"I must beg you plainly to understand that what I am about to submit to your judgment has reference solely to the phenomena of the mere organic and animal life, to the actions of the body alone—to that life which man shares in common with a cabbage and a worm; that it has no relation whatever to the conscious existence, and still less to the spiritual—to the soul—which, as we are taught by the word of God, and only in a less degree by the researches of all science rightly interpreted, is an entity perfect in itself, and distinct from that earthly tabernacle in which it is now imprisoned; that, in fine, the body is formed out of the ground, into which the Lord God breathed the breath of life, when man became a living soul. With this all-essential restriction, I conceive it may be assumed, in strict keeping with inductive philosophy, that as the living body is admittedly composed of the common elements of matter; that as those elements are in most organic substances known to be combined in strict accordance with the laws of chemical affinity; that as, in a multitude of instances, to which the exact science of the present day is continually adding, it is recognised by all that the actions of the living body are either chemical or physical in their character, so in reality is proved the operation of physical forces, and that all the so-called vital actions are as essentially dependent upon these same forces."

We cannot discover from this statement, if the Lecturer's words be accepted literally, that he has started any novelty in doctrine. It is true that he is not very precise in his terms: he appears to make a distinction between a conscious and a spiritual existence, as if the soul or spiritual existence were something different from the entity which ministers to consciousness—a distinction which, though expressed in a form of words, we do not believe he intended in idea; but he admits that life is not a property of primitive matter, by accepting and enunciating the doctrine that God breathed the breath of life into the body of man when He formed him out of the ground. Now, if the forces producing life were inherent in matter, there would have been no necessity for such an inspiration of a new force by the Divine Creator. Then, up to this point, we say again that Mr Grainger merely re-affirms old doctrines.

But, as he continues, he seems to us to get entangled in an illogical maze, owing, apparently, to a desire to connect the affirmations of revealed religion with the modern doctrine of the correlation of forces. His last sentence, as quoted in the MEDICAL CIRCULAR, crystallises his thought. He says: "From these and similar considerations, he was satisfied they might rightly conclude, that save and except the sentient and truly living soul, every part and organ of the human body was formed of the common elements of matter, combined by *pure* physical and chemical forces, and acting *exclusively* in obedience to these forces." He denies, in another place, that there is anything "special" in these forces. Then, if there be not, how comes it that it was necessary for the Divine Maker to breathe the breath of life—or, in other words, to infuse a new principle—into the body of man, which he formed out of the "common elements of matter?" It would seem from the context, however, that Mr Grainger does not believe that God breathed the breath of organic life, but simply the spirit, into the body of man, which spirit has no connection whatever with the organic life. This confusion has arisen from Mr Grainger having used the word "life" in two senses—the one its understood scriptural sense, and the other its physiological sense, as taught by himself and the school of thinkers to which he belongs.

Mr Grainger's doctrine, then, is that all the actions and functions of the living body are consequences of certain properties of matter, developed into activity by the relations and conditions of organisation. He repudiates, in short, any vital principle, as independent of the inherent properties of matter. He recognises two existences alone—matter and spirit. These views are not new, and the first has in recent times been stated in a variety of turns of language by several theorists. It is obvious that the spirit has nothing to do with vitality according to Mr Grainger's theory; for although he rounds off a series of fine sentences in acknowledgment of the existence of an immaterial essence, yet it seems to us to look very much like a superfluity in his philosophical scheme. If matter organised in a specific way develops certain properties which bestow upon it all the characters of vitality, it is obvious that the spirit of man is unessential to life. We should like to know how Mr Grainger would explain the phenomena of sensation and thought?

Mr Grainger disposes of John Hunter's vital-principle doctrine with easy sufficiency; yet, after all, his own teachings are not satisfying. We might be prepared to admit that matter has other properties than those exhibited in its inorganic state, and that it is possible that there may be other combinations of matter than those with which we are familiar, evincing qualities of which we can have no conception; and yet we might not be willing to admit the non-necessity of an ever-present and acting sustaining power, without the aid of which the peculiar phenomena called life could not be manifested. The point is this: Is ordinary matter endowed with latent qualities which, under certain conditions of organisation, become developed into activity and produce the phenomena of life; or was there superadded to matter, at the first creation of its organised types, certain forces which enabled it to manifest certain activities? In either case the phenomena of life would be due to the properties of matter; but the first position pre-supposes that oxygen, hydrogen, nitrogen, and carbon possess essentially certain latent and inseparable properties which, by a fortuitous combination of their atoms, are brought into operation, and enable them to constitute a man; by the other, that certain

new forces are impressed upon matter adequate to the development of life in its various types, which forces have been erroneously, perhaps, called "vital forces," the real meaning being that they are forces with which matter is endowed, but peculiar to it in certain conditions. It is not, therefore, admitted that oxygen or any other gas possesses this desiderated force simply as an essential property of matter; and it is consequently denied that it could ever endow itself with such a force, or that any combination of gases could create a force which neither of them originally enjoyed. The affirmative of this doctrine was once called materialism; but philosophy has now become liberal and euphemistic. We do not, therefore, stigmatise this notion as materialism, but we say that it is only theory—a theory as old as philosophy itself, and in support of which Mr Grainger has not added any argument of intrinsic importance. In some respects his arguments are fallacious: for instance, when he says that "Dr Richardson has shown that the coagulation of the liquid fibrin was owing to the loss of its ammonia," he obviously commits an error of reasoning. Liquid fibrin would no more coagulate than water would on the liberation of ammonia, unless there was some force operating to cause the coagulation. The extrication of ammonia is not the efficient cause of the coagulation; and we do not remember that Dr Richardson has ever asserted that it is so.

Again, an ultra-spiritualist may allow that the phenomenon of cell-growth is a property of matter—a property independent of and in addition to its ordinary properties, as exhibited in a block of marble—and yet affirm that this admission does not settle the question, nor would a hundred more of a like nature. All we can say is, that it is a property of living organised matter to form cells; but it must be living to do so—therefore there is a precedent cause of action, which is the *primum mobile*. It might be easier to show that an antecedent principle of vitality—call it by what name we may—is necessary to the manifestation of these properties of matter than that these properties came to be developed by some fortuitous combination of its atoms.

Dr Wilks's address dealt with subjects of a more special clinical nature. He stated doctrines apparently paradoxical about the existence of acute disease. He wished to show that nearly all acute diseases were originally chronic—that is to say, that there was a pre-existent disturbance of the functions or lesion of the structure of an organ in most instances of acute outbreak. It is well that the position should be boldly stated, as it will tend to direct attention more closely to the insidious approaches of disease, as well as to its more lasting but less urgent conditions. It is, however, a doctrine that must be limited in its application by the use we make of the word "acute." Like many other similar statements, it is brilliant at the first glance, but loses much of its importance as we penetrate the exterior circle of phosphorence. It is a doctrine, however, that would have been promulged only by so proficient a pathologist as Dr Wilks.

Mr Savory expatiated eloquently on the importance of industry to the student, and cited numerous illustrations to show that what is called "genius" among men meant, generally, an extraordinary capacity for labour. Mr Savory is right: no fool, indeed, can become a genius by mere plodding, but no mere clever man ever become a genius without it. Nine parts in ten of genius, as exhibited in its works, is industry.

The only other address on which we shall comment is that of Dr Barnes. This was composed in a style of sustained eloquence, exhibiting the dignity of the Profession of Medicine, and presenting many useful suggestions for the guidance of the student. On the whole, the orations are this year creditable to the Professors, and will reward the reader who has devoted an evening to their careful perusal. These annual orations must be productive of good, by maintaining an elevation of tone both among teachers and pupils, and offering questions both in philosophy and morals which are apt to be lost sight of in the routine of elementary study, and the exigencies of the dissecting-room.

SUMMARY OF THE WEEK.

THE ARMY MEDICAL SCHOOL.

At length the grand desideratum of Military Hygiene has been accomplished in the institution of the Army Medical School. Last week Mr Sidney Herbert visited the Hospital at Fort Pitt, and opened the School. He perambulated the wards of the Hospital, and inspected all the subsidiary arrangements, with which he declared himself satisfied. In the course of some sensible observations, he stated the gratifying fact, that owing to the improvements that had been introduced in the management and sanitary discipline of the Army, the health of the troops was higher than that of any other Army in Europe. Major-General Eyre also congratulated the Medical Officers on their improved position; so that a fresh *couleur de rose* was thrown over the proceedings. Professor Longmore delivered the Inaugural Address, and auspicated a bright and useful career for the new Institution. Everybody was pleased; and, looking at the importance of the occasion, they had every right to be. The more Medicine is held in consideration in the Army, the greater will be the advantages both to officers and men. The blunders and sufferings of the Crimea were caused by a culpable and supercilious neglect of the laws of Hygiene, and of the expostulations of the Medical Staff. That war taught the country a lesson, the fruits of which we are now beginning to realise.

ARSENIC-EATING.

It appears that this figment of arsenic-eating is received with ready credence even by some Professional men who are well acquainted with the action of arsenic on the human system. In the course of the examination before the magistrates into the charge of poisoning Miss Adamson of Wakefield by means of arsenic, Dr Waddington expressed his belief that "it is a well-known fact that in Basle, and all through the mountainous parts of Switzerland, arsenic is taken by the mountaineers to sustain their health." This may be "a well-known fact," but it is the first time we have heard that arsenic-eating is customary among the Switz mountaineers. It is surprising to us that throughout the numerous letters that have recently appeared in the public journals on Alpine travel and training, not a word should have been said about this alleged practice. A few months ago, we found it necessary to comment upon a similar statement made by M. Heisch with reference to the Styrian peasants; and we implored M. Heisch to produce, in the interests of science, a single confirmed arsenic-eater—one of those men who, he said, could swallow twenty-three grains of arsenic with impunity. We offered a handsome reward; but the man has not been forthcoming. Now, as Dr Waddington has announced in a Court of Law his belief in a similar phenomenon, we hope that he will feel it to be his duty to sustain his evidence by the production of a Mount St Bernard Guide who has been in the habit of eating arsenic, or who will not object to swallow half-a-scruple in the presence of the Judge of the Midland Circuit or the President of the Medico-Chirurgical Society. As arsenic-eating is said to invigorate the system, we venture to predict that such a daring act performed in the face of an admiring world will confer upon the man the privilege of immortality—at least, in the records of toxicological science. Should Dr Waddington not be able to afford the time to go to Switzerland, he may perhaps meet with a suitable case for evidence among the inhabitants of the little village of Whitbeck in Cumberland, who are reported to grow fat and rubicund upon an arsenical water that flows from the Blackcombe mountains. We refer him to a paragraph in our column of news, where he will find a full and particular account of these wonderful villagers. It is fortunate for science that a colony of arsenic-eaters has been discovered in this country; so that the *savans* of England will have an opportunity, without going abroad, of expounding this great mystery. Is there no physician at Whitbeck to write about the virtues of this

stream, and elevate the village to the dignity of a Spa?

THE 'AKBARE TUBABUT.'

We have lately received a circular covered with a multitude of double dots, and zig-zag and semicircular scratches, which, we are told, represents the Oordoo, and announces the publication of a Medical Gazette in that language. This is one of the most important signs of the times, and proves to our mind that India is undergoing a rapid and momentous change. Whilst Editors of newspapers are discussing in the interest of their rival parties the Condition of India question, and deploring the ignorance of the people, and the hopelessness of our efforts to introduce among them the elements of modern science, here comes a fly-leaf which gives better testimony as to the state of India than all their elaborate disquisitions. The Hindoo Native Doctors and Hakims are about to be instructed in the science of Medicine as taught in our European Schools; and as the Editor of the 'Indian Lancet,' who seems to be the adventurous genius that has started this journal, has probably an eye to profit in the undertaking, it may be justly assumed that there is already a reading public in Hindostan sufficiently imbued with the truths of European science to make the speculation a feasible one. We cordially wish that this adventure may be successful, and that the Editor of the 'Akbare Tubabut' will be rewarded for his public spirit by a large circulation.

ADULTERATION IN THE CITY.

The City of London has done itself honour in authorising its Medical Officer of Health to carry out the provisions of the Act, passed during the last Session of Parliament, for the prevention of the adulteration of food. How this measure will work will now be proved. Whatever good can be obtained from it will no doubt be secured under the ablo superintendence of Dr Letheby. There will be one practical difficulty in the carrying out the measure which will probably prevent its adoption in many boroughs—viz., the expense. It appears that the fees are placed so low—varying from two shillings and sixpence to ten shillings and sixpence—that they will not cover the disbursements incurred by the necessary analyses. The excess must therefore be borne by the Borough. In all Vestries and Town-Councils there is a considerable number of persons whose presumed interest it is to hinder the operation of the Act, and who will therefore be glad of the excuse which the expense offers for opposing its application. Nevertheless, the passing of this Act is an important step in the right direction; and if its adoption should be proved useful in the City of London, that example must be followed in all the provincial boroughs. In process of time this enactment will be considered to be one of the most important that ever received the sanction of the Legislature. The abominable and pernicious practice of adulteration will be effectually suppressed, and the poor man, as well as the rich, will be provided with the first condition of health—genuine and wholesome aliment.

THE MELBOURNE HOSPITAL.

The movement for the extension of our Hospital Staffs which we have been, for some years, pressing forward in this country, has been commenced in Melbourne, by Dr Mackenna. The Melbourne Hospital had, in the year 1858, 200 beds, and two physicians and two surgeons on the Staff. Dr Mackenna considered that this number was not sufficient; and he found, moreover, that the patients were badly attended,—the mortality among them being so high as fifteen per cent.: he therefore urged for an increase of the Medical Staff. During the year 1858, a new wing was opened, thereby increasing the accommodation of the Hospital to 350 beds; and, at the same time, the number of the Staff was doubled. Dr Mackenna was still dissatisfied, and demanded that the Medical Staff should be increased to twelve. Hence arose an angry controversy: jealousies sprung up; Dr Mackenna was vituperated, and, at length, this gentleman—in self defence, as he says—brought forward three distinct charges of mal-treatment. These were submitted to the investigation of the Committee, who, in their Report, exonerated the Staff, whilst they condemned the system, thus taking a pattern out of the Blue Books of the mother-country. The following passages of the Report deserve attention:

"With a view to increased efficiency in the Medical department, we have had under our consideration the expediency of increasing the regular Staff of the Hospital, but upon the whole we are of opinion that at present no such increase is required. In order to relieve the great pressure of business arising from the out-patients, it appears to us that it would be desirable rather to adopt a suggestion thrown out by Dr Youl of establishing Branch Dispensaries in different populous localities, to which one or more Surgeons or Physicians might be appointed by the Hospital Committee. By such an arrangement, the business of the central establishment would be effectually relieved; the great bulk of those who now frequent the Hospital as out-patients would, with much more convenience to themselves and their families, attend the local institutions; whilst, at the same time, a system of domiciliary visitation might be instituted which would be of immense advantage to the poorer classes, and tend, it is to be hoped, to lessen materially the enormous mortality which at present prevails among the infantile branch of our population: the opportunities, too, of accumulating experience would be more generally enjoyed by the Medical Profession.

"We do not imagine there would be any difficulty in settling the conditions on which these auxiliary establishments might be made dependent on the parent institution, or any indisposition on the part of the Government to extend the annual Hospital Grant, so as to bring it in relation to the enlarged sphere of its operations.

"Another mode by which the efficiency of the Hospital might be promoted, would be by the establishment of a Convalescent Asylum. On this question, however, we do not at present propose to enter at large; only we desire to express our belief that the time is not distant when a distinct and tangible mode of carrying out this object will be presented to the Governors."

THE SOCIAL SCIENCE MEETING AT GLASGOW.

The Annual Meeting of the Members of the Association for the Promotion of Social Science has been recently held at Glasgow. With the exception of a grand oration *de omnibus rebus* by Lord Brougham, there was little said or done at this meeting to fix public attention. There is a risk that the efforts of the Society will be dissipated among a countless variety of topics, without benefiting in any important degree any single department of social exertion. If the Society have not failed, it certainly has not succeeded. The business done in the Sanitary Committee was very trivial. Dr Lankester made his usual speech, with his usual ability, about foul wells, and the Glasgow people promised to attend to his suggestions; and this was about all that was done in this department. This was a very lame embodiment of the state of modern sanitary science.

THE SPIRIT OF THE PERIODICALS.

(Continued from page 241.)

"*Case* 656.—On August 24, 1853, I was called to an alarming case of uterine hæmorrhage in the Edgware road. An immense quantity of blood had been rapidly lost, and the strength of the patient was extremely depressed. The entire os uteri was covered with the placenta. I experienced little difficulty in passing the hand into the uterus, turning the child, and removing the placenta; but the hæmorrhage continued undiminished after the placenta had been removed, and she soon died. In this case, perhaps, the result would have been different if the delivery had been sooner completed; yet there was little time lost."

"*Case* 658.—On October 15, 1853, at 12.30, I was requested to see a lady residing at West row North, who was in the 7½ month of her first pregnancy, and who had been seized with convulsions without any premonitory symptoms. She was insensible. The os uteri a little dilated; face presenting; membranes not ruptured. Ten ounces of blood had been drawn from the arm, leeches to the temples, and a turpentine enema given. At 3 p.m. she had had one attack; labour progressing. At 6 p.m. went and found the child born dead by the natural efforts. Placenta retained half an hour; came away after pressure and gentle traction. About two hours before, Mr —— had given two drachms of chloroform. Three or four fits followed delivery, but her consciousness gradually returned.

"*Case* 659.—Mrs B——, aged 36, November 29, 1853. Has had seven children. At the last confinement, three years ago, Mr Jay found a small tumour in the pelvis, behind the uterus, which rendered the labour very protracted. She recovered favourably. Her eighth labour commenced yesterday. The membranes ruptured two days ago; Mr Jay has been in attendance since nine last night; no progress during the last eight hours; violent pain and constant straining; the progress of the head is impeded by a soft irregular mass behind the uterus, which is pressed down during each pain by the head; the head is squeezed between this and the front of the pelvis; ears not felt; impossible to apply the short forceps; there appeared to be danger of rupture of the uterus, and mischief from pressure; we resolved to open and extract the head, which I immediately did, and the recovery was favourable.

"*Case* 660.—Mrs B——, March 15, 1855. Labour at the full period commenced yesterday, and has continued all night; the head cannot pass the tumour in the back part of the pelvis; I opened and extracted the head without much difficulty. At the 7½ month Mr Jay and I met in consultation, to consider whether or not premature labour

should be induced; we thought the tumour had not increased since 1853, and that, if the child were small, it might pass alive at the full period. This opinion proved to be incorrect; the recovery was favourable.

"*Case* 661.—Mrs B——. On Tuesday, November 24, 1858, with Mr Jay, I perforated the membranes about the 7½ month. My impression was that the tumour had not increased. On Friday night, between seven and eight, of the 28th, the pains came on, and the child was readily expelled, but dead, about a quarter to twelve, and had been dead some time. The patient stated that she felt the movements at the time the membranes were punctured. The patient again recovered favourably, and is, I believe, at this time in good general health."

Mr JONES contributes the following article on the *Treatment of Delirium Tremens by large Doses of Digitalis* to the 'Medical Times and Gazette' of the 29th ult.:

"Having just had an opportunity of showing to some Medical friends from London—Mr Spencer Wells, Dr Ballard, and Mr McCrea—the effects of large doses of digitalis in the treatment of a very severe case of delirium tremens, and having been strongly advised by them to make my experience of this mode of treatment known to the Profession, I gladly do so by means of the 'Medical Times and Gazette.'

"About twelve years ago I was called to see a patient with delirium tremens, residing about a mile from my house, who was almost *in articulo*. I prescribed a dose of chloric ether with tincture of opium; but the wife, who came for the medicine, took, by mistake, a phial containing *one ounce* of tincture of digitalis. I discovered the error, and was horrified when I heard that the patient had taken this dose; but no less surprised than pleased when I also heard that, instead of being poisoned, he was very much better. Under ordinary treatment, I fully believed he would have died; but after this single dose he rapidly recovered. Profiting by this hint, I began to give digitalis in all the cases of delirium tremens which came under my care in hospital and private practice; and during the last twelve years I have adopted it in at least seventy cases—this effect of drunkenness being very common in Jersey.

"As to the dose, experience has taught me that the best dose is *half an ounce* of the tincture given in a little water. In some few cases, this one dose is enough; but generally a second dose is required four hours after the first. In some cases, but very seldom, a third dose is called for; but this hardly ever exceeds two drachms. The largest quantity I have ever given was *half an ounce* at first, *half an ounce* four hours afterwards, and another *half-ounce* six hours after that—making an ounce and a half in ten hours.

"As to the effects of these doses, my impression is that the action is on the brain, not on the heart. The pulse, so far from being lowered in force, becomes fuller and stronger, and more regular, soon after the first dose. The cold, clammy perspirations pass off, and the skin becomes warmer. As soon as the remedy produces its full effect, sleep for five, six, or seven hours commonly follows; sleep is the guide as to the repetition of the dose. No action on the kidneys is evinced by any unusual secretion of urine. Sometimes the bowels are slightly acted on, but not commonly. I have never once seen any alarming symptom follow the use of these large doses of digitalis. The only case I have lost since adopting this treatment had a tumour in the brain. In three only was other treatment adopted after digitalis had failed to procure sleep; in other words, in sixty-seven out of seventy cases digitalis was the only medicine used, and sixty-six of these patients recovered. I do not mean that these are the exact numbers of those treated; I am certain as to the death, but I may have had more recoveries. I am well within bounds in saying seventy cases in twelve years, and that all of them were well-marked cases of delirium tremens. Slight cases of nervous derangement after drinking I have seen in great numbers; but I speak here only of such cases as required active treatment. My previous experience of the results of the treatment by opium or some of its preparations, by anti-spasmodics, &c., had certainly been much less successful; the proportion of deaths was larger, and the recovery much less rapid. Again; I have treated more than one patient successfully by digitalis, who, in subsequent attacks elsewhere, has been treated by opium and died; and in many of the cases in which I have used digitalis successfully, opium had been previously given without any good effect.

"I will only allude to one case in illustration:—On September 9, 1860, I was called to see a gentleman, 48 years of age, who was in a very alarming state, having been without sleep four days and nights, having been 'muddled' for two months before, and having previously had 'fits of the horrors.' He had been treated by another Practitioner by opium in moderate doses, but had become worse, and when I was sent for it was the opinion of Mr Spencer Wells and Mr McCrea—who accompanied me in my first visit—that the case was as bad a one as *they* had ever seen; certainly *I* never saw a worse. The pulse was almost imperceptible; the skin covered with cold, clammy perspiration; the face deadly pale; the lips blue; the hands tremulously grasping the air; the eye expressive of great fear; the mind gone; he was muttering incoherently. With some difficulty I passed half an ounce of tincture of digitalis down his throat in the presence of my friends. In a few minutes he became more tranquil, the pulse was felt more easily, and we left him. After four hours I found that he had not slept; but he was rather more sensible, less tremulous, and warmer. I accordingly repeated the dose. Three hours after that, as he had been still without sleep, though in other respects improving, I gave two drachms more, making ten drachms in seven hours. After this he had some sleep, and had slept at intervals during the night. The next morning Dr Ballard saw him, with my other friends, and all of them were much pleased with the great improvement manifested. He was sensible, his fears had disappeared, he was very slightly tremulous; the skin was warm, the tongue moist, and the pulse full and regular at 90. The heart's sound and impulse were normal; the bowels had acted once, and urine had been passed in natural quantity. After this he took some broth, drank freely of imperial and lemonade, but took no stimuli of any kind, or any other medicine. He slept uninterruptedly for three hours and a half in the afternoon, and at intervals in addition. The next night was a good one; and when he was seen by my friends again the next morning he was almost well, and calling out for a mutton-chop.

"I trust that this narrative of the result of my experience may induce others to follow what I believe to be a very valuable practical lesson; but I must warn those who do so not to try, as I have done, any smaller doses than those I have recommended. They would not only lose valuable time by so doing, but, I believe, would do harm. Doses of half-a-drachm or a drachm do no good whatever; and the pulse, in some cases where I tried them, became intermitting. I have never seen this effect from the larger doses; on the contrary, a feeble intermitting pulse has generally soon become fuller and more regular, proving, I think, as I said before, and as I again wish to impress on the Profession, that the curative action is on the nervous system primarily, and not on the organs of circulation."

We extract from the 'Dublin Medical Press' the following report of three cases of *Dislocation of the Hip-joint*, by Dr J. MORRISON, of Newry:

"*Case* 1.—In December last, a strong, healthy-looking farmer, aged sixty-six, whilst in the act of getting into a market-cart, was thrown over one of its wheels, in consequence of the horse moving suddenly and unexpectedly forwards. Some friends who were present immediately lifted him into the cart, and he was at once driven home to the country—a distance of four miles. Being unable to move his limb, on the following day he sent a messenger to request I would visit him. On examination, the usual symptoms of dislocation on the ilium were very well marked—the knee and toes turned inwards, and the limb at least two inches shorter than its fellow, &c. &c. Having had no information as to the nature of the injury till I saw the case, I was quite unprovided with any sort of appliance, but determined to attempt the reduction by the aid of such means as the house afforded. The man was placed on his uninjured side, the leg of the dislocated limb was well bent on the thigh, and the thigh on the pelvis; the limb was then drawn from the other, and being made to act as a lever, was rotated and jerked strongly outwards for some time; but this procedure gave so much pain as to make him say he would not submit to it any longer. As he had an insuperable objection to bleeding, as anything like a proper warm-bath could not be procured, and as I learned that he had never used tobacco in any form, I determined to subject him to the effects of a well-charged pipe. After smoking eight or ten minutes, he became very sick; cold perspiration flowed freely; he was thoroughly relaxed. Extension with counter-extension well applied, by the assistance of sheets and powerful men, was now resorted to, and kept up a considerable time, the limb during this period having been strongly and frequently rotated; but notwithstanding all these efforts, there was no indication of a successful result. All the bandages were then taken off, the leg was bent on the thigh and the thigh on the pelvis, the limb drawn from its fellow, made a lever of, and jerked and rotated suddenly outwards, *as at the first attempt*, when the head of the bone jumped almost immediately into its socket.

"*Case* 2.—A sailor, aged thirty, was imprisoned for drunkenness in the Ballybot Bridewell here in April last. During the night, and before he became sober, whilst attempting to climb up to a window, with the view, as is supposed, of effecting his escape, he fell backwards over a table and dislocated his hip-joint. He was visited by a medical gentleman early next morning, and was sent to the Newry Hospital, where I saw him about ten o'clock. The dislocated limb was about an inch and a half longer than the other; the hip was quite flat, contrasted with its fellow; there could be no doubt but that the head of the bone rested in the thyroid foramen. The man looked jaded as after a debauch. I placed him on the uninjured side, relaxed as much as possible all the muscles of the affected limb, seized it firmly as a lever, drew it across its fellow, rotated and jerked it forcibly inwards, when, in less than two minutes, the reduction was effected.

"*Case* 3.—A man, aged about forty, who works in a foundry here, was sent to the Newry Hospital about three weeks since, and gave me the following account:—On the 16th July last, while engaged at work on a ladder about ten feet from the ground, he fell on a boiler, which broke his lower jaw, knocked out two or three teeth, and wounded his head in several places. He was greatly stunned, was unable to rise, and felt severe pain in the right hip. Two medical gentlemen were quickly in attendance, and had him removed to his house, where they did all they could to alleviate his sufferings. The hip was examined, but, whether from swelling or other causes, no special injury was detected.

"The right limb, when I saw him, was fully two inches longer than the left, was moderately bent on the pelvis, and slightly inverted. The flatness of the hip compared with the other was very apparent, and the head of the bone could be distinctly felt at the upper and inner part of the thigh. The displacement was plainly into the thyroid foramen. Knowing that the reduction in this case would be very difficult, if not impossible—the dislocation having occurred six weeks and three days previous to his being sent to hospital—I had everything provided which I thought would be conducive to its accomplishment. He was placed on a mattrass on his sound side, and put fully under the influence of chloroform, when the dislocated limb was extensively moved in all directions for the purpose of breaking the new adhesions. By way of thoroughly tiring the muscles, pulleys were now applied, and the limb kept well stretched for about fifteen minutes, strong transverse force being at the same time used at the groin for the purpose of drawing the head of the bone outwards; but still the latter held firmly to its seat. The pulleys and bandages were now all removed, when the limb was treated exactly as in Case No. 2. In less than five minutes I had the satisfaction of seeing it completely restored to its former position.

"In making a few remarks on these cases, I may mention that in the first one, as no means were adopted to produce sickness or anæsthesia previous to the primary attempt at reduction, and as the hip was painful and considerably contused from the fall, the movements necessary in using the limb as a lever were very badly borne, and consequently this first trial did not get fair play; and although extension was then well applied, and much favoured by the relaxed state of the muscular system induced by the tobacco, yet it failed to produce the desired effect. In all probability, however, it may have been of benefit in so weakening the muscles as to render them

more amenable to further trial. Accordingly, when they were immediately afterwards relaxed, and the lever power brought into use, the reduction was easily effected. But I am strongly of opinion that this would have been accomplished by the hands alone, had the sickness been produced prior to the making the first attempt. And I may here observe that it may be well to hold the tobacco in view where no chloroform nor tartar emetic is within reach; also, that dislocation of this joint is a rare accident at the age of sixty-six.

"In the second case the reduction was at once accomplished by merely relaxing the muscles, and using the limb as a lever.

"The third case seems interesting in several points of view, but chiefly from the dislocation having been reduced without any great trouble after the lapse of six weeks and three days. Mr Fergusson, in his very useful volume on Practical Surgery, says:—'I have myself seen attempts made in various instances of old standing, but have not witnessed a successful effort beyond the period of three weeks. Sir Astley Cooper has described instances of a more fortunate kind, after the lapse of four, five, six, and seven weeks.' The extension which was resorted to, by fatiguing the muscles as in the first case, may have been conducive to the desired object; but as no effectual change was made in the position of the bone until the muscles were well relaxed and forcibly acted on by using the limb as a lever, I should be inclined to attribute the success of the operation chiefly to the latter proceeding. The effects of the chloroform were excellent. Complete anæsthesia was kept up during the entire time of the operation, and of course the muscles were quite passive."

SKETCHES OF EMINENT PHYSICIANS AND SURGEONS OF THE LAST CENTURY.

By JOSHUA BURGESS, M.D.

MEMOIR OF JOHN HUNTER, F.R.S.

(Continued from page 214.)

This trial of Sir Theodosius Boughton brought the character and temper of John Hunter conspicuously into public criticism. Nor was it at all sparing; he incurred all kinds of censure, and even his friends contemned and apologised for him. Some of the latter went so far as to say, he was so confused that his mind was not consistent, and had become inextricably lost in a maze of hesitation and doubt. We, who have gone through all the incidents of this eminent man's career and life, are free to say that none of them redounded more to establish the clear-sighted, discreet, and judicious attributes which constitute the man of philosophy and science, than did the evidence he gave on this trial of Captain Donellan for the murder of Sir Theodosius Boughton. To every question asked of him by the Court and Counsel, he gave a clear, calm, and conclusive reply. If the evidence came short, the fault, as John Hunter justly inferred in reply on his examination, was, that the *post-mortem* was made when putrefraction had taken place, and that no autopsy having been made of the head and intestines, the only chances of its throwing any light upon the case was missed. Others, carried away by a provincial sensation, were contented with guessing, and boldly affirmed with no other support than surmise and supposition. The Judge, who, no doubt, was anxious to act conscientiously, wondered at the doubt of one who was only to be moved by the evidence of atern natural facts. The learned Judge, in a sort of desperation, speaking of John Hunter's evidence said, "He does not appear to have formed any opinion at all in the matter," and he "conceived it might be ascribed to other causes, since the evidence, independent of other circumstances, was so very slight." The Judge was evidently floundering, and by accident made a correct admission; for truly John Hunter had not, and stated that he had not, formed any opinion "in the matter."

The paper he communicated to the Royal Society in 1787, describing the 'Functions of the Ovarium,' obtained for him the gold medal, as already stated. As it is our office to endeavour to depict this wonderful man as we find him, we cannot refrain from relating another highly characteristic, although not very flattering, anecdote. Being consulted in a curious and interesting case, which terminated fatally, he begged to be permitted to make a *post-mortem* examination. Having been firmly denied, "I saw," continued the narrator, "by his countenance, that a storm was brewing." He, however, "gravely and calmly addressed the master of the house in the following manner:—'Then, sir, you will not permit the examination to be made?' 'It is impossible.' 'Then, sir,' said Mr Hunter, 'I heartily hope that yourself, and all your family—nay, all your friends—may die of the same disease, and that no one may be able to afford any assistance.'" Notwithstanding this temerity—we may, perhaps, better say, unrelenting devotion to inquiry after facts and evidences of disease—he was a very timid practitioner. Sydenham was equally dubious and hesitating, and could with difficulty decide upon his prescriptions. His custom was to tell his patients to call again, when he would prescribe for them; by which means, as they did not return, he lost his fees. John Hunter often was known to say—"I cannot tell at present what to recommend—I must think of it." He thus made every case a study. His habit, as Abernethy relates, was "to distrust opinions, and examine every subject for himself." He used to say, "We are beginning to learn our profession."

As our narrative approaches the last stage of John Hunter's life, and as its chequered incidents afford ample elements to give an analysis of the finer and more subtle shades of character, a slight summary will not be out of place for that object. We must premise that he was not imbued with idealism. Although sensitive in an uncommon degree, no great refinement of feeling existed to exaggerate that irritable state of mind. Bacon says—"He that is only real, had need have great parts of virtue, as the stone had need to be rich which is set without foil." The realness of John Hunter's character constituted its distinctive quality. It discovered him by its singularity, and came home to the heart and feelings as much by its rarity as its originality and simplicity. It was manifested in little as well as in great things—in his virtues and failings, in his moments of leisure and in his moments of labour. This quality, no doubt, rendered it a difficult task to accommodate himself to the ways which win in life; yet he calculated to win by other ways, and without their aid. Hence resulted indomitable perseverance and intense labour. He was too real not to quarrel with neglect, and too honest to disguise his feelings. He had other impediments of character, against the injurious influence of which he would have appeared to have struggled but little. With no refined, gentlemanly feelings, nor yet conciliating manners, he was apt to be rude and overbearing from conscious superiority. He carried somewhat of the "pride of port," derived probably from his military associations. John Hunter despised the minor tactics used for "rising in the world." These qualities prevented him from becoming a favourite in the Profession, and made him enemies. Notwithstanding this apparent want of amiability, those who best knew him spoke of him in affectionate terms. The common expression, when speaking of him, was, "the dear man." Hunter was greatly addicted to swearing, which, at that time, was a common mode of speech, even amongst the exalted classes. Mr Lynn, who often called him in consultation, and who had himself been an especial object of his disinterested regard, bears free testimony to his generosity. On such occasions Mr Lynn found him in the dissecting-room: he would lay down his dissecting-knife, and say, "Well, Lynn, I must go and earn this damned fee, or I shall be sure to want it to-morrow." Mrs Hunter was a woman of refined manners, and fond of society. Her husband, on the contrary, preferred scientific conversation, when he could glean something. On one occasion, "on returning home late, after a hard day's fag, he unexpectedly found his drawing-room filled with musical professors, connoisseurs, and other idlers," assembled by Mrs Hunter. "Greatly irritated, walking straight into the room, he addressed these astonished guests pretty much in the following strain: 'I know nothing of this kick-up, and I ought to have been informed of it beforehand; but as I am now returned home to study, I hope the present company will retire.' Followed by *exeunt omnes*." This difference of tastes was not attended with further unpleasantness. They were much attached, and the connection was a source of great consolation. They had four children; two died young, and two survived—a son and daughter. In short, John Hunter was especially blest with the gifts of this world—a wife who was a suitable companion in every way, and children who contributed the delights of existence to the last. He manifested and expressed a real relish of life and its enjoyments.

He placed great confidence in the extensive reading and scholarship of Mr Cruickshank, F.R.S., who was one of the medical attendants of Samuel Johnson in his last illness. This gentleman, educated for the Church, was a man of great ability, of classical tastes and popular manners. He, with Dr Baillie, carried on the School in Great Windmill street after Dr Hunter's death. He published upon the Nerves and Absorbents, which was translated into several languages. On Hewson separating from Dr Hunter, Cruickshank succeeded him. He and Dr Hunter agreed very well, identifying himself as he did with the Doctor's views and tastes. He also lectured; which was a bold undertaking—to place himself in comparison with William Hunter, who was unequalled as a lecturer. He nevertheless sustained the comparison, and passed this ordeal with great *éclat*. But even with Cruickshank, "whom Dr Hunter first took as librarian and assistant, it often required the mediation of mutual friends to preserve an intercourse extremely useful to the one, and almost necessary to the other." When John Hunter made a discovery, it was his custom to relate it to Mr Cruickshank, who frequently, to his no small mortification, informed him that Haller had described the same thing before." *a*() In 1783 he read a paper of his brother's, at the Medical Society of London, 'On the Uncertainty of the Signs of Murder in the Case of Bastard Children;' a very eloquent and argumentative paper. His 'Treatise on the Blood, Inflammation, &c. &c.,' in which he broached his favourite opinions of the seat of life in the blood, were very crude. They no doubt were influenced by the metaphysical disputes of the day, and show a strong tendency to establish physiological facts in opposition to materialism. He says, "I shall endeavour to show that organisation and life do not depend in the least on each other; that organisation may arrive out of living parts and produce action, but that life can never rise out of or depend on organisation." He became completely mystified. It would be useless and unprofitable to state his reasoning or to analyse his arguments upon this subject. It is said that "he did not adopt this opinion from the Bible, Alkoran, or Harvey; but it arose spontaneously from his own investigations and experiments." John Hunter most unphilosophically considered life to be an abstraction. Thus we find in him no faculty of comprehending subjects upon a large scale. He never travelled beyond the details of anatomy or natural history, connected with anatomy and elementary physiology. The nervous system never came within the scope of his investigations. John Hunter had no creative or imaginative faculties, and no high moral attributes. His claims as a naturalist and physiologist consist in having been the type of industry, patience, and perseverance. He had strong prejudices, and was not very tolerant. He had more faith than his brother. Physiological inquiry was a novelty in his day; for accuracy he was unrivalled, and for audacity and ambition he excelled contemporaries. But for that exalted science and genius which are associated with the names of Bacon, of Harvey, and of Newton, John Hunter prefers no claim. This work on the 'Blood,' &c., and his work on 'Gunshot Wounds,' he dedicated to the King in 1790, in acknowledgment of "your Majesty's appointment to one of the most important appointments in the Medical Department of the Army." The numerous preparations he contributed to his brother Dr William's collection laid the foundation of the magnificent museum he bequeathed to the University of Glasgow. Mr Gulliver, in his edition of Hewson's Works, says, "The Windmill-street School no longer exists, but it will be preserved from oblivion by the names of the eminent men who lectured there. Among them the future historian of anatomy

(*a*) 'Adams' Memoirs,' p. 235.

and physiology in England will have to commemorate William Hunter, Hewson, Cruickshank, Sheldon, Baillie, Brodie, and Charles Bell."(b) John Hunter did not obtain so wide a European fame as his brother William. Whether this is to be explained by the more practical nature of Dr William Hunter's inquiries, his superior scholarship and style of writing, or from the unacknowledged aids he received from John, it is certain that Dr William enjoyed a more extensive reputation on the Continent.

GENERAL CORRESPONDENCE.

PENAL LEGISLATION FOR THE MEDICAL SUPERINTENDENT OF THE CRIMINAL LUNATIC ASYLUM.

To the Editor of the Medical Circular.

SIR,—On a recent occasion you were, with your usual courtesy, kindly pleased to insert in your independent publication a letter from me, calling attention to an Act passed, at the close of the last Parliamentary Session, for the erection of an Asylum for the Criminal Insane of England and Wales; a measure long and much required, but unfortunately having contained in its enactments penal provisions for the due punishment of the Medical Superintendent with the keepers and nurses of that institution *in embryo*, which can be looked upon in no other light than a great scandal to and most unmerited insult upon the whole Medical Profession. And again, I must express my astonishment that that long-established and influential "Association of Medical Officers of Asylums and Hospitals for the Insane" was so entirely neglectful of its solemn duties as not, at least, to have made the appearance of a stand against this gross indignity to its important specialty; but nothing of the kind would seem to have been attempted on its part, which speaks badly for its protective sympathy and capabilities. To yourself, Mr Editor, and to the 'Dublin Quarterly Medical Journal,' are eminently due the best thanks of the Medical men engaged in the onerous and unceasingly responsible position of Asylum Superintendents, for your invaluable aid, as independent professional journalists, in sustaining them, for years past, so ably and perseveringly in the discharge of their high behests, and taking the deep interest you both have done in all matters affecting the best interests of the insane.

Now, Sir, for a few words on the "non-restraint system." In many of its phases that system may be set down as "a mockery, a delusion, and a snare;" but the *ignobile vulgus* was taken by it, and it became the popular cry and cant of the day, so that to say anything but in favour of it in all its impossibilities you necessarily became a marked man, and subject to abuse without measure. But even so, some few there were who did not flinch from exposing the cruelty and shortcomings of *the system* as it deserved. Your observations also in regard to "a Special Board of Examiners," for those seeking to be placed in medical charge of the insane generally, I conceive to be excellent and deserving of the best attention. Certainly this would be a more fitting and suitable line of procedure in order to procure the services of the most highly-qualified men, than by legislating for them, as if nothing but the sword of Damocles over their head in the grim vista of a cell in a county gaol, with or without "hard labour"—the very words of the new Act—would suffice to prevent them from "striking, wounding, ill-treating, or wilfully neglecting" their patients! In Ireland, as I stated in my former communication, no such legislation was deemed necessary to prevent the Medical Superintendent of its Asylum for Criminal Lunatics from acting after so impossible and insane a fashion; nor to the present time have we ever heard of any act of cruelty being perpetrated in it or any of its public Asylums, and I am yet to learn that the worthy and humane gentlemen who preside over the Asylums in England have ever so conducted themselves as to require this most degrading and most dishonouring penal legislation to have been enacted for their special behoof.

But, in conclusion, let me ask again, what excuse has "the Association of Medical Officers of Asylums and Hospitals for the Insane" to afford to their *confrères*, and the Profession at large, for this insulting and uncalled-for legislation having been accomplished without a single objection on its part?

I pause for a reply, from either its distinguished President, Dr Bucknill, or its able and energetic General Secretary, Dr Lockhart Robertson, or both. I am, &c. VIGIL.

September 27, 1860.

THE COMPOSITION OF CHLORODYNE.

To the Editor of the Medical Circular.

SIR,—My attention was called by Mr Davenport, the other day, to a reply in the Correspondents' column of the MEDICAL CIRCULAR, in which it is made to appear that there is only a slight difference, if any, between his Chlorodyne and that produced by Dr Ogden's receipt as given in a previous number of the CIRCULAR.

Mr Davenport showed me the difference, and gave me a bottle of each. I have since purchased a bottle of Ogden's, and compared it with Davenport's; and the difference is as strikingly manifest as in the sample he gave me, and which I showed to you, Davenport's being perfectly soluble, while the other falls to the bottom of the glass like quicksilver, and mixes about as readily. A difference is also clearly perceptible both in smell and taste.

The truth of this simple statement may be seen at my Office, 21 King William street, W.C., any day between two and five o'clock.

I am, &c.,

Oct. 2, 1860. C. J. HARRIS.

[Having seen specimens of the two preparations of Chlorodyne referred to in the foregoing note, it is but just to say that they materially differ in appearance, and also in their miscibility with water. Dr Ogden's Chlorodyne appears to contain a larger proportion of Chloroform than that prepared by Mr Davenport.—ED. MED. CIRCULAR.]

OUR NOTE BOOK.

THE SUN OPHTHALMOSCOPE.

Dr Macdonald, ophthalmic surgeon to the Demilt Dispensary of New York, says: "The use of sunlight instead of artificial light in ophthalmoscopy first suggested itself to me about a year ago, as a means of examining the patients attending the institution to which I am attached, and in which I had no facilities for examining by the ordinary method. The advantages which I have found it to possess are such that I now prefer to use it in my private practice. Of course, the plane or concave mirrors hitherto used could not be employed with sunlight, as its intensity would be too great; *convex* mirrors, however, by diverging the rays of light reflected from them, diminish its intensity, and the sun's rays reflected by such mirrors can be easily borne. Those that I employ are of glass, about 1 inch in diameter; have curves, one of 4, and one of 8 inches radius; and from their centres a disk of the silvering, about $\frac{1}{12}$ of an inch in diameter, is removed. With photophobic cases, the weakest mirror, *i.e.*, the one having the greatest curve, is used; in ordinary cases I use the other. The patient is seated in, and with his back to, the sun, and the surgeon proceeds as with the ordinary ophthalmoscope.

"Sunlight is much superior to other means of illumination; its intensity may be increased to any extent, and with it the fundus of the eyeball is seen of a more natural colour and appearance. By the use of convex mirrors, the field of the retina illuminated is much greater than when concave instruments are employed: for this reason, this instrument is much less difficult to use than others, and a tyro will distinguish all the points of interest in the retina at his first attempt. Dr W. Zehender, in the first volume of the 'Archiv für Ophthalmologie,' first proposed the use of convex mirrors, but only with artificial light."

In this country, especially perhaps in London, sunlight is too uncertain for us to think of its being commonly used; but I recollect that some years ago, in the case of a foreign body to be removed from the vitreous space, I availed myself of the sunlight for a final examination in the operating room: the sun was shining dimly through a fog, so that I could use the concave mirror we have for an ordinary lamplight examination without distressing the patient, and with very effective illumination for my inquiry. It may be worth consideration for sunlight ophthalmoscopists who prefer, or who happen to have the ordinary concave mirrors adapted for lamplight examinations, that the same should be used with sunlight, as it could be easily and well qualified, I suppose, by diminution of the too great illuminating power it had at any time. For this purpose, the patient might be seated with an upright screen attached to the high back of his chair, and thus would be protected from the heat of the sun; and on either side of the screen might be a shutter, to adjust, by sliding up and down to the height of the patient's head, with an aperture at which the sunlight would be admitted, and its extra power of illumination there reduced and regulated by one or more white curtains of crape or muslin.—J. F. S., in 'Ophthalmic Hospital Reports.'

VERATRUM VIRIDE IN PNEUMONIA.

In the 'Nashville Journal of Medicine and Surgery' for June, Dr A. A. Davidson has an article upon the use of veratrum viride in pneumonia. This is not new treatment, but his experience and confidence are such as to justify their repetition. He says, "I have followed no other particular treatment for the last two years in pneumonia and pleurisy than the medicine in question, and I am happy to say I have never seen a case terminate unfavourably under the treatment." In conclusion, he says, "I look upon the veratrum as being worth all the other treatments combined for pleurisy, pneumonia, and all the other diseases of an inflammatory nature, when carefully and judiciously administered. I speak this candidly, because it is my own experience that prompts me to do so."—'American Medical Monthly.'

ERECTILE TUMOURS.

In the 'Chicago Medical Journal' for June, Prof. Brainard has a lengthy and able article upon erectile tumours and their treatment. Some such tumours he has been treating successfully with the injection of a solution of the *lactate of iron*. We have not space for a synopsis of his paper, and will simply give his conclusions. He says, "The relative merits of the different methods of treating erectile tumours may be summed up as follows:—

"I. Excision should be performed in every case where the size and situation of the tumour will admit of its being performed. This is almost as much a rule in these cases as in cancer. The exceptions are the slight cases which may be trusted without treatment until they increase in size.

"II. When excision would cause too great a loss of substance, danger from hæmorrhage, or when, from any cause, excision is objected to, strangulation is to be preferred next in order; and whether affected with ligature alone, or with needles, or other means, it should always, if possible, embrace the whole diseased structure.

"III. In limited superficial nævi and erectile tumours, particularly if placed over bony surfaces, compression will often diminish, if not cure, the disease.

"IV. In deep-seated tumours, particularly aneurisms by anastomosis, cauterisation with the hot

(b) We have received the following letter from Miss M'Gowan, which is so interesting in an historical point of view, that we make no apology for its publication:

"16 Great Windmill street, March 22.

"SIR,—I hope you will excuse the liberty I take in troubling you; but seeing that you are publishing a sketch of Dr William Hunter, I think it may be interesting to yourself and readers to learn that the office at which the Journal in which you write is printed, is the house that was built and inhabited by the great man whose life you are illustrating; and that the room in which your article is being *composed* and *set up*, is the theatre in which he used to lecture and demonstrate to his pupils. My father purchased the house, nearly fifty years since, from Mr Wilson, a surgeon, whose wife was a Miss Cruickshank. At that time there was in the so-called garden a fig-tree planted by Dr Hunter. I have often heard my father regret that it was destroyed by some careless workmen: figs still formed on it when he bought the house. My father for a long time let the theatre for dissecting-rooms to medical lecturers, till the London University and other institutions superseded private schools.

"In 1848 we converted the theatre and that wing of the house into printing-offices: and, oddly enough, the printing has since then, if I may so express it, assumed a medical type.

"I am, Sir, yours respectfully,

"A. McGOWAN."

needles is an extremely efficient remedy, either by itself or in connection with other means.

"V. Setons or metallic needles may be used in the venous forms of the disease. They are more effectual when placed to some extent in sound tissue.

"VI. Ligature of the principal artery leading to the part is adapted to the variety called aneurism by anastomosis, the accidental thrilling variety, and particularly to that variety situated in the orbit of the eye. I believe, however, that it is more dangerous and less necessary than is generally supposed.

"VII. Vesicants, escharotics, and caustics are adapted to complete a cure, when a small portion of tissue remains after excision, strangulation, or seton. They are uncertain, and little to be relied on.

"VIII. A combination of several of these methods of treatment will often be found advisable."—'American Medical Monthly.'

PARISIAN MEDICAL INTELLIGENCE.

The Medical Profession will hear with regret of the definite retirement of M. Ricord from the post of Surgeon to the Hôpital du Midi. Philip Ricord is a native of America, and was born at Baltimore, on the 10th of December, 1800. Owing to the regulation now in force which excludes fron the exercise of hospital functions those surgeons who shall have attained the age of sixty, the term of service of the talented surgeon would naturally have expired at the end of the present year. M. Ricord has, therefore, probably deemed it a more dignified course to resign prior to the completion of the full period. For nearly thirty years this celebrated Professor has occupied the Clinical Chair of the special branch of Surgery to which the Hôpital du Midi is exclusively devoted. The materials with which M. Ricord has built up his colossal reputation have, for the most part, been gleaned from the wards of this establishment. The admiration he has won, the friendships he has secured, the fortune he has accumulated, are all more or less consequences of his connection with this hospital. It was not likely, therefore, with such associations crowding on the memories of the speaker and of his audience, that M. Ricord should be able to take leave of the field in which he had toiled so cheerfully and so indefatigably for the space of an entire generation without a lively feeling of emotion and regret, touchingly expressed by himself, and as warmly sympathized in by his hearers. The scene of last Thursday, M. Ricord's farewell to his hospital career, was a complete ovation. For more than two hours a numerous audience of friends, pupils, and admirers listened with deep interest and veneration to a most pathetic parting address. The speech of the talented surgeon embraced a masterly sketch of the many and valuable contributions—the fruits of a long life of well-directed industry—with which his labours have enriched the treasury of medical science. If any man at any moment of his life might be pardoned the indulgence of a little self-glorification, surely M. Ricord, on Thursday afternoon, was entitled to such a privilege. On this occasion, however, the modest and unassuming manner in which he alluded to his immense services charmed and delighted his hearers by its delicacy of feeling; and the deafening acclamations which succeeded his valedictory discourse bore ample testimony to the warm sympathy he enjoye amongst his professional brethren. The following are some of M. Ricord's more celebrated works:—'Mémoire sur l'Emploi du Spéculum dans les Maladies Vénériennes;' 'Memoire sur l'Inoculation Artificielle de la Vérole chez l'Homme.' (*vide* the 'Lancet,' 1838); 'Mémoire sur la Blennorrhagie chez la Femme;' 'Mémoire sur l'Emploi de l'Onguent Mercuriel dans le Traitement des Erysipèles;' 'Réfutation de l'Opinion de Hufeland sur la Blennorhagie;' 'Mémoire sur le Chancre;' 'Mémoire sur l'Epididymité;' 'Traité Pratique des Maladies Vénériennes, et Recherches sur l'Inoculation appliquée à l'Etude de ces Maladies' (this, perhaps, is M. Ricord's principal work); 'Du Sarcocéle Syphilitique, de l'Induration des Corps Caverneux, et d'une Altération semblable de la Coque Fibreuse de l'Œil;' 'Différence entre la Blennorrhagie et le Chancre;' 'Clinique Iconographique de l'Hôpital des Vénériens;' and the 'Lettres sur la Syphilis,' originally published in the 'Union Médicale,' and now embodied in a volnme. The vacancy at the Hôpital du Midi is likely to be filled by a gentleman who has already distinguished himself in the syphilitic specialty, as well as in general surgery—M. Alphonse Guérin.

I read to-day, in 'The Times,' a letter from Naples, in which the brave Garibaldians are spoken of as "already suffering much from fever." I trust that your appeal to the medical public for quinine may have been responded to, for the whole of the country now occupied by the heroic champions of Italian freedom, and more especially that district which lies seawards of Capua, and near the mouth of the Volturno, from the middle of September till the middle of November, plentifully exhales the most deadly malaria. Let us not forget the ill-fated expedition of Walcheren, and let us use strenuous efforts to avert a similar fate from the army of patriots now investing Capua.

At the late meeting of the Society of Practical Medicine, a subject in which the English medical public must naturally be interested formed the theme of discussion. M. Coursserant, after reminding the Society of the difficulties and ill-success attending the treatment of most of the organic changes in the structure of the eye, introduced to their notice the particulars of a case of hydrophthalmia, in which the plan of treatment originated by Mr Hancock had been adopted and followed by excellent results. M. Coursserant said that he agreed with Mr Hancock in believing that the excessive outpouring of fluid in the eye, and its over-distension, might be in some way connected with a too energetic and too permanent contraction of the tensor of the choroid, and, therefore, decided upon effecting the complete division of this muscle in the way recommended by the talented London surgeon. As hydrophthalmia existed in both eyes, and was furthermore congenital, the operation was undertaken as a sort of forlorn hope, and with no very sanguine expectation of success. The globe of the eye had attained on either side a volume double that of the normal state, and the amount of vision was nominal only, and utterly insufficient for the purposes of locomotion. The disease completely resisted all attempts at treatment, *one of the means resorted to being paracentesis of the anterior chamber*, performed every fortnight during the space of five months. A fortnight after the performance of Mr Hancock's operation, the patient, a child eight years of age, was able to run about and play with his schoolfellows, the eyesight being inconceivably improved, and the volume of the globe considerably diminished. The testimony of M. Coursserant, added to the already-expressed approbation of M. Desmarres, who has tried the operation in glaucoma, will, I trust, prove a sufficient answer to those gentlemen who have hitherto chosen to shut their eyes to the value of Mr Hancock's method, and who, in their *blind* attachment to iridectomy, have thought fit to condemn, and apparently without trial, a surgical novelty which, in other hands, has yielded, and still does yield, most excellent results.

Whilst on the subject of eyes, I may mention that M. Desmarres possesses at present, at his clinique, a patient with a cysticercus imbedded in the vitreous humour. As the body of the parasite is lodged exactly in the axis of vision, sight is almost lost. Nevertheless, M. Desmarres, warned by M. de Graefe's ill success, declines to interfere; and he is right.

I must not omit to inform you of the purport of a note read at the last sitting of the Academy of Sciences by M. Baillarger, one of our celebrated "alienists" (as the mad doctors stylo themselves), and also one of the physicians of the Salpêtrière. The subject of the communication was, Hypochondriacal Melancholy being one of the most certain and reliable Symptoms precursory of General Paralysis. The Author, in addition to his position at the Salpêtrière, possesses, in an extensive private practice, a large field for the study of mental derangements, and this particular class has specially claimed his attention. All medical men who have given the matter any consideration are agreed in considering this fearful malady (general paralysis) as most insidious in its outset, as being slow and gradual in its development, and as possessing few appreciable preliminary indications, and none, generally speaking, of a character sufficiently distinct and unequivocal to be considered as premonitory of its approach. This distinctive character M. Baillarger claims for the symptom of hypochondriacal melancholy. "The distorted conceptions," says this physician, "of those labouring under hypochondriacal melancholy are, it is true, most varied and capricious; there are, however, certain elements of similitude which act as guides in the recognition of the symptom. One of these is the systematic obstinacy evinced by the patient in himself producing the disturbance of function of which he complains. One man, for example, imagines himself dumb, and resolutely keeps his mouth closed; another, that he is blind, and in the same way refuses to open his eyes; and so on. In all the cases thus primarily affected with these distorted conceptions, and which M. Baillarger has been able to follow up, general paralysis has sooner or later been found to occur with unvarying regularity. The same physician furnishes some facts based on statistics which are not without interest. He has ascertained that general paralysis is met with in the males of all classes of society with an equal frequency; whereas the females of the higher walks of life enjoy a comparative immunity from this form of insanity—an immunity not experienced by females of humbler status.

M. Chatin, one of the participators in the debates at the Academy of Medicine on iodism at the beginning of the year, criticized some of the experiments by which Signor de Luca, Professor of Chemistry at Pisa, has endeavoured to show that the rain-water which falls in that city does not contain iodine. He informed the Academy of Sciences that he (M. Chatin) had not only found that element in the rain-water of Pisa, but also in that of Florence and Lucca, although certainly in smaller proportions than at Paris. He further stated, in reply to the objections made to his tests, that he had found iodine both in distilled water and in potassium taken at the best laboratories, and apparently perfectly pure. He admitted that he was unable to obtain the iodine in its natural state from the water which contained it; but, on the other hand, he announced that he had extracted it from two aquatic plants—namely, the Nasturtium officinale, and the Ceratophyllum demersum; a fact which showed that the water in which they grew must have contained some of this element.—'Lancet.'

UNIVERSITY OF ST ANDREWS.

MEDICAL EXAMINATION PAPERS.

SEPTEMBER, 1860.

FIRST EXAMINATION.—FIRST PART.

TO BE TRANSLATED INTO ENGLISH.

Cognitis indiciis, quæ nos vel spe consolentur, vel metu terreant, ad curationes morborum transeundum est. Ex his quædam communes sunt, quædam propriæ: communes, quæ pluribus morbis opitulantur: propriæ, quæ singulis. Ante de communibus dicam: ex quibus tamen quædam non ægros solum, sed sanos quoque sustinent; quædam in adversa tantum valetudine adhibentur. Omne vero auxilium corporis, aut demit aliquam materiam, aut adjicit, aut evocat, aut reprimit, aut refrigerat, aut calefacit; simulque aut durat, aut mollit. Quædam non uno modo tantum, sed etiam duobus inter se non contrariis adjuvant. Demitur materia, sanguinis detractione, cucurbitula, dejectione, vomitu, frictione, gestatione, omnique exercitatione corporis, abstinentia, sudore. De quibus protinus dicam.

Give the origins or primary meanings of the following words: Astragalus, Blastema, Condyle, Cysticercus, Hemiplegia, Lithotrity, Peroneal, and Scaphoid.

SECOND PART.

Chemistry.—1. Water boils at 212° F. and freezes at 32° F. Is this statement universally true, or only true under certain conditions? What are the corresponding boiling and freezing points in the Centigrade Thermometer? Explain the method of converting degrees from one of these scales to the other. Reduce 100° F. to the Centigrade Scale and 256° C. to the Fahrenheit Scale. In the Arctic Regions would you prefer mercurial or spirit thermometers?

2. What compounds does oxygen form with carbon, hydrogen, sulphur and phosphorus, and what are their respective formulæ?

3. Write down the formulæ expressing the composition of nitre, borax, alum, and corrosive sublimate, and explain the method of obtaining any two of these substances in a state of purity.

THIRD PART.

Materia Medica and Therapeutics.—1. Name the principal medicines which are commonly regarded as diuretics, and describe the modes in which they respectively act. Do these substances increase the aqueous portion or the solid constituents of the urine, or both? What effect upon the solid constituents of the urine is produced by copious water-drinking?

2. Are you acquainted with any substances which have the power of checking the general metamorphosis or disintegration of the tissues? If so, describe them; and explain their mode of action, and the cases in which their administration may be of service.

3. Quinine is sometimes adulterated with one or more of the following substances: gypsum, chalk, boracic acid, sugar, starch, and salicine. How would you detect these impurities?

Supposing that any other acid had been mixed with hydrocyanic acid, how would you detect the adulteration?

How would you determine the strength of any given specimen of hydrocyanic acid?

4. What is the preparation of bismuth that is commonly used in medicine? How is it prepared? What are its uses? Describe the symptoms which would lead you to prescribe it, and write a Latin prescription (without symbols or abbreviations) for a draught containing it.

SECOND EXAMINATION.

Anatomy and Physiology.—1. Describe the muscles which flex the leg upon the thigh.

2. What parts must be removed to expose the pterygoid muscles? Describe these muscles, noticing their relations to adjacent structures, the source from whence they derive their nerves, and their actions.

3. Describe the boundaries and contents of the axilla.

(N.B. Candidates who prefer answering this question fully may neglect the two preceding questions.)

4. What are the respective numbers of the temporary and the permanent teeth? State, as nearly as you can, the period at which you would expect the different teeth to appear. Describe the structures which occur in the composition of a tooth. If you have studied comparative anatomy, you may describe the peculiarities of dentition in the ruminants and in the rodents.

5. Describe the appearance and structure of the villi, and explain the part which they are supposed to take in the process of intestinal absorption.

6. What are the different refracting media of the eye through which the rays of light must pass before they reach the retina? Explain how these different media modify the direction of the rays. What are the conditions giving rise to myopia and presbyopia? Explain the way in which glasses remedy these defects.

THIRD EXAMINATION.

N.B. In answering the practical questions, the examiners require every candidate to specify the mode of treatment which he is in the habit of adopting, and the doses of the medicines which he prescribes.

Medicine.—1. State what you know of the general doctrines of the hæmorrhagic affections, especially as to their origin, causes, nature, and varieties; and name the special hæmorrhagic affections.

2. Describe the general principles applicable in the detection of valvular disease of the heart, the diseases to which the valves of that organ are liable, and the means of detecting the particular valves affected, and the nature of the affection.

3. What advantages are gained by a selection of climate for invalids, what affections are likely to be benefited by such selection, and what climates would you select, 1st, for incipient phthisis—2nd, for chronic bronchitis, in this country and abroad?

4. What are the different forms of lithiasis, and what treatment would you adopt in each?

5. A robust young man was seized four days ago with headache and shivering. He went to bed and slept well all night, but on the following morning was seized with pain (severe and stabbing) below right nipple; his pulse then became rapid and skin hot. At the period of observation pulse 108, skin pungently hot, tongue covered with a thick white fur, rubbing sound with fine crepitation below right nipple.

What disease does the patient labour under? What would your prognosis be? How would you treat such a case?

6. A patient æt. 50 is losing flesh and weight rapidly, subject to headache and palpitation; appetite voracious; urine plentiful, sp. grav. 1·040; sample of urine turned claret colour by liquor potassæ.

What is the disease, and how would you treat it?

FOURTH EXAMINATION.

Surgery.—1. What is iritis? What are its symptoms and diagnostic marks, the results if it proceeds unchecked, and the treatment?

2. What is hydrocele? Mention its varieties. With what other tumours of the scrotum might it be confounded, and state how it may be distinguished from them?

3. Describe the various forms of dislocation of the hip-joint.

4. Describe the process of formation of an aneurism. Mention the methods of treatment.

5. A man falls from a height on the top of his head, and is taken up insensible. On examination, no depression or other sign of fracture is found on the surface of the cranium. His breathing is laboured and his eye is insensible to light. He remains unconscious, and his urine and fæces are passed involuntarily. At first blood, then watery fluid flows from the ear. Ultimately he dies comatose.

What injury has been received? Explain how it has been produced, account for some of the most prominent symptoms.

What appearances will probably be found on post-mortem examination?

FIFTH EXAMINATION.

Midwifery.—1. Mention the various circumstances which may make it proper to induce premature labour; and describe the different ways in which this may be effected, stating which you would prefer, and why so.

2. Recount the symptoms and signs of pregnancy, stating the circumstances which may in particular cases obscure the diagnosis.

3. What are the points in the history, the symptoms, and the physical signs of a case, which enable us to distinguish ovarian dropsy from ascites?

4. A woman, on the day after a very severe labour, in which turning had to be performed, had a rigor, which recurred from time to time during the next week, being always followed by perspiration, and accompanied by gradually-increasing asthenic fever. Her pulse was extremely rapid and feeble, her tongue dry and brown, her skin of a dusky yellowish colour; the lochia were fœtid, and the milk suppressed. She became very restless and sleepless, and died before the end of the fortnight, the region of the uterus having been only slightly tender on pressure. What was the nature of her disease, what the morbid appearances to be expected in the dead body, and what treatment ought to have been employed?

PUBLIC HEALTH.—By the Public Health Act of 1858, the Privy Council are empowered to cause inquiry to be made, when they see fit, in relation to the public health in any place; and a Medical officer, Mr Simon, is attached to the Council, and superintends such investigations. His report of the proceedings of 1859, which has recently been issued, deals with several subjects of great interest. Among them is that which has still to be called "the Thames nuisance." In a paper communicated by Mr. Ord, that gentleman describes the symptoms of a poisoning of the nervous system which occurred very generally in the summer of 1858 among persons employed upon the river, and observes that in 1859, when extensive disinfecting operations were carried on at the mouths of sewers, the sulphuretted hydrogen gas was not in proportion sufficient to the production of the symptoms; and he remarks, that if the emanations of a river in so foul a state do not actually originate disease, and, on the other hand, percolations from cesspools into the soil and wells is proved to be highly injurious, then even this stage in the process of purifying London must be accepted as an improvement upon its prevous condition. The putrefactive matter, instead of abiding in a thousand places as a focus of disease, is brought into one large aggregate, where it may be more readily submitted to disinfecting processes, and where it finds in the water of the receiving stream elements which appear to disarm it of much of its destructive influence. Happily this source of disease is destind in a very few years to a much more complete banishment.

Births, Marriages, and Deaths.

BIRTHS.

HOGG.—September 11, at Bedford square, the wife of Jabez Hogg, Esq., M.R.C.S., of a son.

MACKAY.—September 6, at the Royal Naval Hospital, Plymouth, the wife of Staff-Surgeon George Mackay, M.D., of a son.

MOFFATT.—September 25, at Thornhall, Balmout, the wife of Robert Moffatt, M.D., of a son.

O'REILLY.—September 5, at Bishop's Stortford, the wife of Michael O'Reilly, M.D., of a son.

ROWLAND.—September 24, at Bootle, near Liverpool, the wife of Henry M. Rowland, Esq., M.R.C.S., of a daughter.

SYMES.—September 22, at Forston House, Dorchester, the wife of J. Gustavus Symes, Esq., M.R.C.S., Medical Superintendent of the Dorset County Asylum, of a son.

MARRIAGES.

CHAVASSE—COGHILL.—September 19, at Castle Townsend, William Izon, only son of Pye Henry Chavasse, Esq., F.R.C.S., of Priory House, Birmingham, to Anna Georgina, daughter of the late Vice-Admiral Sir Josiah Coghill Coghill, Bart., of Belvedere, Co. Dublin.

EMPSON—RHODES.—September 6, at the Parish Church, Market Rasen, Charles Frederick Empson, Esq., M.R.C.S., of Selby, to Alice, youngest daughter of Thomas Rhodes, Esq., of Market Rasen.

MORGAN—PATERSON.—July 5, at St James's Church, Sydney, C. W. Morgan, Esq., M.R.C.S. Eng., of Newcastle, N.S.W., to Jessie, only daughter of the late J. Paterson, Esq., Captain H.E.I.C.S.

SMITH—HAIGH.—September 26, at Leeds Old Church, William Josiah Smith, Esq., M.R.C.S., to Theresa Haigh, of Newley, near Leeds.

DEATHS.

BEST.—September 23, at Thetford, Marian Eliza, daughter of Henry W. Best, Esq., M.R.C.S., aged 8 years.

BYRNE.—September 6, at Fort Moultrie, Bernard M. Byrne, M.D., Surgeon in the United States Army, of typhoid fever, aged 47. He was a native of Ireland, and emigrated, while quite young, with his parents, to Baltimore, and graduated at the University of Maryland. He was subsequently engaged as Prosecutor to the Professor of Anatomy in Washington College, New York; and afterwards, about 1836, entered the Medical Staff of the Army, serving with great credit through the Florida and Mexican wars. He then served as Medical Director-General on the Pacific coast. He was an accomplished writer, and his Treatise on Cholera was officially approved by the United States Government, and is now used as a text-book in the Medical Department of the British Army. He married the daughter of Colonel Abert, chief of the Topographical Engineers, Washington, and has left a widow and three children.

CRELLIN.—October 1, at Forest hill, Sydenham, Frederick Crellin, F.R.C.S. and M.R.C.S. Eng., L.S.A. Lond., Surgeon R.N., aged 59.

FINNEY.—September 24, at Newburn, Northumberland, Dr Thomas Finney, aged 65.

HOLT.—September 29, at Enfield, Middlesex, William Henry Holt, M.D., M.R.C.S. Eng. 1802, aged 77.

HOWARD.—September 15, at Mornington road, Regent's park, William Lucy Howard, M.D., aged 38.

MACAULAY.—July 15, at Odin Bay, China, on board the hospital ship 'Mauritius,' of dysentery, Robert Welbank Macaulay, Surgeon, Bengal Medical Service, youngest son of Dr Alexander Macaulay, of Edinburgh, aged 37.

TOLDERVY.—September 4, suddenly, the result of an accident, James Bailey Toldervy, M.D., of Fredericton, New Brunswick, aged 52.

LONDON HOSPITALS.—Count Karsakoff having been deputed by the Emperor of Russia, to whom he acts as Aide-de-Camp, to make inquiries as to the management of the finances and establishments of the various hospitals and charities of London, has expressed in the public journals his thanks for the full information courteously accorded to him.

MEDICAL NEWS.

Royal College of Physicians.—At the ordinary quarterly Comitia, held on Tuesday, the 2nd inst., the following gentleman, having undergone the necessary examination, was admitted a Member of the College:—James Price, M.D., Brixton. The following gentleman was also admitted a Member of the College, having been previously elected under the temporary bye-laws, now expired:—Edward Langdon Bryan, M.D., Brighton.

Apothecaries' Hall.—The following gentlemen passed their examination in the science and practice of Medicine, and received certificates to practise, on September 27th, 1860:—George Barker, Totteridge, Herts; William Joseph Callon, Liverpool; Richard Davy, Chulmleigh, North Devon; William Frederick Ryall, Plymouth; Henry William Williamson. The following gentlemen also on the same day passed their first examination:—Robert Cotterill Garner, Stoke, Staffordshire; John Valentine Laverick, Winderwell, Yorkshire. As an Assistant:—Robert Downes, London.

University of St Andrews.—List of Gentlemen on whom the degree of Doctor of Medicine was conferred, 28th September, 1860:—James Veitch Adam, L.R.C.S. Ed., Wooler; John Baxter, L.R.C.S. Ed., New Brunswick; Samuel Dougan Bird, M.R.C.S. and L.A.C., Richmond, Surrey; Charles Henry Bennett, L.A.C., Hammersmith; Charles Corbett Blades, M.R.C.S. and L.A.C., London; Robert Harrison Bowness, L.R.C.P. Ed. (by exam.), Lancashire; William Braithwaite, M.R.C.S. and L.A.C., Leeds; Alfred Frederick S. Clarke, L.A.C., Manchester; James Edmund Dawson, M.R.C.S. and L.A.C., Liverpool; George Downs, F.R.C.S., Stockport; Wm. Louis Dudley, M.R.C.S and L.A.C., Dudley, Worcestershire; William Edger, M.R.C.S. and L.A.C., Nether-Stowey, Somerset; William Galgey, Belfast; William Goldie, L.R.C.S. Ed., Lanarkshire; Octavius Charles Harvey, M.R.C.S., Jamaica; Nathaniel John Haydon, M.R.C.S. and L.A.C., L.R.C.P. Ed. (by exam.), Bovey-Tracey, Devon; Edmund John Hoskins, M.R.C.S. and L.A.C., H.M. Indian Service; John Hughlings Jackson, M.R.C.S., Green-Hamerton, Yorkshire; Harry Pike Major, M.R.C.S. and L.A.C., Hungerford, Berks; Edward Hooper May, F.R.C.S. and L.A.C., Tottenham, Middlesex; Richard Metcalfe, M.R.C.S., Hawes, Wensleydale, Yorkshire; James Part, F.R.C.S. and L.A.C., London; Geoffrey Pearl, M.R.C.S. and L.A.C., Windsor; Robert S. Peart, M.R.C.S. and L.A.C., Tynemouth, Northumberland; Thelwell Pike, M.R.C.S. and L.A.C., Weyhill, Hants; Senjee Pulney Andy, Madras; George Ross, M.R.C.S. and L.A.C., L.R.C.P. Edin. (by exam.), London; Charles Royston, M.R.C.S., L.A.C., L.R.C.P. Ed., London; Edmund Shaw, M.R.C.S. and L.A.C., Trinidad; William Stanfield, M.R.C.S. and L.R.C.P. Ed., Oldham; Henry C. Stevenson, L.R.C.S. Ed., N. Brunswick, B.N.A.; Daniel Robert Thompson, Madras; John H. Tylecote, L.R.C.S. Ed. and L.A.C., Heywood, Staffordshire; Robert George Watts, M.R.C.S. and L.A.C., Clifton, Bristol; John Williams, M.R.C.S. and L.A.C., Doncaster; John Williams, M.R.C.S., Brecon.—The Degree of Bachelor of Medicine was also conferred on John Robinson, B.A. St Andrew's, Runcorn, Cheshire.

Royal College of Surgeons.—The Library and Museum of this institution are re-opened.

Cambridge University.—The examinations for medical degrees in the ensuing term at Cambridge will commence on Monday, the 12th of November, at nine a.m., in the Arts School.

Radcliffe Infirmary, Oxford.—The Governors have received the sum of 164*l.* from the Duke of Marlborough towards the support of the above institution. The money is part of the proceeds arising from the fees paid by visitors to the palace and gardens at Blenheim, the whole of which is generously devoted by his Grace to kindred philanthropic objects.

Melville Hospital.—On a recent visit to this establishment by Miss Nightingale, that lady pronounced the Melville Hospital to be in every respect the best of the Naval or Military Hospitals in this kingdom. Before leaving Melville, the First Lord of the Admiralty intimated to the principal Medical Officer his satisfaction at the result of the inspection.

The Cholera.—By an order of the Board of Health, of Sept. 14th, Tangier is considered as suspected of cholera morbus, and the other ports of Morocco continue to be classed as infected.

Surgeons Not Wanted.—The Manchester guardians have decided upon reducing the number of relief and medical districts from seven to five, in consequence of the decrease of pauperism. Two of the surgeons have resigned, and it is not intended that the vacancies shall be filled up.

The Prisons of Naples.—It is reported (credat Judæus Apella!) that one of the decrees issued by the new Government in Naples appoints a commission of advocates—not one medical man—for the improvement of the sanitary condition of the prisons. Have not long years of Bourbonism left bad laws enough to occupy the reforming energies of the Italian bar?

The Health of the Miner.—Recent deductions from tables, showing the duration of the life of the miner, prove that at the age of 20, miners experience an average of 46 per cent. of sickness more than the general class; at the age of 30, they show 70 per cent.; at 40 years, 78 per cent.; at 50 years, 76 per cent; and at 60 years, 53 per cent. more than the ordinary class of lives. It has been ascertained that in Cornwall 61 per cent. of the miners die of diseases of the chest, and only 31 per cent. of the rest of the population.

Effect of Music on the Sick.—The effect of music upon the sick has been scarcely at all noticed. In fact, its expensiveness, as it is now, makes any general application of it out of the question. I will only remark here, that wind instruments, including the human voice, and stringed instruments, capable of continuous sound, have generally a beneficial effect—while the pianoforte, with such instruments as have no continuity of sound, have just the reverse. The finest pianoforte-playing will damage the sick, while an air like "Home, sweet Home," or "Assisa al pié d'un salice," on the most ordinary grinding-organ, will sensibly soothe them—and this quite independent of association.—*Florence Nightingale.*

Dr Rufz, Director of the Garden of Acclimatization, established at Boulogne, has presented to the Academy numerous parasites found in foreign animals:—a leech found in the throat of a black stork; a tænia in the intestines of an ostrich (an animal which, according to Buffon, was free from parasites, &c.)

Liverpool Infirmary School of Medicine.—This school was opened on Monday by an excellent address from Dr Gee. At the close of the lecture the chairman briefly addressed the students, congratulating them on the choice they had made of a Profession, and urging them by their good conduct to uphold the character of the institution. He then proceeded to distribute the prizes awarded during the past session. The first prize was a gold medal, awarded after an examination in every subject taught in the school, and to the possession of which is attached the privilege of residence for a certain period in the Royal Infirmary. This prize was gained by Mr Jasper Capper, who had obtained a larger number of marks in almost every department than had ever been obtained before. The other prizes were as follows:—Surgery—(Lecturer, Mr Long): Silver Medal, Mr Capper; Certificates, Mr Ricketts and Mr Sheldon. Medicine—(Lecturer, Dr Inman): Book prize (equal), Mr Thoruburn and John K. Kenyon. Anatomy and Physiology (Senior Class)—(Lecturer, Mr Fletcher): Medal, Mr Capper; Certificates, Mr Ricketts and Mr Thornburn. Anatomy and Physiology (Junior Class)—(Lecturer, Dr Waters): Medal, M. G. B. V. Nash; Certificates, George S. Kenyon and Mr Jackson. Chemistry—(Lecturer, Dr Edwards): Medal, Mr Thomas Bird; Certificate, Mr Johnstone. Midwifery—(Lecturers, Mr Batty and Dr Grimsdale): Medal, Mr George S. Kenyon; Certificate, John K. Kenyon. Materia Medica—(Lecturer, Dr Nevins): Medal, Mr George S. Kenyon; Certificate, John K. Kenyon. Botany—(Lecturer, Dr Collingwood): Book Prize, Mr R. Lupton; Book Prize for Collection of Plants, Mr Isaac Thompson; Certificate of Honour for ditto, Mr William Cross. Practical Chemistry—(Lecturer, Dr Edwards): Book Prize, Mr John Eaton.

Scottish Lunatic Asylums.—The District Lunacy Boards of Fife, Perth, and Argyle, after suspending operations in the expectation of an amendment of the law, have, it is understood, again resolved to proceed with the erection of local asylums. Although the Scottish Act was passed three years ago, the Boards have delayed action until the present time, seeking the aid of the Legislature in various matters connected with the size of the districts, mode of assessment, and machinery for the committal of the insane to custody. This delay is to be regretted in the interest of the patients, many of whose disorders have thus had time to become chronic and confirmed. In Fife and Argyle, accommodation will be required for about 200 inmates for each of these districts. Beautiful sites are said to have been secured, and the works to be in progress. The Perthshire Board have also purchased about sixty acres of ground for about 2500*l.* to receive a similar number. Inverness has secured a good site, and will probably be joined by Caithness. It is thought that Orkney and Shetland, from their great steam intercourse with the Lothians, will join some of the establishments near Edinburgh.

Garibaldi's Sick and Wounded.—"I am sure that any information connected with the Military Hospitals of Naples and Sicily will be read with interest by my benevolent countrywomen. From Sicily, then, the news is bad. Pernian fever has made its appearance in Barcelona, and four of the Genoese Carbineers have fallen victims. All the patients are therefore to be removed to Palermo, where Miss Middleton has already given, and may yet give, invaluable services. A Central Hospital is to be formed in Naples. I am requested to announce the receipt of a large number of cotton sheets, bearing the address of 'Campbell, London,' and part of them I have seen. I am also requested to ask who sent fifteen cases of instruments, and what has become of them, as they have not turned up. They would have been invaluable in Sicily."—'Times.'

Sir Benjamin Brodie, Bart.—It affords us much gratification to state that, notwithstanding the failure of the operation of which this distinguished surgeon was lately the subject, the worthy baronet is sufficiently well to walk out without a guide, and that he is now at a watering place on the south coast, with a view to obtain a complete restoration of his health.

The Army Medical Service.—The great improvement which has been made in the pay and position of the Medical Officers of the Army appears to have had the effect of attracting a large number of candidates to that branch of the public service; and we understand the applicants are so numerous as to enable the authorities to give the preference to those gentlemen who possess a diploma in Surgery and a degree in Medicine, over those who hold merely a *licence* to practise Medicine and Surgery. We recommend, therefore, all aspirants for the Army Medical Department so to conduct their studies as to enable them hereafter to obtain from the bodies legally entitled to grant such in this country, diplomas in Surgery and degrees in Medicine, and not content themselves with educating for the pass examinations required by those bodies which grant *licences* only.

A Village of Arsenic-eaters (?)—A stream called Whitbeck, rising in the Blackcombe Mountains, in West Cumberland, contains arsenic in determinable quantity. The arsenic is most probably derived from veins of arsenical cobalt ore, through which it percolates; for a few yards above the source of the stream there is the entrance of a mine, which is very rich in arsenical ore. The arsenical water is habitually used for every purpose by the inhabitants of the little village of Whitbeck, and with beneficial results so apparent that one might be justified in paradoxically characterising it as a very wholesome poison, the deadly elements in dilution being productive of the most sanitary effects! Ducks will not live if confined to the Whitbeck; and while trout abound in all the neighbouring rivulets, no fins are ever found in the arsenicated stream. But its use by the villagers does not give rise to any symptoms of arsenical poisoning, but rather to the effects which are observed in Styria among the arsenic-eaters there. When the railway was being carried past Whitbeck, the first use of the water produced the usual marked effects on the throats both of the men and horses employed on the works. The soreness of mouth from which they at first suffered, soon, however, disappeared, and the horses gave rise to that sleekness of coat assigned as one of the effects produced by the administration of minute but repeated doses of arsenic. It is a question how far the rosy looks of the Whitbeck children, and the old age which a large proportion of the inhabitants of the village attain, are to be attributed to the arsenic present in the water.—'Westmoreland Gazette.'

NATURAL ATTEMPT OF CURE OF TUBERCULAR PHTHISIS.

DISEASE RENEWED BY AN ATTACK OF CONFLUENT SMALL-POX — DEATH FROM HÆMORRHAGE—POST-MORTEM APPEARANCES.

By JOHN GASON, M.D., A.B., &c.,
Practising Physician at Rome.

I now come to a case equally interesting to the physician, though unfortunately terminating unfavourably. However, the result of the post-mortem examination proves the truth of what many unprejudiced physicians of the present day are fully convinced of—that phthisis is curable. I shall make some remarks on both cases in conclusion.

Dr B., æt. twenty-eight years, married, of a nervo-sanguineous temperament, and very irritable, had for several years past frequent attacks of spitting of blood, cough attended with considerable expectoration, night sweats, and all the signs and symptoms of tubercular phthisis. He had been under the care of the late Dr Pritchard, in England, who recommended him to go to Italy, where he improved very much in health. In January 1849, he was attacked with confluent variola. He had been vaccinated when a child. The attack was a very severe one: the eruption completely covered the palate of the mouth, fauces, and conjunctiva; but it proceeded regularly, and he had but slight secondary fever. He had much cough during the attack, but he recovered rapidly. During the summer of 1849 he continued tolerably well, except that he had more cough than usual, which had never quite ceased, but gave him very little annoyance, and was attended with little expectoration. He complained more than usual of difficulty in walking up stairs; he regained his strength, however, and felt better for a change to the neighbourhood of the sea. During the winter of 1850 he began to feel pain in his chest, and had more difficulty of breathing; his cough was more troublesome, and there was more expectoration; but he had no hectic symptoms, and his appetite was good, and he thought himself improving in health, when, in the month of March 1851, he was suddenly seized with spitting of blood to a considerable amount, which, however, stopped soon, but returned at times for the next ten days, when he began to feel his strength rapidly giving way, and his breathing becoming more oppressed, so as not to allow of his lying down in bed. He gradually sank, and died on the 31st March, 1581.

Post-mortem Examination.—The external appearance of the chest was very much distorted; the right side projected very much, forming what is called chicken-breast. The left side was very flat, and smaller than the right side. On opening the chest, by dividing the cartilages of the ribs, and raising the sternum, I found the mediastinum drawn very much to the right side. The left side of the thorax was much smaller than the right, particularly in the superior third, where the ribs were very much flattened. The pericardium and its contents occupied almost exclusively the lower portion. Very strong and old adhesions connected together the pleura of this side, as well as the lobes of the lung. The left lung was much hepatised, except in the inferior third, which was slightly emphysematous, with hard tubercles scattered throughout this portion. The lung was not half the size of the right. Its external surface was of a dirty white colour, and in various spots appeared raised, which, on being cut into, were found to be cavities whose external walls were very thin, and formed of thickened pleura. Into some of these a large bronchial tube opened, while others were formed only of ruptured tubes. These were mostly on the anterior surface. When the cavities were washed, the walls were of a white colour. The superior and external surface of this lung was dark, friable, and contained several small abscesses. There were also eight or ten small shut cavities in different parts of this lung, lined by a thick membrane, and containing a little colourless fluid. Some of these cavities were about the size and shape of a kidney bean, while others were round. The right lung was of a dark red colour, externally mottled with purple spots in size that of a split pea. On opening this lung, from the trachea downwards, I found the mucous membrane much inflamed, and thickened throughout its whole extent. In the superior and external third of this lung, there was a dark portion in size about that of a walnut. In the middle of this was an ulcer, and in the centre of the ulcer an artery, about the size of a small crow-quill, partially divided, and entangled in what appeared to be cellular membrane. This had been evidently the seat of an effusion of blood. There were several small ulcers in different parts of this lung, as well as several cartilaginous tubercles. The right lung was in the most part healthy, except in the upper third, as before mentioned, and in its inferior edge, in which there were five or six hard tubercles. The bronchial tubes were much increased in thickness. Adhering to this lung, and posterior to the bifurcation of the trachea, were five hard glands, the size of kidney beans. On opening the pericardium, I found in it more than six ounces of a clear, amber-coloured fluid. The heart was increased in size, the walls of the right ventricle were thin, the auricles much engorged with a quantity of very dark grumous blood, and in the ventricles were large masses of sanguineous concretions free from the colour of blood. All the abdominal viscera were healthy.

Is pulmonary phthisis curable? This is an interesting question for the practical physician, and is probably that which he generally puts to himself when called to see a patient labouring under this disease. Some years since it would probably have been answered in the negative; but now few, if any, physicians can pass many years in practice without being able to record cases of recovery. The statement made by Andral, in his 'Clinique Médicale,' appears to me untenable,—"that though tuberculous cavities may cicatrise, still, that in the great majority of cases this cicatrisation is scarcely of any use to the patient, in consequence of the simultaneous existence of a great number of other tubercles, and that the obliteration of a cavity can only be advantageous in the case where there was but one tubercle." On the contrary, I have frequently witnessed persons recover whose cases presented as evident signs of tubercular phthisis as did either of the above-mentioned. Neither can I agree with Laennec, that it is impossible to cure phthisis in the first stage. The case of Dr B. clearly manifested tubercles in their various stages, some of which had ceased to possess any vital action. We frequently see cases of consumption progressing favourably—the attendant fever subsiding, the expectoration diminishing, and the functions re-assuming a healthy action,—when the patient is attacked by some disease—such as small-pox, measles, influenza, and the like—and the disease, which had been dying out, is again set up. We must look on these cases, however, as accidental, which may be avoided under certain circumstances, and unconnected with the disease itself. I believe that if taken at an early date, and treated with due regard to its signs and symptoms, phthisis may, in very many cases, be arrested, and the constitution at the same time so much improved as to allow of its removal altogether from the system.

We daily see cases recorded as being cured by such-and-such a remedy. Why should we close our ears entirely to their truth, because the same result is not found to follow in cases which we may have the care of? The reason appears to me to be very plain—that, having a preconceived idea of the hopelessness of the disease, medical men have recourse to one universal treatment for a disease which may depend on very widely different causes.

For my own part, I have been long convinced that the cure of phthisis is generally ascribable—1st, to the removal of the irritation which so frequently accompanies the formation of tubercle; 2ndly, to the replacing in the economy of some element which it may have been deprived of, which is necessary for the prevention of the deposition of tubercle, or for its elimination from the system; and, lastly, to the supplying of the system with suitable nutriment. The two cases which I have given show some of the very interesting means which Nature adopts to rid herself of this disease; and I would class them as resolution, and ulceration, and cicatrization. And here all the endeavours of the physician should be directed to ascertain in what way Nature is endeavouring to relieve herself, and no treatment should be adopted which can possibly interfere with this process. Many points of great interest may be remarked in these two cases; for though that of Dr B. terminated fatally, still the post-mortem examination exhibited manifest proofs that tubercle may be removed, or rendered perfectly inert. I look on the destruction of his life by hæmorrhage as an accidental circumstance: the vessel engaged was a large one, and, probably, circumstances might have occurred momentarily to excite the circulation. In his case, ocular proof was had of the means which Nature takes to cure phthisis. In both of these cases, Nature acted, in the one by excreting from the blood a large quantity of fluid, and in the other by the occasional discharge of blood from the immediate neighbourhood of the disease itself, thus relieving the irritation which surrounded the tubercle. I could bring forward many cases of the cure of phthisis, were it not that it would pass the limits which I have allowed myself at the present time; but I may on a future occasion revert to the subject.

Rome, May 29, 1860.

CARCINOMA OF PYLORUS.

By J. HUNTER, Esq., M.R.C.S.E.

The following illustrates very well those cases in which the stomach becomes the seat of carcinoma, and the patient ultimately dies of the disease, without any marked symptoms being manifested during life:—

I was sent for to attend Mrs B——, æt. 61, residing in London, of healthy, robust appearance, excepting a slight sallow tinge of countenance; she has generally enjoyed good health, but has been twice attacked with jaundice. For the past three months her friends have noticed her complexion to become more yellow; she has herself complained occasionally of some little annoyance after meals, which she attributes to indigestion, but never had any vomiting previous to the present attack; appetite usually very good. She now suffers from no particular pain, unless when taking solid food; subsists, now, therefore, entirely on fluids; vomiting and retching constant, bringing sometimes upwards of four pints of clear, limpid, insipid fluid off her stomach at one time: this has been the case, more or less, for three weeks. Alkalines were prescribed, but with no good result. Bismuth and hyoscianus were alike useless. After a consultation with Dr Steggall, calomel was given in grain doses every hour, with opium. This, however, did not effect any abatement of the symptoms, and she gradually sank; the vomit for the twenty-four hours preceding death was of a dark coffee-colour. The friends having kindly permitted a post-mortem examination to be made, the following was the result:—The body was not at all emaciated—rather the reverse, but of a somewhat sallow hue generally. On opening the abdomen, the omentum was found loaded with fat; the stomach enormously distended and firm, with fluid similar to the latest vomited; its coats much congested and attenuated; the structure of the pylorus considerably thickened, and on being cut into, found to be of the consistence of brawn; the orifice and canal leading into the duodendum very much contracted and rigid. The liver and spleen smaller than natural, congested, and breaking down very easily under pressure of the finger: the other organs were healthy.—I cannot ascertain that any relations of the above patient have at any time been affected with cancer; this, coupled with the fact that all the other organs of the body were entirely free from this disease, may give rise to the supposition that it was really a case of simple hypertrophy of the tissue forming and surrounding the pylorus; but from its appearance on section, not showing the parallel white lines so noticeable in the hypertrophical condition of the part, and the peculiar feeling imparted whilst cutting it, I am led to deem it undoubtedly a case of carcinoma. Not being allowed to remove any part, I was unable to avail myself of that most valuable of all tests, the microscope.

Hart street, Bloomsbury square, Sept., 1860.

THE SPIRIT OF THE PERIODICALS.

The present number of the 'Lancet' opens with a report of Mr GRAINGER's Introductory Lecture, which is followed by a continuation of Mr HANCOCK's paper on the *Division of Ciliary Muscle in the Treatment of Glaucoma*. We extract the following portions of the article :—

"Let us, in the next place, examine the results of the operation of iridectomy, according to the published reports of Dr Bader. These operations having been performed at Moorfields, we may confidently assume that they are not obnoxious to Mr Hulke's objection of having been 'practised in cases which were not true instances of this disease' (glaucoma).

"Of 107 cases, 16 are admitted to have been injured by the operation. The eyeball in several cases had to be extirpated after the operation, in consequence of hæmorrhage and the escape of vitreous humour. The suspensory ligament of the lens was ruptured in others, and the vitreous humour escaped ; in one case, from difficulty of seizing the iris, the vitreous humour, with the hyaloid fossa and lens, escaped, followed by half an ounce of blood.

"Of 72 cases, bleeding from the iris into the anterior chamber occurred in twelve, in one case beginning a quarter of an hour, in another a day, after the operation, the latter being followed by suppuration of the globe ; and one case required a counter-puncture, to allow the blood to escape.

"In three cases, hard portions of transparent lens escaped at the time of operation. In another, the lens and capsule, with about one-third of the vitreous humour, escaped through the wound six hours after operation. Some portions of the lens escaped in another case, and some vitreous humour also while removing the remainder of the lens with a scoop ; whilst in seven cases the lens became opaque, without any fragments escaping. The opaque lens, however, was subsequently extracted favourably in several of these cases.

"We are indebted to Dr Bader's candour for these results. We search in vain for any mention of them in Mr Hulke's paper, although it would not be too much to expect that some allusion would be made to them in a paper devoted especially to glaucoma and its surgical treatment.

"Dr Bader's tables include the result of operations upon 84 eyes. Of these—

2 were not so well after operation.
36 were not benefited.

"Of the remaining 46, at the time of operation—

"7 had no perception of light. Of these—
5 recovered perception of light.
2 recovered the power of recognising fingers, one being also able to distinguish distant objects.

"22 had perception of light in degrees varying from faintest, faint, fair, to actual perception. Of these—
3 recovered improved perception of light in portions of the retina only.
5 recovered improved perception of light.
1 recovered the power of recognising objects by a portion of the retina only.
9 recovered the power of recognising objects.
4 recovered the power of reading : 2 small, 2 average type.

"6 had perception of light by portions of the retina only. Of these—
1 was somewhat better.
2 obtained perception of light by whole retina.
2 recognised objects by portions of retina.
1 recovered the power of reading type of average size.

"6 had perception of objects. Of these—
2, who had perception of large objects, were improved.
1, who could see small objects, such as keys, could read average type.
1, who could count fingers, acquired the faculty of reading small type.
2, who had no perception of distant objects, and could only count fingers with difficulty, recognised fingers and distant persons.

"4 could read large type. Of these—
1 was improved.
1, accommodating at from 3 to 10 inches, reads average print.
2 recognise distant objects, and read average type.

"1 patient could see, but not read, large type : reads large letters, and tells the time on a distant clock.

"I have now to offer a few observations upon the results of my operation up to the present time.

"I also propose to add the present condition of several patients upon whom my operation was performed some months since ; and I do this with the greater confidence since Mr Hildige, in commenting upon the operation when first announced, fell into the error of assuming it was mere paracentesis, which, he asserted, produced merely temporary benefit, the symptoms returning in from one to three months ; whilst it has been expected that the Profession would accept and become devotees to the operation of iridectomy from a number of operations, the results of which are calculated at the comparatively short interval of from two to three weeks from the time of operation.

"I have always felt that Mr Hildige's objection possessed great weight, and my attention has consequently been carefully directed to this point, and the result has been to strengthen me very considerably in my original conviction, that my operation did not relieve by evacuating fluid, but by removing constriction. I scarcely know of a single instance in which the patient was benefited immediately, or even shortly after the operation, experiencing the disappointment of a relapse ; whilst, on the contrary, in very many instances, the relief has been so gradual that, for some three or four weeks, it has been scarcely appreciable.

"The class of cases in which improvement is most rapidly manifested, is that of acute and subacute glaucoma, and what has been termed 'evanescent obscurations.' In chronic cases, and those of total blindness, or where a mere perception of light has remained to the patient, the improvement has been of much more tardy manifestation, rarely taking place under a fortnight from the operation, after which it usually increases, and rarely, if ever, recedes.

"The great value of this operation seems to me that, by an almost painless proceeding, however severe the previous suffering has been, the pain is almost invariably removed. Not only is this the case, but, if fairly tried (which I am justified in asserting it has not been by those who appear to be so anxious to disparage it), it will be found that whilst capable of effecting an equal amount of good as 'iridectomy,' it is free from the danger and objections attending this operation. For instance—

"*a.* It is much more easily and rapidly performed, and the incision made into the eyeball is much smaller.

"*b.* The operation is attended with so little pain, that there is no necessity for chloroform ; the sickness and accidents resulting therefrom are consequently avoided.

"*c.* As the eye does not require to be fixed by forceps, the danger of lacerating the 'rotten' conjunctiva, or of rupturing the suspensory ligament of the lens, is likewise avoided.

"*d.* The incision is made at once by a Beer's knife, and does not in any case require to be enlarged by scissors.

"*e.* As the incision commences at the margin of the cornea, and is carried obliquely into the sclerotica away from the cornea (not backwards and inwards towards the axis of the globe, as erroneously stated by Mr Hulke), and as the iris is left intact, and is not to be seized by the forceps nor drawn out by a hook, there is no danger of the lens escaping, being broken up, or so injured as to cause traumatic cataract.

"*f.* The integrity of the iris being preserved, the operation is not necessarily or even beneficially restricted to the upper segment of the cornea, in order to obtain the compensatory support of the upper lid. The patient, moreover, retains the power of adapting his vision to near objects ; and in the majority of cases there is no permanent disfigurement of the eye, or coloboma iridis

"*g.* The iris not being injured, hæmorrhage from its lacerated edges cannot occur ; thus it can neither be necessary to employ a scoop to remove the blood, nor to make a counter-opening to admit of its escape.

"*h.* The incision is so small, that it is impossible for the lens or the vitreous humour in any quantity to escape through it. The necessity of extirpating the eyeball, therefore, from either of these causes, or on account of hæmorrhage, as I have already shown, cannot by any possibility occur.

"*i.* It relieves pain by the removal of the constriction of the eyeball, and the consequent pressure upon the nerves from the undue constriction of the ciliary muscle.

"*j.* By it the impediment to circulation through the bloodvessels is got rid of ; they are placed in a favourable condition to recover their normal state, and the probability of a recurrence of the effusion is greatly diminished.

"*k.* Where it fails, it does so little damage to the eye, that iridectomy may subsequently be performed, if considered beneficial to the patient.

"We have seen that Dr Bader gives the account of 84 eyes operated upon, and the results at the end of from two to three weeks were—

2 not so well as before ;
36 not benefited ;
16 recovered perception of light ;
18 recovered perception of objects ;
12 possessed the power of reading, but of these 5 could read large type before the operation.

"On the other hand, since its introduction in September, 1859, my operation has been performed on 31 patients suffering from glaucoma, and the result of these operations has been that—

10 were not benefited, they remaining in the same condition as before the operation ;
6 recovered perception of light ;
5 recovered the perception of objects, being able to discern keys, pencil-cases, tell the time, &c. ;
10 recovered the power of reading, none of them being able to distinguish a letter, even, at the time of operation.

"I here subjoin an abstract of the last fifteen cases, merely observing that the operations performed for the relief of hydropthalmia, staphyloma, and conical cornea have not been included here, as it is my intention to publish them at some future period.

"*Case* 1. — H. M——, aged forty-four, admitted into the Royal Westminster Ophthalmic Hospital in October, 1859. Of tolerably healthy appearance, but suffered from great nervous depression. The pupils were dilated ; eyeballs hard and large, but free from pain. He was quite unable to go about without assistance, and could not read a letter. The only period at which he could see was early in the morning, just after he awoke from sleep. Upon these occasions objects seemed dim—not single, but doubled, trebled, and quadrupled. His sight was good until four years ago, when it became dim ; two years afterwards he began to see double, at which time he commenced work at a cheesemonger's shop, at gaslight. Impairment of sight increased until two months before admission, when sight became totally absent.

"On October 14th Mr Hancock divided the ciliary muscles of both eyes. His eyeballs became much softer to the touch, and lost the tense feeling which they before possessed.

"He left the hospital on the 1st of November, being very slightly, if at all, improved.

"September 12th, 1860 (eleven months after the operation).—He came to the hospital to-day by himself. The pupils are now of the natural size and shape, and the irides act freely. Has now only single vision. He says that he has several times this summer been into the country by himself ; that last summer he was so blind that he could not go anywhere without being led. Can now read small pica print without the aid of glasses, and tells the time on a watch readily.

"*Case* 2.—S. B——, aged sixty-two, admitted October 3rd, 1859. Acute glaucoma of the left eye. She first experienced pain in the eye seven days previously, and having had to work very hard as a washerwoman, the pain became most violent, preventing her sleeping at night, and extending to the temple and over the brow. The eyeball is very hard, exquisitely tender to the touch, and presents the usual external appearances observed in glaucoma ; the lens is opaque, and of a greenish colour ; the pupils dilated and irregular ; her countenance is very pale, and in-

dicative of great suffering. She can barely distinguish light from darkness.

"October 7th, 1859.—Mr Hancock cut through the ciliary muscle. The pain was entirely relieved by the operation, and did not recur during the fortnight she remained in the hospital.

"Jan. 2nd, 1860.—The patient came to the hospital to-day, and says 'she can now see with the eye as ever, she said,' and is able to follow her employment.

"Sept. 19th (eleven months after the operation).—Her sight still continues good. She says she can read the newspaper without any difficulty.

"*Case* 3.—H. C——, aged fifty, washerwoman, admitted Jan. 11th, 1860. Sub-acute glaucoma. Ten years ago, the right eye became swollen, red, and painful, she having been previously subject to rheumatism. The pain in the course of time ceased, but she never perfectly recovered the sight of the eye. A similar attack, attended with flashes of fire before the eyes, occurred six years ago. As upon the previous occasion, the pain was got rid of; but the sight has ever since been much impaired. The eyeball is pyriform in shape, and the cornea contracted in its diameters and conical. A marked depression or groove runs round the eyeball, corresponding to the ciliary muscle, the eyeball being constricted at this point; the choroid shows darkly through the thinned sclerotic; the lens is opaque, the globe very tense, and an arcus senilis surrounds the cornea.

"Jan. 13th.—Mr Hancock divided the ciliary muscle.

"Feb. 14th (one month after the operation).—The eye has now the appearance of the sound eye; the sight is excellent, and she has the power of adapting the eye as easily to near as to more distant objects.

"Sept. 18th (eight months after the operation).—The sight of the eye is equally good as at last report. She says she has now her usual sight, and can read the newspapers.

"*Case* 4.—C. B——, aged fifty, admitted on the 25th of January. Cataract and glaucoma. Nine years ago, she had an attack of inflammation in the right eye; after which the sight of the eye gradually failed, until, in a few months, it entirely left her. Four years ago, her left eye became gradually dim and misty, and she saw coloured rings surrounding the candle. She never had any pain in the eye. She is now quite blind with her right eye, unable to distinguish light from darkness. The lens is completely opaque, of a deep yellowish colour, and dislocated, its upper margin being directed backwards, whilst its lower rests against the iris, which is immovable. The left eye is glaucomatous; the globe is hard, and the lens of a greenish colour; the iris bulging forward, insensible to light, and the pupil dilated and irregular. She is unable to distinguish the largest print, but she can see faces indistinctly, and if the hand be held up before her eye she can with difficulty count the fingers.

"March 2nd.—Mr Hancock divided the ciliary muscle in the left eye.

"23rd.—Can discern faces and objects held before the eyes better.

"*Case* 5.—J. C——, aged fifty-seven, admitted on the 15th of February, 1860. Glaucoma (chronic). Has almost completely lost the sight of the left eye, being just able to perceive light; has occasional pain and flashes of light in the eye; the eyeball is hard; the pupil insensible to light; humours turbid, with some opacity of the lens, so that the retina and choroid cannot be seen; there is a distinct greenish reflection from the pupil; the cornea is not prominent, but is rough on its surface, though transparent; if placed opposite the light, he can tell if a dark body be moved before his eyes, but cannot distinguish its form.

"Feb. 17th.—Mr Hancock divided the ciliary muscle in the left eye.

"March 1st.—To attend as an out-patient. There is no apparent improvement.

"Sept. 14th (seven months after the operation).—Can discern a pencil-case and watch when held before him; can also discern people and the colour of their clothes."

Mr BROKE GALLWEY relates in the same journal the following case of *Sanguincous Meningeal Effusion*:

"Under the above heading, Dr Wilks has lately produced, in the 'Guy's Hospital Reports,' an able and practical paper, that has an intimate relation to much that we meet with in the domain of cerebral pathology. I avail myself of his introduction of this subject to the Profession to bring the following case under the notice of your readers:

"Gunner J. M——, Royal Artillery, aged twenty-six, was brought into the hospital here at nine a.m. on the morning of the 18th of May, in a state of partial insensibility, having been picked up the preceding night by the picket in a public-house, on the ground-floor of which he was reported by the landlord of the same to have been lying insensible from four p.m. of that day. Very naturally considered by the sergeant of the guard, into whose hands he was consigned by the picket, to be only "dead drunk," he was deposited on the floor of the lock-up room until the morning after, together with the other worthies consigned to his care, in the different stages of oblivion to which the weakness of their heads or strength of their finances had brought them. I must plead guilty to having at once endorsed this view of the man's complaint, especially as he exhaled a strong effluvium of rum, and discharged a quantity of this fluid from his stomach immediately after admission into the hospital. He was capable of being roused, and even of responding to questions when loudly proposed to him, but immediately after would relapse into unconsciousness. His pupils at this time were of natural size, though sluggish; pulse oppressed, and somewhat slow; skin nowise remarkable. Having due regard to his immediate antecedents, the patient was put to bed, and merely ordered to be watched. Nothing remarkable transpired during the first twenty-four hours after admission; but at the visiting hour of the day after, some ptosis of the right upper eyelid attracted attention, with eversion of the corresponding eyeball; and now also the grasp of the right hand was found to be materially weakened, together with the patient's control over this entire limb. The leg of the same side was unaffected; the facial muscles were not implicated; and his speech, which had now returned with returning consciousness, was distinct and uninvolved. He was now able to recollect and relate the occurrences antecedent to his attack. He remembered to have been drinking in the public-house, but at that point his memory deserted him. He admitted that his habits had been intemperate; and I ascertained a little later, from one of his comrades who had known him well and for a long time, that he was inveterately addicted to the bottle. I ought to have stated that the patient's head was carefully examined for external evidence of injury, but without leading to any results in this direction; while, throughout his illness, he made no complaint of pain in any part of the same.

"By the third day, the paralytic phenomena had increased slightly, but there was no corresponding implication of the intellectual faculties, nor was there any irritative development in the muscles of the affected arm. The urine was examined for albumen, and traces of that substance were found, yet insignificant in amount. The pupil of the right eye had now become much dilated, and was insensible to light; the ptosis and eversion continued. Opposite pupil lively, and of natural size.

"This patient died on the sixth day after admission, his case having undergone very little alteration from the state of things recorded in the foregoing details. To the last he continued free from coma, screamed out at times towards the close of the scene, and died at length exhausted.

"The autopsy of Dr Wilks' *fifth* case recounts almost so exactly what disclosed itself in that of J. M——, that this physician's description will fit in here almost without the transposition of a sentence, or the alteration indeed of a line:—

"'The head presented no external signs of injury, and the bones were not fractured. On removing the calvaria, the dura mater was of a dark colour on the *right* side, and was flaccid. On lifting this up, its inner surface, as well as that of brain, was seen covered with blood, being contained, in fact, in the cavity of the arachnoid. The blood was fluid, or in form of loose coagulum. The whole of the right half of the brain was surrounded by the effused blood, and which had evidently compressed it; this was seen by the septum of the ventricles being pushed over to the left side. The blood had passed down to the base,' and was found also in some quantity there. 'The left hemisphere was unaffected; there were no inflammatory products to be seen by the naked eye. The brain itself was carefully examined, in order to discover any breach of surface as a source of the hæmorrhage, but *none* could be found. No laceration could be found in the sinuses or meningeal vessels, from which the blood could have flowed.'"

"I may add that the brain did not disclose any, the least, appearance of bruising.

"The effused blood bore the appearance of being quite recent, having undergone no change of colour or chemical alteration indicative of having been long separated from its natural channels. The left ventricle was the seat of a vast effusion of limpid serum, into which no blood had found access. A much smaller quantity occupied the right; and the third and fourth ventricles also were distended with the same. The substance of the brain was healthy throughout, the left corpus striatum and optic thalamus being no exception to this condition. The vessels of the brain were sound, and, judged by the naked eye, free from any degenerative tendency. There was nothing about the origin or course of the third nerve to explain the ptosis of the right upper lid; nor was there any sufficient cause apparent for the paralysis of the right iris more than of the left, which latter had been lively throughout under its natural stimulus. The walls of the heart were preternaturally thin; valves all healthy. External capsule of liver extensively figured with deposits of fibroid degeneration, laid down, I may almost say, in sheets—that peculiar appearance so often met with, and so generally laid at the door of chronic inflammation, and which Dr Wilks himself, I believe, conceives to have its origin in a change *sui generis*, probably the offspring of syphilis, or of alcohol, or of both. Tissue of kidneys healthy, but the secreting structure of both, more particularly of the right, in a state of intense and universal venous congestion, to which the term of venous apoplexy might not be very inapplicable. Both renal veins much dilated.

"*Remarks.*—The leading points of interest about the foregoing case I take to be the following:—

"1. That a man is not always to be taken for dead drunk, even though picked up insensible on the floor of a public-house, with the odour of spirit about him at the time.

"2. That a large effusion of blood may be discovered on the surface of the brain, and yet elude our closest inquiries into its source.

"3. That such large effusion of blood is not necessarily productive of coma, this symptom, from first to last, having been absent in the present case.

"Further, it is observable, that although the effusion of blood was upon the right hemisphere, the paralytic phenomena were *not upon the left*. I take this to point to the *recent* origin of the effusion; for, although not existing in connection with the centres of motion, its amount was so great as to have produced a considerable indentation of the hemisphere towards the ventricle, the long persistence of which, had such been the case, I doubt not, would have influenced the functions of the corpus striatum and optic thalamus. The excessive effusion into the left ventricle, I take to have been the cause of the paralytic phenomena. Blood-poisoning from renal causes, plainly, will not explain the *ortgo mali*, or the symptoms during life, neither convulsions nor coma having been present; nor will degenerated cerebral vessels.

"On these several accounts, I think the present case affords a striking illustration of the opening remarks in Dr Wilks' paper, already quoted:—'Of all the difficult cases admitted into hospitals, those are the most perplexing where the patients are brought in in an insensible condition, and unable to give any account of themselves. A man, for example, may be picked up in the street, or carried from a neighbouring public-house, or place of low resort, and the surgeon has to choose between injury, poison, or disease as a cause of his insensibility; and then, again, to elect between the probable forms of these. In such cases, the post-mortem examination will generally enable us to determine the nature of the case for the purposes of justice. Occasionally, however, even this is difficult or impossible, and the inspection after death will throw only a partial light upon it.'"

The 'Medical Times and Gazette' contains a continuation of M. CLAUDE BERNARD'S Lectures on *Experimental Pathology*. The subject of the pancreatic secretion is resumed. We extract it:

"We showed you, at our last meeting, the manner of obtaining the pancreatic juice, and the operative proceeding with a view to this end. The dog on which the experiment was performed on Friday last is still alive, and the wound inflicted on the abdomen is, as you observe, almost completely cicatrised. The pancreatic duct, however, having unfortunately been cut by the ligature used to secure the india-rubber recipient attached to the tube, we have not been able to collect so much of the fluid as we desired, in consequence of this accident; but we have secured a sufficient quantity for all practical purposes. We might repeat the operation several times in succession on the same dog without any serious inconvenience, as the animal (when properly selected) seldom suffers much, notwithstanding the delicate nature of the organs wounded. The peritoneum of the dog is not nearly so sensible as that of man, or even of the horse; and hence, in the latter, it is almost impossible, without incurring great danger, to establish a pancreatic fistula. Permanent apertures of this kind cannot be kept up for any great length of time even in dogs, on account of the rapidity of the healing process in the animals on which they are practised; and hence the operation must either be repeated several times on the same animal, or several animals must be employed at the same time, if a large quantity of the fluid is desired. Spontaneous fistulæ of the pancreatic duct are occasionally to be met with in the human subject; but those of a genuine kind are rare. I have, however, myself observed two cases in which this lesion was supposed to have taken place. In one of these individuals it was remarked that, when the digestive organs were in a quiescent state, no fluid appeared to flow from the fistulous opening; but when the stomach was in a state of activity after the ingestion of food, a profuse secretion flowed forth from the aperture; and such was its abundance, that the patient was under the necessity of keeping a towel constantly over the opening. On examining this fluid, I found it decidedly alkaline; but, apart from this property, it neither resembled the pancreatic juice, nor any other normal secretion of the economy.

"Is the pancreatic juice found in man and obtained from the lower animals identical? To this I am prepared to answer in the affirmative; and if differences have been observed, I strongly suspect that, as in the preceding case, they are to be attributed to the unhealthy condition of the gland in the human subject in whom the fistulous opening existed; for, on making infusions with the pancreas obtained from condemned criminals, by allowing it to macerate in tepid water, a liquid entirely similar to the pancreatic juice in the canine species was obtained. In the normal state, therefore, the secretion in man and in the dog is in all respects the same; and this is not strange, seeing that the gastric juice in both is identical.

"We here exhibit a considerable quantity of pancreatic juice obtained from the dog operated upon a few days ago. You observe it gives a distinct alkaline reaction—a property constantly found in this liquid in the healthy state. Another of its peculiarities is, that it speedily undergoes chemical alterations, and that, perhaps, more rapidly than any other of the secretions of the economy; and in the changes which it undergoes, there are circumstances which merit our attention. As it cools, a precipitate is soon observed to take place: the chemical composition of this precipitate is not perfectly known; according to M. Robin, it is formed of lactate of lime. It consists in minute prismatic crystals. In the tube which I hold at this moment they are perfectly visible to the naked eye, under the appearance of small whitish granulations. Another important modification which the pancreatic secretion undergoes shortly after being drawn from the duct, is the diminution of its coagulability under the influence of heat; when recently taken from the fistula, it coalesces into a solid mass when placed for a few instants over the flame of a spirit lamp; but when it has remained for some time outside the economy, this property quickly diminishes.

"(The comparative experiment is here performed before the class with full success.)

"But the fundamental and characteristic property of the pancreatic juice—that which distinguishes it from all other secretions—is that it enjoys the peculiar power of forming an emulsion with fatty substances and with oils. By adding some of this latter fluid to the pancreatic juice contained in this tube, you observe that a white emulsion is immediately produced; and it persists during a considerable space of time. This singular emulsifying property is peculiar to the pancreatic juice, and is not remarked in connection with saliva, the gastric juice, or the bile; it is true, however, that alkaline secretions (saliva and bile, for example) produce analogous effects, by partially saponifying the greasy bodies with which they come in contact; but in the pancreatic fluid, this property exists, independently of its alkaline reaction, and the emulsion produced is of a different nature, not being the mere result of a chemical combination. This fact enables us to understand the main uses of the pancreas in the economy; it is principally subservient to the digestion of fat, which, unless in a state of emulsion, could not pass into the absorbent vessels. After tying the pancreatic ducts in a dog, and feeding it with fat, this substance is found undigested in the animal's excrements; and clinical observations fully confirm the results of experimental investigation in this case, for in patients affected with cancerated pancreas an oily matter has frequently been discovered in the patient's stools; probably the residue of fatty substances which he had not been able to assimilate.

"We are now fully acquainted with the principal properties which are enjoyed by the pancreatic secretion; it only remains for us to examine its relations with the nervous system. In this respect it completely differs from the other secretions which we have hitherto studied. The remarkable effects of innervation upon the production of saliva and gastric juice have been fully explained to you; but the influence of the nervous system upon the pancreatic apparatus appears to be of an entirely different order. When the nerves of this organ are acted upon—whether excited by the galvanic stimulus, or paralysed by a transversal section—the result is identically the same: the secretion grows abundant and uninterrupted, while a profuse diarrhœa is constantly established; the extirpation of the semilunar ganglia produces similar effects, and under these peculiar conditions the pancreas pours forth a peculiar fluid, which no longer exhibits the physiological properties of the secretion. A fundamental difference here exists between the salivary glands and the pancreas; in both these organs the section of the sympathetic nerve accelerates the circulation, but in the salivary apparatus the normal secretion is far from being thus modified.

"When the pancreas, the functions of which are intermittent in the healthy state, is thus compelled to furnish a continuous secretion, the produce which it pours forth is no longer a normal fluid; it is a watery production which possesses none of the characteristic properties of pancreatic juice. In this experimental fact, we meet with the confirmation of the general views we have elsewhere expressed on the mechanism of secretions. We admit that in all secreting organs a special and characteristic substance is produced, and that an intermittent flux carries it away; it is therefore absolutely necessary that the gland should enjoy certain intervals of rest, during which this peculiar compound is formed; and when the moment of excretion has arrived, an abundant flow of blood to the part takes place, and carries off the special produce of the gland by means of a profuse exudation. But when secretion is all at once rendered continuous, the characteristic substance is no longer produced within the gland, and the watery vehicle alone escapes from the secreting apparatus.

"You perceive, gentlemen, that the great object of all the operations which we have performed before you has been the examination outside the economy of the various secretions which concur in the digestive process. To Réaumur and Spallanzani belongs the honour of this new method of investigation: by them it was originally inaugurated; and at the present moment we have operative proceedings by which almost all the secretions concerned in digestion can be produced. We can thus not only carefully examine and accurately ascertain the properties of each and all of them; but we can also imitate them, and artificially prepare the digestive juices. To a certain extent these secretions can be obtained without the operative measures we have described and practised before you, by simply macerating in water the organs whence they come; but neither in such quantities nor in such a state of purity as when the usual method has been employed. It now remains for us to describe the application of this method to the biliary secretion; and this subject will occupy the last lecture of the present Course."

Dr GOODFELLOW continues in the same journal his Lectures on those diseases of the kidney generally known as *Bright's Disease*. He observes:

"It seems to me desirable for clinical purposes, more, I confess, than for any other practical object, that I should arrange the several agents reputed to be instrumental in the causation of these diseases under three categories.

"1. Those whose action is upon the blood primarily, and upon the nervous system, and the tissues of the organ secondarily.

"2. Those which affect the nervous system primarily, and the blood and tissues secondarily.

"3. Those which, either by direct or reflex action, affect the tissues of the organ primarily, and its own nerves secondarily.

"Now, although there are probably some advantages in this arrangement, yet I do not overlook the objections to which it is open.

"For example, where ought we to place alcohol and other allied finids? I shall place it under our first class. You will see, however, by-and-by, that there are strong grounds for including it under the second. So also with scarlatina; but I have had less difficulty as to where this ought to go. I have placed it under the first category, believing as I do that it is essentially a blood disease, and that its action upon the nervous system is altogether secondary. Yet some writers upon this disease think that its primary influence is altogether upon the nervous system.

"The most comprehensive and, at the same time, the most practical way of including all the possible causes of these diseases, would be this:—Any substance, state, or condition, which is calculated to impair the nutrition and secretion of the organ, retard the circulation of the blood in its vessels, or irritate, directly or by reflex action, its nerves and tissues, may be regarded as exciting or engendering causes; and any condition of the body, natural or acquired, which renders it more than usually impressible to the influence of certain morbific agencies, will, of necessity, predispose to the disease, and make those substances, states, or conditions, efficient causes.

"*Under the First Division* I put scarlatina erysipelas, measles, variola, cholera, struma, syphilis, phthisis, gout, rheumatism, &c.; alcohol (and in this I include all fermented alcoholic fluids), turpentine, ether, naphtha, chloroform, &c. You will see that I have placed alcohol and other hydro-carbons last; and I have done so, because I have some doubts whether they ought not to be placed under the second division.

"*Under the Second Division* I put cold, cold and wet, and more especially sudden and great transitions of temperature, injuries, or diseases of the brain and spinal cord, or sympathetic system, whether from centric or eccentric causes, anxiety of mind, mental shocks, &c.

"*Under the Third Division* I am disposed to include all injuries and mechanical causes of irritation: as blows, the presence of calculi (microscopic or larger), cantharides, and other irritant poisons, Onanism (Rayer), excessive venery (Rayer), amenorrhœa, and other uterine affections; and, lastly, diseases in other parts of the urinary apparatus which are calculated to produce reflex irritation in the kidneys.

"The first on our list is *scarlatina*. There is no doubt that scarlet fever is one of the most frequent causes of kidney disease, attended with albuminous urine. What is its mode of action? To answer this question satisfactorily, it will be necessary to consider what takes place in the system generally, as well as in the kidneys, in this disease. It will assist us in understanding the *modus operandi* of this and the other assigned

causes, especially cold and wet, and alcoholic and allied fluids, if I make a few remarks upon the physiology of the urinary secretion.

"In scarlet fever what is the condition of the body generally? That the skin, and some few of the mucous membranes, are not the only parts which suffer, I shall endeavour to make evident to you. The capilliary bloodvessels of the skin are not the only ones that are congested by the retarding, stagnating influence of the 'poison.' The vessels of every structure and organ of the body suffer, if not to an equal, yet to a very great extent. It is true we cannot see the precise condition of the vessels in the internal organs as we can in the skin, and in the mucous membranes of the eyes, nose, mouth, and fauces; but we have equally certain evidence in the symptoms.

"The *circulation in the brain and nervous system* is also effected. We have evidence of this in the disordered function of these important organs.

"The *muscular system* is also effected. This is evident from the pain felt, in many cases, from motion and pressure, much resembling rheumatism. In fact, there are strong grounds for believing that the scarlatinal poison acts much in the same way as the true rheumatic poison, and that there is a close and intimate resemblance, in many respects, between them.

"That the *serous and synovial membranes* suffer, we have evidence in the frequency of effusions in both, and in the pain and stiffness in the joints.

"That the scarlatinal poison *irritates the glands*, the constant pain, swelling, and frequent suppurations in or around them attest. There is also a remarkable tendency to exudations in scarlet fever, and an exudation of a very low character—not of fibrinous matters readily organisable, but of a low form of albumino-fibrinous matter, which has a great tendency rapidly to be converted into a sort of albumino-purulent state, or even into true pus. The great tendency to the formation of pus is shown by the frequent abscesses in the areolar tissue beneath the skin and some mucous membranes, and in the neighbourhood of the glands, and in the purulent infiltrations between the muscles. There is also very often an exudate of a low form of albumino-fibrinous matter on the *free surface* of the mucous membrane of the fauces, and of a dirty-looking puriform serosity in the areolar tissue, beneath the mucous surface of the pharynx and larynx. There is in most cases of scarlet fever a deficiency of true fibrine,—hypinosis, as it is termed.

"In the mild forms there may be an increased transudation of the *liquor sanguinis*. The tumefaction that is so often observed, and the sensation felt by the patient, as if he were generally swollen, may in part be due to this transudation, as partly it is undoubtedly due to the state of congestion of the vessels generally.

"With reference to this congestion, it seems to me that writers upon the exanthemata have too much relied upon simple congestion as the cause of the eruption, and have overlooked the direct influence of the "poison" upon the red blood-corpuscles. We know that several substances, some of them poisonous, give a scarlet hue or vermilion tint to the red blood-corpuscles,—urea and several other animal products; arsenious acid; the nitrate, phosphate, proto-carbonate, and sulphate of soda, and the sulphate of magnesia: but all the sulphur and hydro-carbon compounds darken them. This is certainly an interesting subject for further investigation, which might lead to more certain information as to the real nature of the scarlatinal poison. There is very strong evidence that it is volatile, and that it is a product of the animal body, and therefore an alteration probably of some normal animal principle. It may be closely allied to some of the odorous excreta of the body, for no one who has had under his charge several patients in one ward labouring under these exanthemata can have failed to detect a peculiar odour belonging to them. I am quite sure that I know the scarlet odour and the small-pox odour."

The Author, in continuation of his remarks on the characteristics of scarlet fever, applies the argument to the state of the kidneys, and goes on to say:

"We are now in a position to account for what we observe in the urine during life, and the kidney itself after death.

"Those who have taken the pains carefully to examine the urine day by day, have found albumen even at an early stage, but certainly almost always from the commencement of the desquamation. In severe forms the urine has not infrequently been found to be bloody,—that is, to contain red blood-corpuscles, in addition to the serum. Is it surprising that we discover albumino-fibrinous casts, epithelial casts, blood casts, and red corpuscles; and if we have these in the urine, after having traversed the tubules, is it not possible that the tissues of the kidney are infiltrated with sanguineous effusion, and also with this low form of albumino-fibrinous material?

"This morbid process going on, in what way is the function of the organ likely to be affected, and what means are there for the removal of these exuded matters? There are three:—the tubules, venous absorption, and lymphathic absorption. Let us inquire how far these means are in a state to perform this office. The tubules are more or less obstructed with solid matters, which in some parts may impede, in others prevent any escape in this direction. The circulation in the venous radicles is nearly arrested, and but little absorption can take place in this way. The lymphatics are pressed upon by the exuded matters themselves and by the distended blood-vessels, while the whole is closely invested by a capsule composed of an inelastic and, to a certain extent, a tissue not readily extensible. These agents of absorption are not in a condition very favourable for the adequate discharge of their office. These three agencies failing, there is no way of escape for the exuded matters, that at this time probably have become mixed with a large proportion of the constituents of the urine. If any absorption by the lymphatics take place, only the more fluid portion can be taken up, and probably this is more or less mixed with the urinary constituents. The secretion also is all but arrested, and the whole mass of blood is deteriorated by the presence of the urinary excrements: ill prepared as it was before for this additional cause of vitiation, its own previous diseased condition is now reacting upon itself. It has probably not recovered its normal condition before it is exposed to another and even more serious cause of deterioration; and this fluid, upon the purity and soundness of which depend the well-being of the whole organism, the nutrition of the tissues, the due performance of the functions of organs the most vital, is circulating through vessels and tissues that either are, or but lately were, weakened and disabled by the primary disease. You cannot, therefore, be surprised that anasarca occurs in this complaint even from a condition that would not produce it if the general tissues had been healthy and had possessed more tone.

"Now, suppose a person dies from the disease on the fifth, sixth, or any later day about this period, and supposing that the morbid process in the kidney is such as I have described, what morbid appearances would you be prepared to find? The vessels are greatly distended; there has been more or less blood stasis in some parts, principally in the veins and in the Malpighian tufts; the kidney then will be in a state of great sanguineous congestion or engorgement—there will be observed numerous red dots and streaks, and the general tissues being infiltrated with a kind of sanguineous transudation, will either present a diffused redness, or this redness will be more or less intermixed with whitish or yellowish white lines. The whitish parts will be due to exudative matter. On the surface there will be also a diffused redness; or here also there may be a mottled appearance, the darker parts being due to the arborization of the minute veins. The tubules will be more or less distended with blood-casts, exudative matters, and cast-off epithelium. Now, with all this the capsule has not yielded much to the internal pressure, and the kidney, although larger than normal, is not so large as at a later period after anasarca. This state of engorgement, exudation, and desquamation will of course vary in proportion to the severity and duration of the disease; but, subject to this, it will be more or less as I have described it. You will see, then, that this state very closely resembles, is indeed identical with, the first form of Rayer, as figured in his Atlas, pl. vi. fig. 1, and pl. x. fig. 3, large diagrams of which you see before you. It is the same as the congestive stage of the large white kidney of Bright and Wilks, and an early stage o the first two of Rokitansky.

"Gentlemen, I do not wish you to go away with the notion that this state, as I have described it, occurs in every case of scarlatina; but yet it is, I believe, an accurate description, modified according to the severity of the disease, and the period at which death has occurred. If the fatal event has taken place very early, there will be nothing more seen than intense congestion, with probably some extravasation; and the longer time that elapses between the commencement of the attack and the fatal issue, the greater will be the change in the structure of the kidney. If the attack of scarlatina be mild, although death does not occur and we have no opportunity of seeing the kidney, yet we may easily imagine that the congestion will be much less considerable throughout.

"There is a very general impression that dropsy is more frequent after mild attacks than after severe ones, or at least as frequent. If, therefore, the kidney undergoes such extensive changes in the severer cases, the reverse of this ought to be the case. I am, however, not quite sure that there is a greater liability to dropsy after mild attacks, nor do I think it would be nearly so frequent after the mild attacks of the disease, if the same care and precaution were observed in what may be called the 'after-treatment' of the disease. In severe cases the patients remain under strict medical treatment so long as the slightest signs of the disease or of its effects are observed. In mild cases, on the contrary, I believe that patients are very often supposed to be cured before the poison is really out of the system, and any exposure to cold, or to cold and wet which is sufficient to produce a chill, or any debauch or imprudence in drink or diet, will soon lead to all those states of the kidney, and of the organs and tissues of the body generally, which I have described.

"I think it necessary here to warn you against the notion that there is less danger of a relapse or of dropsy after a severe attack than after a mild one. After any attack of scarlatina, however mild it may be, you may rely upon it that great damage has been sustained by the blood and tissues of the body, and your patients ought to be emphatically recommended to exercise great care and caution if they wish to avoid the risk of an attack of dropsy, or some other sequela of scarlatina. After a severe attack, however, a considerable portion of time elapses before the blood and tissues have entirely recovered their normal state. During the ten years that I was at the London Fever Hospital, it was my lot to witness several relapses into the disease, in which there was a return of the eruption, of the sore-throat, and of the general inflammatory condition. I have, on several occasions, seen three relapses in the same individual, even when the first attack was one of a very severe character; and if you will carefully watch the cases in the wards, you will find that few persons labouring under severe forms of scarlet fever escape a partial return of the feverish symptoms, and also of the eruption.

"But, to consider the subject with more especial reference to the kidney, suppose that the patient does not die at the period that I have mentioned, and that he is attacked with dropsy. If he is carried off at this time by convulsions, or any other immediate cause of death, the kidney will be in much the same state as I have already described, except that its tissues and its tubes may be infiltrated by a greater quantity of fluid, it may itself have become dropsical. If, however, he has lingered on for some months, the anasarca, although at times checked for a little, yet in the end has increased, and he then dies from coma, or convulsions, or from effusion in one or more of the great serous cavities, or from inflammation in some parenchymatous organ, or he is suffocated by the œdematous condition of the lungs,—in what state should we expect now to find the kidneys according to our view of the morbid process? In this case the hæmatin will have disappeared; some of the corpuscles, and the blood and other casts with which the tubules were clogged, will have been discharged, or the tissues will be infiltrated with serosity, and the albuminous croupy exudates may in part have escaped by those few other tubules, which have become pervious, and in part have remained in tubules and Malpighian capsules, together with the altered blood, and the desquamated and degene-

rated epithelium by which they have become infarcted, impervious for the passage of the urine. The same inflammatory exudates still remain in the tissues, or they may have undergone a sort of gelatinous metamorphosis more or less abounding in fatty matter, and the tubes themselves in many parts may be wasted and obliterated from the pressure. The smaller arteries being in like manner pressed upon, any further supply of blood is cut off, and there is, consequently, an anæmic appearance of the tissues generally, with, here and there, a few congested venous radicles. All this, for the most part, has taken place in the external, secreting, or cortical portion of the organ, which has consequently increased in thickness at the expense of the internal or medullary or excreting portion, and the fibrous investment, having been exposed for weeks or months to constant pressure from within, has now yielded considerably, so that the size of the kidney may be even three or four times greater than in the normal state.

"Here, then, we have a kidney closely resembling the second and third forms of Rayer, as figured in his 6th plate, fig. 4—a large diagram of which is also on the wall, the large white kidney of Bright and Wilks; and the third and fourth forms of Rokitansky.

"That this is no imaginary description, many of you have seen in the dead-house, and many may still see; and such are the processes, as I think, by which these morbid states are produced.

"But there still remains some little difficulty with regard to this part of our subject. It is perfectly legitimate to inquire how, if the kidneys are so much congested, albumen is not more frequently—indeed, almost always—found in the urine? I am, however, not quite sure that if it were carefully looked for in a sample of urine, taken from the whole quantity passed daily, some traces might not be found. But even if some be transuded, as some may be, even in health, there are three ways at least by which it may be removed from the true urinary constituents before their exit from the convoluted tubules. It may be absorbed by the tubules themselves; it may also be removed by the lymphatics and the veins. The lymphatics alone, with their wonderful power of absorption, and, by means of their strong muscular walls, of circulation, also will remove large quantities of albuminous fluid in a short space of time, if these vessels be not pressed upon and disabled by more solid exudates, and by the general turgescence of the vessels. The solid matters must undergo a process of liquefaction before they can be taken up, and I have no doubt but that this often takes place without our knowing the curative process that has been going on beyond our sight. Our patients may often have been near a fatal condition of things without our being aware of it, and from which they have only escaped by the *vis medicatrix*, acting through the lymphatics."

Mr Symonds contributes to the same journal some observations on the *General Treatment of Patients before and after Surgical Operations*, especially with reference to the possible internal lesions, the air of the hospital, and food of the patient. Mr J. S. Walker, of Hanley, reports the following *Case of Successful Operation for the Radical Cure of Hernia*:

"William G., aged 30, married nine months, boiler-maker, a pale thin man, of good constitution, never had a day's illness before eighteen months ago, when, lifting a large piece of iron, he felt a tumour come in his groin; since that time has not been able to follow his occupation with any comfort, on account of the rupture giving him pain.

"June 16.—Applied to me, complaining of the tumour. Upon examination, found a large inguinal hernia on the right side; the patient had repeatedly tried to wear a truss, but could not, because the gut slipped from under it and bulged at the side: he expressed, at the same time, a desire, if possible, to have an operation performed upon him to make a perfect cure. Ordered an aperient pill, with a senna draught in the morning. Waited until June 21, as he was so excited when told he could be cured by an operation that I did not consider him in a state to bear so severe a shock.

"21st.—The patient having been placed, under the influence of chloroform, upon his back, with the knees drawn up, I proceeded to perform Mr. Wood's operation: first, making an incision of an inch in length over the tumour, detaching the scrotal fascia from the skin, then invaginating the fascia into the canal with the little finger; second, in passing a strong, well-curved needle, armed with a hemp ligature thread doubled, guided by the finger through three points in the canal,—the conjoined tendon and the triangular fascia forming the posterior wall,—then withdrawing the needle, holding an end of the ligature in right hand, then passing it again through the external pillar of the ring close to Poupart's ligament forming the anterior wall—the needle now only carrying one thread; then, placing a round boxwood plug over the canal, tightening the first ligature, with the little finger in the canal pressing up the gut; finding it compressed the canal completely, tied it very tight over the plug; then replacing the integument, put a stitch into the skin to close the external wound, leaving one loose end of thread hanging out, which was tied over the plug lengthways, forming + over the plug with the other ligatures. He was then placed in bed, being very sick from the effects of the chloroform. Tr. opii 40 ℥ statim sumend., with soda-water at intervals.

"22nd.—Felt comfortable; progressing favourably, with the exception of a feeling of tightness at the seat of the operation.

"23rd.—Great pain over the lower part of abdomen, increased on pressure; tongue furred; pulse 160. ℞ Pulv. opii gr. j., sumat. omni 2nd. horis.

"24th.—Easy; had taken four pills; the pain being relieved, left them off; tongue cleaner; bowels relieved; pulse 86.

"25th.—Had a severe cough, which caused great pain in abdomen, which is very tender on pressure; tongue furred; examined chest; both sides equally resonant on percussion. Auscultation; ronchus and sibilus all over right side, both behind and in front; left lung natural; pulse 96. Ordered spt. terebinth. rect. applicand. thoraci. To take the following:—℞ Tr. hyoscyami, ℥vj.; pulv. rad. ipecac. gr. iij.; mist. acaciæ, ℥j.; aqua addc. fiat, ℥v. M. ft. mist. capiat ℥j. om. tertia horis.

"26th.—Much improved; tongue clean; bowels relieved; cough better.

"28th.—Removed plug; wound nearly healed.

"From this date he recovered without a single bad symptom.

"July 12.—Applied a piece of soap-plaster over the cicatrix, then the truss. Allowed him to get up; but the patient, thinking he was quite cured, left the house after my visit, and walked two miles to see his mother-in-law; has never felt the slighest inconvenience from the rupture or operation.

"Your readers will see that I have slightly modified Mr Wood's operation; but at the same time the result will show the good effects of the operation, besides drawing their attention to it, which is quite a recent discovery, showing the great advantage of this mode of procedure, which ought to be considered one of the great discoveries of this age."

Mr Figg continues the subject of *Turning in all Cases of Labour*.

Certificates of Death in Scotland.—Last week, a deputation of the Glasgow Faculty of Medicine, composed of Dr Scanlan, Dr W. E. C. Clark, Dr Donaldson, Dr M'Carron, and Mr Walker, met Lord Brougham by appointment at Glasgow, and brought under his Lordship's notice the objections entertained by them to the system practised in Scotland to procure certificates of the causes of death from medical practitioners; and Mr Walker offered a few remarks on a plan which, if substituted for the present defective system, would be considered by the Faculty as satisfactory. After some conversation, his Lordship said that the better course would be for him to have a conference with the Chancellor of the Exchequer on the subject. Mr Gladstone had engaged to visit him at Brougham at the end of October, when the matter would be gone into, after which he would advise the Faculty how to proceed.

OUR NOTE BOOK.

TRACHEOTOMY IN CROUP.

Before the Boston Society for Medical Improvement, as reported for the 'Boston Medical and Surgical Journal' for June 14th, Dr Bigelow expresses his opinion upon the above subject. He says that "in very young children it rarely avails, while in older ones it may be of considerable value; that after the age of three years the chance of life is, perhaps, increased by it; that after that period the ratio of recovery with operation probably increases with the increase of age; but that in *very young* children recovery after operation is rare, probably not greater than without it."—'American Medical Monthly.'

QUININE AND ABORTION.

Edward Warren, M.D., Editor of 'The Medical Journal of North Carolina,' in the May issue of that journal, commenting upon an article from our *Summary*, says, "We have found nothing more likely to produce abortion in pregnancy than the administration of large doses of quinine."—'American Medical Monthly.'

TANNIN AS AN ANTIDOTE TO STRYCHNIA.

As the results of many experiments performed on rabbits and dogs, Dr Kurzak comes to the conclusion that tannin promptly administered is the best antidote in poisoning by strychnia. From twenty to twenty-five times the quantity of tannin is necessary; but even a larger amount should be administered, as the contents of the stomach, and especially gelatine, may absorb a portion. Tannin is the more eligible a remedy, inasmuch as it is easily procurable in the shape of gall-nuts. A portion may be rapidly reduced to powder and administered in water, while an infusion or decoction is prepared. For every grain of strychnia at least two and a half drachms of the gall-apples should be given. It will, indeed, be most prudent to administer a still larger quantity, especially when vomiting occurs. The experiments made by the Author with green tea show that this also possesses a certain amount of efficacy; but, as it requires to be administered in such large doses, it becomes itself almost a poison. It can, therefore, only be of use when a very small quantity of strychnia has been taken, or as a mere adjuvatory. Coffee exerts still less effect. Oak-bark, containing 8·5 per cent. of tannic acid, may be advantageously used when the oak-apples are not accessible; and various other substances containing tannin, as acorns, horse-chesnut bark, green walnut-shell, &c. Vegetable acids must be avoided during the treatment of strychnia poisoning by tannin, as they favour the solution the resulting precipitate. The same caution applies to alcoholic drinks. As the experiments have shown that active efforts increase or even induce the convulsions in strychnia poisoning, every care in treating the accident must be taken to avoid all such movements or any powerful stimulation.—'Zeitschrift der Aerzte zu Wien, No. 9, and 'Medical Times and Gazette."

HOUR-GLASS CONTRACTION OF THE STOMACH.

Ann Gallagher, æt. 40, a patient in the Pennsylvania Hospital, died April 22nd, 1860, of phthisis.

Post-mortem Examination ten hours after death.—Rigor mortis well marked. Upon opening the chest, pleuritic adhesions were found on both sides. In the right lung were large masses of softened tubercle, and an abscess in the lower lobe. At the apex of the left lung was found a large cavity communicating with two or three smaller ones, with tubercles scattered through the lower part of the lung. Upon the external surface of the heart were two large patches of lymph, but not adherent to the pericardium, and no signs of inflammation of that membrane; valves of the heart healthy. On opening the abdomen, the stomach was found very much enlarged, with the pyloric extremity extending below the umbilicus, and presenting a distinct hour-glass contraction, at about one-third the distance from the pylorus. The duodenum was doubled upon itself, and situated behind the constricted portion of the stomach. On attempting to pass a stream of water from the stomach through the pyloric orifice it passed very slowly, and on opening the stomach, found the pyloric valve very much thickened and constricted—the opening being only about one-fourth of an inch in

diameter. The liver and kidneys healthy. The patient had presented no symptoms which would have directed particular attention to the stomach while in the hospital.—'Amer. Jour. of Med.'

ACTION OF NICOTINE ON THE HEART.

Nicotine, M. Rouget observes, is regarded as possessing in the highest degree the property of rapidly destroying muscular irritability. The action of this poison on the heart presents a remarkable exception to this opinion. In frogs killed by the application of a drop of solution of nicotine to the eye or under the skin, the beatings of the heart continue long after all trace of irritability has disappeared in the muscles of locomotion. When the action of the heart has become feeble and the intervals between the beats increased, the direct application of nicotine instantly revives the contractions: these are at first notably increased in intensity, and at last become permanent, leaving the ventricle in a state of tonic spasm, with its cavity completely effaced. In birds and mammalia killed by the inhalation of chloroform, the ventricles remain fixed in the state of diastole; the right auricle alone manifests some feeble tremulous movements. If the ventricles be pricked or galvanized, no result is produced, or only some feeble and entirely local contractions take place. But, in this state, the contact of a drop of concentrated solution of nicotine produces general contraction, energetic response to the stimulus of pricking or the electric current, and finally permanent contraction.—'Journal de la Physiologie' and 'British Medical Journal.'

CASES ILLUSTRATIVE OF THE EFFICACY OF SESQUICHLORIDE OF IRON IN HÆMORRHAGE.

Dr Foucart says:—The Memoir of M. Pize, of Montélimart, has of late engaged so large a share of public attention, that I venture to forward to you a brief account of three cases of purpura hæmorrhagica in which sesquichloride of iron, exhibited internally, yielded what I am inclined to consider very conclusive results.

A woman, aged twenty-two, who had been confined a month before, presented, when I first saw her, the symptoms of typhoid fever, which had apparently lasted about twenty days. The patient was entirely colourless, and I was informed that she passed four or five times a day, with serous motions, a large quantity of frothy blood. I moreover observed on the body and on the limbs numerous purple spots, some of which were equal in size to a pea. Debility was excessive, and the pulse frequent and feeble. Under these unfavourable circumstances, I prescribed strong soup, wine-and-water, a decoction of bark, a four-ounce mixture containing twenty-five drops of the sesquichloride, and three small enemas daily, to each of which were added ten drops of the same remedy.

This treatment was readily borne by the stomach; the hæmorrhage gradually decreased on the two first days, and was completely checked on the third. The spots at the same time faded, turned lilac, and soon vanished altogether. On the eighth day convalescence was fully established.

Another woman, aged forty, had reached the fifteenth day of an apparently mild typhoid fever, when she was attacked with purpura and with vomiting of blood, which recurred five or six times a day. The same treatment was instituted, with the same favourable result as in the former case. In this instance, however, as the medicine seemed to induce some amount of gastric irritation, I caused it to be diluted in a quart of fluid, and in this manner it ceased to occasion any further inconvenience.

The third case refers to a woman aged twenty, who summoned me for an epistaxis which had lasted eight hours without interruption. On my arrival I found the patient bloodless, and threatened with syncope whenever she was placed in a sitting attitude. The entire body was covered with broad confluent spots of purpura and extensive patches of ecchymosis. I hastened to plug the nostril from which the blood escaped, with lints impregnated with a diluted solution of sesquichloride of iron, and prescribed a four-ounce mixture containing twenty-five drops of the undiluted sesquichloride. These measures at once checked the hæmorrhage. Forty-eight hours after, the patient was still much exhausted, and complained of sore-throat. On examination of the fauces, I found both tonsils covered with diphtheritic exudations, which the blood had concealed from my sight on the occasion of my first visit. The breath was fetid, and I feared the case must terminate fatally, diphtheria having for two years prevailed in the neighbourhood, and having in every instance proved fatal, within the scope of my personal observation, when complicated with purpura, attended or not by hæmorrhage. I nevertheless persevered in the exhibition of tonics and of the sesquichloride, which I likewise used locally as a caustic application to the diphtheritic patches, which had gradually invaded almost the entire surface of the pharynx. My efforts were rewarded by the most complete success, and after a fortnight of persevering attention I had the satisfaction of seeing my patient out of danger, and merely suffering from the local paralysis so common in such cases.

During the last of the three years that the epidemic above alluded to continued to rage, I used almost exclusively the sesquichloride as a local caustic; and in serious cases I exhibited ten drops daily internally, as a preservative from purpura and from hæmorrhage,—a frequent complication, and always the forerunner of certain death. This prophylactic medication appears to me to have rendered the occurrence of purpura more rare, and at any rate, from the time I adopted the method, the mortality was considerably lessened.—'Journal of Practical Medicine and Surgery.'

ON PHOSPHATED BREAD.

Professor Horsford, of Philadelphia, says:—Among the essential qualities of a substitute for cream of tartar, in the preparations of all forms of light bread, cakes and pastry, are that the article should be at least as unobjectionable as cream of tartar in its relations to the animal economy; that it should be pulverulent; and that when mixed with bicarbonate of soda and flour, it should, on the addition of moisture or application of heat, yield a neutral salt, and set free carbonic acid. If, in addition to these qualities, an article could be devised which should possess, in the form in which it is used, unquestionable excellence as an element of food, its value would be placed beyond doubt. I tried in a great variety of ways, as numerous others have tried, without success, to find some form of muriatic acid which could be mixed with bicarbonate of soda, so as, after raising the dough or paste, common salt should be found in the product. To this most desirable end insuperable difficulties presented themselves. I sought some form of harmless organic acid, suited to all the conditions of the problem; but this effort and many others were alike fruitless. At length it occurred to me to find, if possible, an acid constituent present in all the cereals and healthful food, and place this in the necessary conditions to fulfil the wants of the problem, and, at the same time, in such form that when taken into the system it would be suited to the agencies there in action, to be absorbed if needed, or readily and healthfully removed if not required. Of all such constituents on one is so important as phosphoric acid. Physiological and chemical researches have shown that wherever in the body there is an organ of important functions, there Nature has provided a store of phosphates. They are present in the juices, the tissues, the muscles, and in large measure in all the brain and nervous matter, and in larger measure still in the bones. The grains we consume contain them. The flesh we eat contains them. The bones we boil and dissolve contain them. All these considerations led me to the conviction that if it were possible to prepare phosphoric acid, in some form of acid phosphate of lime, such that, after its action with moist carbonate of soda, it would leave phosphate of soda (a constituent of the blood) and phosphate of lime (an essential constituent of food), and confer upon it the necessary qualities of a dry, pulverulent acid, the end would be so far attained as to justify a practical experiment in domestic use.

I succeeded in producing the article in condition to meet the wants of the problem. I then introduced it into my family for use in all forms, as a substitute for cream of tartar for culinary purposes. When many months of daily use had assured me that my theoretical views were sustained by practical application, I gave it into the hands of friends, whose prolonged experience fully confirmed my own. It has been in constant use in my family now for more than four years; and in the form of yeast powder during this time, it has been produced and consumed in all parts of the country to a very large extent, settling, in the most satisfactory manner, all questions as to its serviceability and healthfulness. Dr Samuel Jackson, professor of the Institute of Medicine in the University of Pennsylvania, gives the following testimonial in support of these views:—

"Your substitute for cream of tartar for the raising of bread is a decided improvement. The tartaric acid is not a constituent of the grains from which flour is made; it is not a nutritive principle, and often disagrees with the alimentary organs. The phosphate of lime, which is the principal ingredient of your preparation, is an essential constituent of all grains. It is further an important nutritive principle; and recent experiments have proved it is an indispensable element in the construction, not of bones only, but of all the animal tissues. A deficiency of the phosphate of lime in food is a common cause of ill health, of defective development and retarded growth in children. In the conversion of wheat into flour, the phosphate of lime is rejected with the bran; and, in consequence, this necessary element of nutrition, contrary to the arrangement of Nature, is not obtained from our fine wheat bread. Your preparation, while it makes a light, sweet, and palate able bread, restores to it the phosphate of lime which has been separated from the flour, and thus adapts it as an aliment for the maintenance of a healthy state of the organisation."—'Scientific American and Chemical News.'

BROMIDROSIS LOCALIS, OR FŒTID PERSPIRATION OF THE FEET.

In 'L'Union Médicale,' a M. Gaffard proposes the following remedy for "fœtid sweating of the feet." Red oxide of lead, one part to twenty-nine parts of the liquor of the subacetate of lead; the first to be bruised in a porcelain mortar, and the liquor gradually added. A few drops to be applied once a week, or oftener, in summer. Possibly there may be those who believe in the popular idea that the perspiration excreted on the feet is not inodorous. Professor Hebra of Vienna, in his lectures on the anatomy and physiology of the skin, has spoken of this notion, which is current in Germany. In connection with M. Gafford's proposed remedy for an evil which certainly does not exist, it may be of interest to quote Prof. Hebra's remarks, which I translate from the notes of his lectures published in the 'Allgemeine Wiener Medizinishe Zeitung' for 1857.

Speaking of the secretion of the perspiration, he says:—"There is no doubt that the sweat glands play an important part in the animal economy. Unfortunately, their physiological, and, still more, their pathological relations are but slightly understood. In general, we know that the secretion of sweat is very copious after hard work or continued bodily exertion, especially in the heat; and further, that it is under the influence of the nervous system. The sweat is colourless, soft to the taste, has a weak acid reaction and a peculiar smell. It can scarcely be denied that every individual disseminates a peculiar specific odour. This is proved by dogs following their master's track, and finding him by the help of their greatly-developed organ of smell. Our organ of smell does not possess the necessary development to enable us to determine such differences. But there are individuals whose peculiar penetrating odour can be easily recognized by every one. It is a great mistake to attribute such a disagreeable smell to the sweat alone. We must ascribe it to the secretion of the sebaceous glands. We may be convinced of this by simply examining an individual, the excretions of whose skin have a bad odour. On the palm of the hand, where there are only sweat glands, we shall not find any unpleasant smell; it will, on the contrary, be strong on those parts of the body where the sebaceous glands are numerous, as the back, and more particularly in the arm-pits. It is moreover certain that the smell does not come immediately from the fresh secretion, but that it exists after this has decomposed. The fresh secretion has either none, or else a slight odour of rancid fat.' But if the sweat remains some time in contact with the skin, it undergoes a chemical change, and then the disagreeable smell will be perceived. We will enter more particularly into this subject when we speak of the 'fœtid foot sweat,' which long ago was considered to be a materia peccans whose elimination from the body was desirable, and with whose healthy excretion no therapeutical interference was allowable."

"We come now to speak of a subject upon which similar erroneous views still exist. It is the so-called 'fœtid foot sweat' (bromidrosis). We have already said that the sweat, when secreted, has no bad odour. Hence it comes that persons troubled with this 'fœtid foot sweat' have no disagreeable odour on the palms of their hands, no matter if the perspiration trickles from them. And when the feet are carefully and properly cleansed (together with the toes and nails), they lose the highly-penetrating smell when they again begin to perspire. This so-called bromidrosis localis is found most frequently in young people who neglect proper cleanliness, and who possess no superfluity of covering for the feet, so that this is seldom changed. Hence, by the decomposition of the collected sweat, free fat acids are formed that have a disagreeable odour. These are absorbed by the pores of the leather, and one can easily convince himself, through his sense of smell, that the boots are the seat of the odour. Persons wearing a light covering for the feet, and often changing it, will have little trouble from 'fœtid foot sweat.' Hence this seldom occurs in the female sex, although the perspiration is more copious in women. As, from what has been said, it is evident that we have to deal rather with 'stinking boots' than 'fœtid foot sweat,' the absurd ideas which are in circulation as to the evil effects of suppressing, or too quickly checking the sweating of the feet, must be entirely given up. On other parts of the body also, where the secretion has an opportunity to remain some time in contact with the surface of the skin—*e.g.*, in the arm-pits, on the scrotum, perineum, &c.,—a similar decomposition of the sweat takes place, and a very disagreeable odour is created. The treatment of this 'fœtid sweating of the feet' is therefore reduced to ordering greater attention to the cleanliness of the skin, and a more frequent changing of the covering of the feet."—Dr Jeffries in 'Boston Medical and Surgical Journal.'

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Untamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

THE MEDICAL CIRCULAR.

WEDNESDAY, OCTOBER 17, 1860.

CRIME, DISEASE, AND THE POOR-RATES.

In the numerous articles that have appeared in this Journal on the subject of a reform of the Poor-laws and the sanitary condition of the humbler classes, we have refrained from regarding these topics from a point of view which is nevertheless of great importance to the statesman and the philanthropist: we mean that which is embraced in the proposition of an equitable assessment of the Poor-rate upon a uniform valuation of property over extensive areas. Having been in the habit of considering this proposal as a part of the high policy of the kingdom, rather than a necessary condition of the settlement of those questions which usually come under our province, we have hitherto put it aside; but having recently perused a pamphlet, by Mr Gilbert, a member of our Profession, giving an account of the proceedings of the Metropolitan and County Association for the Equalization of the Poor-rate, and containing many remarkable disclosures of the misery and suffering among the poor which are attributable solely to the present unjust method of levying the Rate, we think that we shall be doing useful service to those interests which it is our duty to promote, by calling attention to the objects this Association is desirous of accomplishing.

Any observant person whose duties lead him to association with the poor, must know that a considerable portion of their destitution and suffering is caused by the wretchedness of their homes, the overcrowded manner in which they huddle together, and the small modicum of relief which the Boards of Guardians presiding over those deeply-impoverished districts are able to afford. There is an antagonism between riches and wealth, which is fostered, if not created, by the conditions of our urban civilisation. The mansion and the hovel cannot abide together; broadcloth and fustian admit of no companionship; and, moreover, the enhancement of the value of land, caused by the congregation of the porticoes of the opulent, makes the emigration of the poor to remoter districts a financial necessity: hence arise the trenchant separation of classes, which is one of the most marked and painful characteristics of our large towns, and that estrangement of sympathy which is its natural result.

In consequence of this segregation of the poor, and their exclusion from higher social influences, vice and crime develop among them with wondrous energy and rapidity. We are informed that the diseases arising from immorality increase in number in proportion as the poor are crowded together, and that theft and other crimes are more frequent as the poverty of the locality is the greater.

The increase of wealth, the needs of commerce, the ambition of life, and the all-pervading selfishness of human nature, which prompts every man to seek his own comfort even at the expense, if necessary, of his neighbours, cause a precipitation of poverty into the lowest and filthiest quarters of our Metropolis. The dregs of society are thus continually falling, and are set aside as of little consideration. In the City of London Union, where, owing to the erection of numerous gigantic warehouses to meet the requirements of trade, there has been a remarkable decomposition of its population, the poor have been either driven away, or compressed into courts and alleys, where existence is maintained in defiance of natural laws. Life is here, indeed, a battle. There are now in the City ten thousand fewer of the working classes than there were in the year 1801; although, in all probability, the number of working men employed in the docks and warehouses, which make the opulence of the City, is ten times greater now than it was then. In the neighbouring district of Whitechapel, the population, consisting chiefly of the operative classes, has been increased by more than ten thousand persons, notwithstanding that more than seventeen hundred houses have been removed. We might travel through the Metropolis and tabulate its population statistics in a similar way: it is sufficient, however, to point to the palaces of Belgravia and Tyburnia, the mansions of Clapham and the Regent's Park, and the warehouses of the City, in contrast with the attics of Holborn, the narrow lanes of Shoreditch, and the back alleys of Westminster and the Borough, to illustrate our argument. There is one fact, however, in connection with this question which we must not omit, as it brings the whole argument into a focus, and exhibits it in the most striking light. Mr Gilbert is our authority for stating that in two neighbouring districts, one of which was inhabited by the employers, the other by the employed, the Poor-rate, during four years of distress, fell in the former from 730*l.* to 700*l.*, and rose in the other from 17,507*l.* to 29,299*l.* A large proportion of this increase was paid by persons not much above the condition of paupers themselves. We need not ask the reader to imagine the amount of induced disease and crime these latter figures represent.

The Association to which we have referred maintains that an equalized Poor-rate would, whilst not pressing heavily upon any district, materially lighten the burden upon the most impoverished, and eminently improve the condition of the poor. One effect of this proposed change adverted to by Mr Gilbert is so important in itself, and has so interesting a bearing on Medical sanitary questions, that we cannot forbear to quote Mr Gilbert's words. He says:

"One great advantage of the system of equal rating for the relief of the poor over the entire surface of counties would be the possibility of assisting in any great public movement or work for the relief or benefit of the poor at a comparatively trifling cost to the rate-payer. For example, let us first take the medical care of the poor. In a case of severe epidemic, or scourge of Heaven, such as the cholera, a rate of sixpence in the pound over the area of Wiltshire would yield sufficient for the maintenance of a thousand hospital beds at the average expenditure of the Westminster Hospital for nine months. A penny rate over the Metropolis would yield sufficient to maintain a thousand hospital beds at the working expenditure of St George's Hospital for twelve months, leaving two thousand pounds for the salaries of the medical officers, and a surplus of ten thousand pounds for a Samaritan fund for the sufferers. The maintenance and relief of the sick poor is a subject which by no means receives from the Legislature the amount of consideration which is due to it. It does not appear to be considered that disease engenders disease, and that in cities and large towns a very large proportion of the poor's-rate is caused by sickness. In the parish of Wandsworth, near London, it was proved by Dr Nicolas, the medical officer of health for the district, that fifty-eight per cent. of the poor'e-rate in his neighbourhood was caused by sickness. In Kensington sixty-four per cent. of the diseases of the poor are from preventable causes. In the poorer parishes this is especially the case. By the Registrar-General's report (1857) it appears that in the parish of Bermondsey the proportion of deaths from typhus and all other causes was as one to seventeen. The amount of expenditure this must have caused must have made considerable addition to the poor-rate, especially as a large proportion of the sufferers were parents of families. To understand this effect the better, let these deaths from typhus be compared with those from the same cause in another parish, say Marylebone, where during the same year the deaths from the same cause were only as one to fifty-seven. Under a system of county-rating, its whole sick poor might be placed under one organised staff, and the expenditure would be but trifling, while the sanitary effect on the population would be of the most beneficial description, if the medical officers were but chosen for their skill and humanity."

The view thus opened by Mr Gilbert is highly significant of the advantages that would accrue from a more liberal and comprehensive system of Poor-law Administration. When we remember that all the Hospitals that are supported by voluntary contributions are in debt, and that some of them are obliged to close their wards from want of funds; when we remember also the small amount that is contributed towards their support by the aristocracy and the opulent classes residing near those institutions,—we cannot refrain from indulging a hope that some means may be adopted of extracting from the resources of the rich a larger proportion in aid of the necessities of the poor

than they now subscribe. This inequality of taxation for the support of the poor is the great blot of the system, and the parent of much vice, crime, and disease. It is time that our legislators turned their attention to this subject; for, if we mistake not, there is a growing feeling in the Metropolis that the present condition of things is too unjust and baneful to be long continued.

SUMMARY OF THE WEEK.

INSANITY IN ENGLAND AND WALES.

Among the physiological problems which men take an interest in discussing, is that relating to the influence of our modern civilisation in the production of insanity. It is generally concluded that since the competition of life has grown so intense in this country, insanity has increased in a marked degree; and the evidence of this position is drawn from the large number of persons now confined in our numerous Asylums. In order, however, to appreciate the value of this evidence, the increased facilities which such establishments afford of providing for the insane, and thus withdrawing them from the privacy of domestic life, must be borne in mind. Insanity can be now subjected to statistics, which was not the case half a century ago. A return of Pauper Lunatics recently published throws some light on this question. We find that there are in England and Wales 31,543 insane paupers, of whom 22,378 are lunatics and 9,165 idiots—that is to say, about two-thirds of the whole number are lunatics, and one-third idiots; but it is remarkable that this proportion does not prevail in every district of the country. There is more idiocy in the southern counties than in the north; and in Wales so many as one-half of the insane are idiots. The same proportion holds good in the south-eastern and south-western counties of England. The same report informs us that three Welsh counties — viz., Cardigan, Carnarvon, and Denbigh — present double the number of pauper idiots returned for Manchester, but one-third the number of pauper lunatics. It is therefore obvious, that the more the faculties of the mind are developed by the ambitions and struggles of life, and by all those agencies, such as education and moral culture, which are necessary to fulfil the design of a high condition of civilisation, the higher is the standard of mental power, and, consequently, the less idiocy. But, on the other hand, lunacy, or a break-down of the intellect, coincides with a general increase of its power. We do not think, however, that the question is determined, whether, in the aggregate, insanity is increased or diminished by civilisation,—whether, indeed, the raising of the idiot portion of the community to a sane condition, caused by a gradual improvement of the race, does not more than compensate for the deprivation of intellect by lunacy. Then, again, it would be interesting to know to what extent the lunatic members of the community are derived from those stocks which have been improved from the idiotic state, but were still unequal to the strain of a competitive state of society. These problems, which involve important psychological and social questions, might be answered by any man who would undertake the duty of analysis.

DISINFECTION OF TOWN-SEWAGE.

If the accounts that have reached us be reliable, the problem of the possibility of the disinfection of town-sewage at a moderate expense has been solved, the agent being carbolic acid. We know that there are many agents that will produce the same result; but exceptions have been taken to their use, either on account of their expensiveness, their deterioration of the sewage as a manure, or their poisonous qualities. An experiment has now been carried out at Carlisle, by which the sewage of that town has been completely disinfected by carbolic acid, and afterwards employed as a manure upon the adjacent lands. It is stated by Dr Angus Smith, that the sewage is thus rendered perfectly inodorous. The entire cost of disinfecting the sewage of this town is 95*l.* per annum, exclusive of the cost of erecting the works, which was 400*l.* This attempt has been made by Mr M'Dougall, who has taken a lease of the sewage of Carlisle and adjoining fields for the purpose of effectually testing the project. Supposing that further examination should confirm the accuracy of the statements now made, there will be no great difficulty in future in disinfecting the sewage of all our towns and villages, and putting the sewage to a practical use.

HOPE FOR THE HOSPITALS.

We have lamented in another article the disheartening pecuniary condition of most of our large hospitals, but we are now pleased to say that a Mr Bond, who is a member of the Jockey Club, has thrown out a suggestion which will, no doubt, cause the hearts of hospital treasurers exceedingly to rejoice. He proposes that ten per cent. should be annually allotted from the Derby and Oaks stakes, which would make a sum that he calculates at 900*l.*, in aid of a fund for the permanent endowment of the following hospitals:—St George's, St Mary's, King's College, Charing cross, the London and the Royal Free;—the Middlesex and the Westminster, and a fry of smaller institutions, being omitted from the category. This is one of the best modes in which such gains could be appropriated. Mr Bond has generously offered to lay down a sum on his own account to form the basis of the fund.

MEDICAL REMUNERATION IN RATHDOWNEY.

On the election of Dr Smith to the appointment of Medical Officer of the Rathdowney Dispensary in Ireland—an appointment which is equivalent to that of Union Surgeon in this country—there was an attempt made by the Board to induce the candidate to agree to receive a fee of five shillings for a visit to such of his patients as were not entitled to a ticket for medical relief. As a matter of principle, Dr Smith was justified in refusing to assent to such a proposition: it was a bargain which the Board had no authority or right to enter into, and, if made, could not have been legally binding. But when Dr Smith objected that it would be derogatory to his College to take a smaller fee than a guinea for his visit, w could but wish that such a beneficent rul was instituted in this country in behalf of its Poor-law Doctors. How many a Union Surgeon's mouth must water at the idea of his getting a guinea a visit from all the independent labourers and small shopkeepers of his hamlet! What happy times there would be for the Doctors throughout the country, if this principle of payment could be realised! When Dr Smith triumphantly remarked that it would be worth a person's while, when he fell sick, to go to London to be attended for a fee of five shillings, we could but agree with him; for if the illness were a long one, he might save his travelling expenses out of his fees. We advise the Dispensary Surgeons, however, not to acquaint their patients with this fact. The Surgeons in Ireland may fully expect, after this announcement, a large emigration of British Practitioners, who will be too eager to participate in the profits of such a Professional California.

REVIEWS.

A Practical Treatise on the Diseases of the Urinary and Generative Organs (in both Sexes). Illustrated with Woodcuts and Coloured Plates. By Wm. Acton. 3rd Edition.

Mr Acton has divided his book into two parts, in the first of which he treats of Non-Specific Diseases; in the second, of Specific Diseases. Under the section of Non-Specific Diseases, the Author treats of Blennorrhagia, Gonorrhœa, Stricture, Prostatic Disease, Epididymitis, Hydrocele, Inflammation of Bladder, Incontinence of Urine, the various forms of Blennorrhagia in Women, and Herpes Excoriations, Pruritus, together with the numerous modifications and *nuances* of the several affections here enumerated. Under the head of Specific Diseases, the Author treats of Syphilis in its various stages and constitutional conditions.

Mr Acton's Treatise is so well known, and has so meritoriously taken its place as the highest authority in our language upon the diseases which have occupied the writer's attention, that we shall not extend our analysis into the several divisions of the work, but shall confine ourselves to a notice of those portions which have been added to this edition, or in which the Author has deemed it necessary to make alterations in order to keep his work abreast of the advancing tide of science. The

questions he has especially discussed in this edition are:—whether there is more than one virus capable of producing specific disease, the real significance of induration, the microscopical appearances of gummata and tertiary symptoms, and the latest views on the subject of rape. He has also given additional tables on the mortality of syphilis, &c.

In arguing the question of the plurality of poisons, the Author first sets forth the conditions of contamination. In these points he follows Ricord. He says that simple sores produce simple sores in other individuals; and that indurated chancres will produce, as a rule, indurated chancres. Exceptions are admitted. He observes, "In fifty-nine instances collected by M. Ricord's Interne, and confirmed by him as well as by his colleagues, it appears that the origin of indurated chancre was traced to indurated chancre—*at least when the contagion was transmitted to a constitution that had not been previously affected with constitutional syphilis.* If the patient have had previously an indurated chancre followed by secondary symptoms, a second infection from an indurated chancre will produce a *soft* chancre. Again, this *soft* chancre will produce an indurated chancre in the instance of a person who has never had syphilis.

The indication, therefore, is that indurated chancre does not arise from a distinct virus, and that the modifications of the sore depend upon the condition of the patient.

With reference to the question of the plurality of viri, Mr Acton quotes the guarded opinion of M. Ricord, as expressed in a recent lecture, to the effect that even though future research should establish the truth of a plurality of poisons, it would not subvert the principle of the unity of syphilis. It would only prove that there was by the side of syphilis another and foreign affection, resembling it in mode of attack and external symptoms, but differing from it in not exercising any infecting influence on the economy. Mr Acton's opinion is, as given above, that there is but one poison, but differing in its effects according to the idiosyncrasies or diathesis of the constitution into which it is introduced.

The Author gives an excellent description of indurated chancre, but we do not conceive it expedient to reproduce a part of it; and to give the whole would occupy too much space. The microscopical characters of gummata are described at length. These gummata are tubercles of the cellular tissue, and are the characteristic signs of the tertiary stage. They are found in the sub-cutaneous and the sub-mucous cellular tissue, or wherever this conjunctive tissue exists. These tumours never appear before the fifth month after contagion, and may come on after thirty or forty years have elapsed. Mr Acton quotes M. Ricord, who says of this affection; "It mostly begins with a hard kernel of a small size, situated in the deeper layers of the skin: it grows very slowly; so much so, that I am not quite sure of the size it may reach; but this development takes place without any local or general reaction, and in the cases I have observed the tumour seldom exceeded the size of a walnut, and mostly remained much smaller. These tubercles or elastic tumours are not confluent; and this fact is sufficient to establish a distinction between them and molluscum, which, generally, is remarkably confluent." These tumours have been observed in the testicle, the brain, the lungs, and other parts. Again, M. Ricord says, "As the syphilitic tubercle grows, it becomes rather painful: this is almost always owing to inflammation set up within it. Before this complication occurs, it lies quite free in the cellular tissue, and adheres to the skin only at one point; but when inflammation sets in, it gets confounded with the surrounding tissues, its mobility is lost, the skin covering it becomes red, swells, softens, and ulcerates on one or several spots, and a deep ulcer follows the plenteous discharge of purulent matter. The edges of the sore become undermined, and the neighbouring parts are involved in a destruction which varies according to the organs whereon the tumour has settled." Microscopically, this disease is due to a cell-formation analogous to granulations.

It is with much satisfaction we recommend this Treatise to the notice of our readers. It treats with lucidity and completeness the various topics incident to this most important department of surgery; it is furnished with a large number of very beautiful coloured illustrations, and is in every respect admirably got up. No surgeon can boast of a well-furnished library who is without this Treatise.

A Short Notice and Description of various New and Improved Surgical Apparatus, Trusses, &c., Invented and Manufactured by Thomas Eagland, Leeds.

We have often thought that a concise account of the mechanical aids used for the relief or cure of disease would be useful to Medical Practitioners. Mr Eagland, a Surgical Mechanician of Leeds, has thus provided us with a description of those instruments in the manufacture of which he has exercised his ingenuity. Here are instruments for spinal curvature, distortion of the limbs, prolapsus of the rectum, hæmorrhoids, prolapsus of the uterus, and hernia. The merit of these instruments is their simplicity, and we are glad to find that they have received the approbation of some of the most eminent Members of the Profession.

Some Points in support of our Belief in the Permanance of Species, and on the very limited Application of the Doctrine of their Origin by Natural Selection. By Lionel S. Beale, M.B.

This pamphlet took its rise from a discussion on the subject at the last meeting of the British Association. The Author is opposed to the Darwinian theory, as incomplete, unsustained by an adequate number of facts, and inconclusive. Dr Beale thus states Dr Darwin's theory:

"The theory does not suppose, like some which have preceded it, that species and genera of animals pass, in the course of successive generations, into other forms; but that certain individuals of a race, being exposed to circumstances different to the general mass, will in consequence become somewhat altered. Their habits and instincts are supposed to become modified, and their structure adapted to suit the new conditions under which they exist. If these conditions were unfavourable, they would soon die out; if favourable, the creatures would, in the course of successive generations, undergo still greater modifications, until there was little resemblance to be traced between them and their original progenitors. The latter, in some cases, would disappear altogether, in others would retrograde, and, in some instances, might be supposed to retain for a time their original type, destined perhaps at length to undergo a different order of changes, in consequence of being exposed to different external conditions."

He thus delivers his answer:

"Many believe that the modifications which occur under altered external conditions are more limited in their extent and more subordinate in their nature than the advocates of this theory suppose. That even man is influenced by temperature, food, habits, clothing, no one will deny; but whether these influences, acting through any amount of time, would be capable of producing anything but an altered man, is quite another matter. Wonderful indeed are the differences observed in the physical, mental, and moral conditions of various races of men, and among tribes and individuals of a race; but yet all are men, and distinguished from every other creature by essential differences, infinitely greater than the non-essential and more subordinate characters which distingnish these tribes and individuals from each other.

"As man is affected by external conditions, every living thing below him is also affected, but in a very much greater degree. Plants are modified to a far greater extent than animals, animals than man. Varieties are most easily produced in plants, and without great difficulty in some animals: the animals which are most under our influence being those in which the greatest modifications are produced; but these are still only subordinate modifications. Look at the endless varieties of dogs, and the comparatively slight differences observed among successive generations of cats. How soon, too, the cat reassumes its wild state, compared with the dog! Yet, through all the varieties of dogs, there has never been produced a generation of wolves or foxes. Every variety of dog looked at as a whole, considered with reference to his habits, form, instincts, and his whole being, is still but a dog; so it is with goats, sheep, oxen, pigs, pigeons, fowls, canary birds, &c.

"In the lower animals, it is more difficult to point out specific differences than in the higher, in plants more difficult still. The more simple the organised body, the more likely will it be that it will be much altered by external conditions, the more inconsistent will be its characters, and the more difficult will it be to assign to it its exact specific peculiarities. It must be borne in mind that, among the higher animals, and even in man, there are certain subordinate points which perhaps may be roughly compared to the colour and form of petals or leaves in plants, which are readily affected by external circumstances. But these changes are, as far as has yet been proved, *limited*. To assign the exact limit in the present state of knowledge is very difficult, and perhaps quite impossible. It may, however, be remarked, that in the vegetable kingdom it is only certain allied plants that can be propagated by grafting, and among animals there is no race of true hybrids. A plant becomes very greatly modified, an animal in some important particulars, a man in comparatively very slight degree, the alterations affecting only the size of his limbs, colour, and texture of his skin, hair, &c."

Dr Beale makes a just observation when he remarks that all divisions into species are arbitrary and artificial, and hence cause much of the confusion which furnishes the excuse for new theories. One of the principal series of facts which gives a colour to the Darwinian and and allied theories of development Dr Beale comments upon in the following words:

"Lately it has been demonstrated, not in one solitary instance, but in a vast number of cases occurring in different classes of animals, that creatures, so to say, belong to different groups at various periods of their existence, before their specific form is attained. In other words, the offspring of certain creatures are imperfectly formed and unlike their parents. These larval forms are capable of producing larvæ like themselves, or other imperfect forms somewhat differing from their immediate non-sexual parent. This process often goes on to the production of millions of still imperfect creatures, until at last these produce forms totally unlike themselves,—perfect, sexual, and with all the characters of the two original parents of this unnumbered progeny.

"These millions of creatures result, then, from one single ovum. In many cases, in the different stages through which the larval forms pass, they live in different media, consume different kinds of food, and are exposed to different external circumstances.

"But can it be maintained that external agencies are alone concerned in producing this wonderfully exceptional mode of multiplication, which seems so perfect a plan to ensure the development of a vast number of distinct creatures of the same species within an incredibly short space of time, in spite of their being exposed in each phase of existence to many different chances of destruction—can such facts as these be explained except as resulting from infinite wisdom and design?"

Dr Beale has treated the subject in a cautious and philosophic spirit.

The Reformed Roman or Oriental Baths. By James Tucker, M.D.

In this little *brochure* Dr Tucker has given an interesting account of the Roman Bath. Our readers being well acquainted with the

subject from the various letters that have appeared in this Journal from the Author's pen, we do not deem it requisite to dilate further upon the subject in these columns. Dr Tucker is benefiting humanity by his efforts to extend the practice of bathing among the people.

A Case of Homicidal Mania, without Disorder of the Intellect. By C. Lockhart Robertson, M.B.

Homicidal Mania is a subject of such deep interest to society generally, and particularly in relation to a just fulfilment of the law, that we are glad of any correctly-reported facts bearing upon it. We have on former occasions pointed out the danger of a too easy adoption of this view of the mental state in criminal cases; but if all cases were so plain and remarkable as that recorded by Dr Robertson, there would not be much necessity for caution. This man had been sent from the Kent Asylum to Dr Robertson with a very bad character, he having attempted several times to injure persons in that asylum. When he came under Dr Robertson's care, his intellect appeared sound, certain delusions under which he had formerly laboured having disappeared. Dr Lockhart thought he had recovered also from his homicidal propensities; but, to his surprise, one day he made a fierce attack upon Mr Gwynne, the assistant Medical Officer.

Dr Lockhart thus comments upon the case:

"From the time of his attempt on Mr Gwynne until the date of his removal, he was constantly seeking for an opportunity to renew his attack. His countenance assumed a fierce expression, and his eye lighted up with the glare of a wild beast, when visited and spoken to either by Mr Gwynne or myself. As I said above, I did not give him another chance, but kept both his hands fastened in the ordinary police waist-belt during his stay here. Had that stay been prolonged to the day of his death, I should not, I think, have felt myself justified in authorising the entire removal of the restraint. When the intellect is affected by disease, the precautions suggested by experience enable us to deal with the various manifestations resulting from that disease; whereas in one of sound intellect, and hence able to plan and arrange future schemes, no precaution could at all times, in the crowded wards of a county asylum, and with the freedom and liberty allowed, protect the officials or patients from the sudden homicidal assaults of lunatics of the class under consideration.

"*Clinical Remarks on the Case.*—This case is instructive as showing how morbid action of the will leading (contrary even to the knowledge of the wrongness of the act) to attempts at homicide may exist in a mind apparently sane. I believe any jury would have convicted the patient of murder, had he been discharged from this asylum previous to committing the attempt. He was undoubtedly, as I have remarked above, conscious of right and wrong. No one could have expressed more fully, or more properly, his regret at the acts of violence he had committed at the Kent Asylum; his intention hereafter both to conduct himself better, and also to make what atonement he had in his power for the injury formerly done by him. He freely admitted that he was conscious of right and wrong, and that he should be made amenable to the law in the event of his renewing his homicidal attacks. And yet there can be no doubt that the attempt he did within a few days of this avowal make to destroy the life of Mr Gwynne was the act of a person of unsound mind. It was made without provocation; indeed, in return for unvarying kindness and attention. It was done before witnesses, and without the slightest chance of escape. He was in the airing court, where two attendants were on duty; and Mr Gwynne was accompanied by the head attendant at his visit. Even had he succeeded, he knew that such an act would certainly insure his prolonged detention here; and yet when I pressed these points in conversation with him afterwards, the only answer I got was that he would not injure the attendants, that he had an objection to medical officers, and that Mr Gwynne had had a fortunate escape. When told that the Secretary of State had decided on placing him in an asylum where he would enjoy less liberty and be subject to more restraint, he said he fully deserved it, that he had brought it upon himself, and that he acknowledged the forbearance with which I had treated him.

"The previous history of this case at once points to the existence of some deep-seated moral perversion, or lesion of the will more likely, or perhaps both, it is hard to say, from which these homicidal attempts resulted. There had been auditory illusions (one of the most intractable forms of partial insanity), and he had been the subject of delusions also, as is related by Dr Huxley in his history of the case. There had been violence and insane attempts to break glass and destroy property. These symptoms had, it is true, either been cured, or had passed into abeyance; but their result in the lesion of volition and perverted emotion which led to this homicidal attempt show how deep-seated the morbid mental action had become, and may serve as a warning of how the utmost caution and circumspection are necessary in discharging from the control of an asylum any case in which this homicidal mania has ever shown itself. Like a horse who has once reared, these cases are, in my opinion, never safe; and I should not sanction, under any circumstances, the entire restoration to liberty of any undoubted case of homicidal mania."

He was afterwards sent to Fisherton House, and there attacked one of the attendants with a short-pointed piece of wood (his usual weapon), with which he stabbed him about the head. There can be no doubt about a case of this kind: the doubt exists in the case of criminals where the history is not so clear and connected.

SKETCHES OF EMINENT PHYSICIANS AND SURGEONS
OF THE LAST CENTURY.
By JOSHUA BURGESS, M.D.

MEMOIR OF JOHN HUNTER, F.R.S.
(Concluded from page 247.)

In the summer of 1785 he had attacks of flying gout, was subject to faintings and heart affections, attended with great irritability, with some disturbance of the sensorium. This manifested itself in apprehension of hydrophobia, having been bitten by a dog at some earlier period. For these affections he first visited Bath, and afterwards Tunbridge Wells.

Sir E. Home entertained a high opinion of John Hunter's skill as an operator. To use Sir Astley Cooper's expression, he thought him neither "dexterous nor elegant." The latter phrase is derived from Sir Astley Cooper's day. Hunter would frequently say, "To perform an operation, is to mutilate a patient we cannot cure. Operations should, therefore, be considered acknowledgments of the imperfection of our art." "His large experience, and his extraordinary skill as an anatomist, almost always enabled him to complete any operation he undertook: though slow, he was sure." A contemporary biographer, speaking of him, says—"That he is fully entitled to the highest celebrity in both these departments (anatomy and surgery), it is impossible to dispute; but we may at the same time confidently affirm, that could his own voice have been heard, he never would have consented to rest his fame on any narrower basis than that afforded by his invaluable labours and his brilliant improvements in the wide field of natural science." (*a*) The study of anatomy and dissections, commenced for professional objects, was far too restricted for John Hunter's ambitious mind. He soon diverged from human to comparative anatomy, which led him into the vast field of natural history. Thus his labours and discoveries attracted first the notice of Baron Haller, who was then considered the first physiologist in Europe. Lord Brougham, at the inauguration of the statue of Newton, said that "Cuvier had been preceded by inquirers who took sound views of fossil osteology, amongst whom the truly original genius of Hunter fills the foremost place." His Lordship on that occasion reviewed the labours of "Buffon, Cuvier, De Blainville, Schilling, Müller, &c."

About this time he had accomplished the object of his life—completion of the arrangement of the Museum. He reduced the collection to a system, illustrating the functions and economy of animal life. The public were admitted, under certain regulations, to view the collection.

In 1789, he was admitted an M.R.C.S. of Ireland. A friend, Mr Sharp the engraver, persuaded him to sit to Sir Joshua Reynolds, who promised to take great pains with the painting, and said he would make it a test of his artistic abilities,—by it rather to obtain distinction and character, than to obtain reward by its sale. This was one of the last of Sir Joshua's works engraved by Sharp, and it is considered one of the most splendid heads and finest engravings in England. When Lavater was shown Sharp's celebrated engraving of the open countenance of John Hunter, he exclaimed, "That man thinks for himself!" Mr H. Weekes, A.R.A., is now engaged in the execution of a statue of him, proposed to be placed in the museum of the College. This, we think, is a strange artistical anachronism, when the lonely emblem of Jenner—his constant friend, early and late—is resting in a pensive attitude, melancholy for its mate. Close by, from St Martin's Church, was the dust of Hunter exhumed, when the bronze to commemorate Jenner was being reared. Their merits are so equal, their friendship in life so unalloyed and serene, what in this posthumous association will assort so well with the other, as an effigy of John Hunter?

In 1792, he relinquished his lectures to Home. On the death of his early patron, Mr Adair, he was appointed Inspector-General of Hospitals and Surgeon-General of the Army. These engagements took him from his usual pursuits. In short, his numerous appointments, honorary or otherwise, became so extensive, we cannot attempt an enumeration of them. He continued to publish, and amongst others we must name, 'The Treatment of Inflamed Veins,' 'Introsusception,' 'Observations on the Economy of Bees,' &c. &c. In the same year, he contributed his last paper to the 'Philosophical Transactions,' 'On the True Bee.' He cultivated this fondness for bees at Earl's Court, keeping his beehives in the conservatory. On relinquishing his lectures to Everard Home, he handed over all his manuscripts. These Home afterwards destroyed, and founded other lectures upon them. He frequently abused Home for his clumsy fingers, swearing that "his fingers were all thumbs," and that he would never have sense enough to tie down a bottle. On the other hand, he esteemed Sir Anthony Carlisle for skill in making preparations.

We are now approaching the termination of our memoir. Unfortunate dissensions sprang up, in consequence of rivalship in an election for the office of Surgeon to St George's Hospital. The contest was conducted with great and unprecedented warmth. Everard Home, Hunter's assistant-surgeon, lost the election by a decided majority. This circumstance rankled and embittered the feelings of John Hunter towards his colleagues. He manifested this rancorous disposition on every occasion. Unfortunately, he adopted extreme measures in carrying out his animosity, and they were thwarted. The Governors of the Hospital on more than one occasion decided adversely to his views. He was in opposition to all his colleagues, except Baillie. These feuds terminated only on his awfully sudden death. He had some time before been suffering from great agitation and anxiety, from a heavy and unexpected pecuniary loss. The symptoms evidently proceeded from some affection of the brain; and, in charity, we may attribute many of John Hunter's eccentricities to this source.

The disputes and contentions in which John Hunter was implicated with his colleagues at St George's, were of that frivolous and disparaging nature, that we can only allude to them as curious instances of the tastes and manners of the day. An indulgence in quarrels of the kind in our day would be at the sacrifice of so much self-respect as to subject parties indulging such propensities to become amenable to severe animadversion and criticism. John Hunter scarcely escapes the imputation of a mercenary motive; but we believe vanity to have been the ruling passion which was the source of so much irritation. He insisted upon his points with that pertinacity and ardour

(*a*) 'Naturalist's Library,' vol. x. 'Memoirs of John Hunter.'

which characterised the conduct of his life. The Board of Governors of the hospital had passed a regulation which required all who wished to offer themselves as candidates to become pupils, should have been educated to the Profession. Two young men came up from the country, ignorant of this regulation, and applied to be admitted under John Hunter. He undertook to plead for them at the Board: he expected opposition as a usual event. His state of health warned him of the risk when this discussion became imminent,—which, from intelligence he had received, was certain to occur. He foreboded the catastrophe which occurred, in an interview with Dr Richardson. The Board met on Oct. 16th, 1794. He left home in apparently high spirits, but somewhat excited. He left by accident on the study-table his case-list, which Mr Clift—who then resided with him—followed to restore to him. He found his carriage at the house of a patient in St James's street. Clift delivered the list to him, and heard him order the coachman, in an animated manner, to drive to the Hospital. He entered the board-room to fulfil his promise, and found it already assembled. He directly urged the propriety of these candidates being admitted. In the course of his remarks, he made some observation which one of his colleagues thought it necessary instantly and flatly to contradict. Hunter immediately ceased speaking, and, struggling to suppress the tumult of his passion, hurried into the adjoining room, which he had scarcely reached, when, with a deep groan, he fell lifeless in the arms of Dr Robertson, one of the physicians of the hospital, who chanced to be present. Dr Baillie had immediately followed him into the board-room. Mr Home was also present, and every attempt was made to restore life. "His body was placed in a sedan chair, and conveyed to Leicester square, followed by his now vacant carriage."

"John Hunter was of short stature, very strong, bodily active, and well formed, and capable of great exertion. His countenance was open, animated, and deeply impressed with thoughtfulness. Towards the close of life he was easily irritated, and not easily pacified when once provoked." A bust of him was made by Chantrey, taken from a mask Sir Joshua Reynolds had modelled between the intervals of his sittings while painting his portrait. This had been mislaid and forgotten, and was found amongst lumber after his death. "Soon after his death, Mrs Hunter felt anxious to erect a monument to his memory in Westminster Abbey. The fees demanded for permission to occupy a niche within that venerable fane were too great for her reduced fortune, and she therefore abandoned her intention." (*b*) John Hunter died in his sixty-fifth year. Our summary of the chequered incidents of this venerable man's life is imperfect and incomplete. To do them small justice, more ample space would be required. A temper of mind well toned for philosophical disquisition would be required to cursorily entertain the various topics which occupied the whole life and labours of John Hunter.

Health of the Armies in Syria, China, and Italy.—Intelligence respecting the health of the French soldiers in Syria is very unfavourable. Although they had not yet gone on any expedition, 600 men, or about one-tenth of the force, were in hospital. The English troops in China, on the other hand, are described as being in an excellent state of health; the hospital ships models of comfort and efficient arrangement, and general sanitary precautions carefully carried out. As a result, 12,000 men are now embarked for campaign in a state of health rivalling that of inhabitants of rural districts. Let us hope that we have at last an example of sanitary administration that will be consistently followed out. The bad economy of killing our soldiers by routine, in order to save our enemies the trouble, seems at last likely to be recognised.—From Italy, medical intelligence is also more favourable than heretofore. The dearth of medical stores is now nearly at an end. The hospitals are under the superintendence of Madame Mario, and are in many respects improved. The recent arrangements of the Medical Staff after the engagement at Capua are spoken of in terms of praise. It is in contemplation to establish a central hospital at Naples, and one also at Palermo. The organization of the Hospital Staff, however, leaves much to be desired.—'Lancet.'

HOSPITAL REPORTS.

KING'S COLLEGE.—Sept. 29th, 1860.

Cure of Hernia—Wood's Operation.

Having, in a late number (August 22nd), said so much in explanation of the details of this very curious operation, it would be scarcely necessary to go into the subject again. But the operation is not to be so cursorily treated. It will rarely be performed, but some new feature, and fresh anatomical phase, will present itself for notice. Two such singular cases have occurred at King's College lately, the first on this date, and the second on October 6th inst. Both these cases observed a strange similarity of eccentricity, and in relating the history of one, *mutatis mutandis*, we shall give an outline of the peculiarities of the other. Mr Wood, the talented discoverer of this new mode of operation, performed for cure of hernia on both occasions. As this operation is so complex, yet so easily adapted by skilful manipulation to meet every exigence and to conquer all emergencies, it is well that the office of explaining difficulties as they arise should come from so able an anatomist. The clearness and precision of Mr Wood's comprehension of the anatomy of the parts implicated in hernia, his capability of lucid demonstration both by word and by diagram, and fertility of resource in novel and unexpected difficulties, are beyond all praise. The number of patients at the present time who have been relieved by cure of hernia on Mr Wood's plan, we believe, is somewhere about thirty; the last case to which we shall revert being in number the twenty-fourth which he himself has had under his care, all but two of which have proved successful. One of these had had several previous operations unsuccessfully attempted in different hospitals. The parts were consequently so cut up as to afford a very slender prospect of success. The patient moreover, a sailor, absented himself, without leave, at the end of a week before the parts were sufficiently firm, walked some distance and indulged in debauch. We still are of opinion that this operation demands a familiarity with the minute anatomy of the parts, and a certain decision and boldness of procedure, that few possess, but with which, in an eminent degree, Mr Wood is familiar and singularly endowed. One of the difficulties to be scrupulously regarded is to avoid the epigastric artery. After much familiarity and practice, as well upon the dead as living subject, he urges the necessity of using the index-finger of that hand which corresponds to the side upon which the hernia operated upon is situated. Thus the right index-finger must be used to invaginate the parts of hernia on the right side, and, *vice versâ*, the left finger for the left side. This is to give, if we may so express it, a correct *tactus eruditus* to govern and guide the needle, armed with hempen thread, properly to the neck of the sac. This is greatly facilitated by the circumstance that the artery slips away when touched by the needle, it being glib, and the areolar tissues in which it is imbedded of a synovial character. Mr Wood stated that he had tried many experiments in a careless manner upon dead subjects. In one instance, where vessels were injected, the needle did catch the artery; being hard and firm, it did not slip away. The case of to-day was singularly complex; the patient, a sailor from the Sailors' Home, a very strong hale man about twenty-two years of age. The hernia was both oblique and direct; Mr Wood had never before seen such a case, the internal ring being dilated and open, as well as the external. He prefers a blunt-shouldered needle to a sharp one, the sharpened point being very small. It lays hold better upon the fibres of the fascia, and, from the smallness of the puncture of the fibres, the ligature is less liable to tear out than from a larger incision. The tenotomy-knife used is very fine and sharp at the point and edge for about two-thirds of its length—edge beyond being removed. The case Mr Wood operated upon on the 6th inst. was a fine young man about twenty-five years of age. The hernial sac was unusually large and dilated, although the hernia was recent. Another singularity characterising it was, that the tumour was as broad at its apex as at its base, and a kind of neck in the region of the ring was marked upon it, as though pressure from a slight collar existed. To meet this unusual state of things, Mr Wood adopted quite a novel mode of operation. In this instance, having to contend with such unusual relaxation and largeness of sac, he adopted a strong iron wire ligature coated with silver, instead of his usual strong hempen ligature. The manipulation he effected and practised included an additional ligature across the relaxed openings. He resorted to a demonstration by diagram to explain this intricate and complex procedure. But even this failed to give a lucid statement of the various and difficult anatomical structures through which ha passed his wire ligatures. We need not say how incapable any verbal explanation would be to effect this, and will not attempt the futile task. On the same day Mr Henry Lee performed the same operation upon a strong, healthful young man, about twenty-five years of age, a sailor sent from the Sailors' Home. This young man had been operated upon before by a modified operation. It is certain that this complex and somewhat bold and unique operation is rather avoided by surgeons. It may be that a fatal termination has more than once occurred in consequence.

Examining and Exploring Knee-Joint.

This patient, a female, about twenty years of age, had suffered for some years from scrofulous disease of the right knee-joint. Although the disease was becoming aggravated, and cartilages were apparently gone, there existed a tolerable degree of movement. Abscesses had formed, communicating with joint, and externally by three openings; the lower opening about the base of patella, the second at the superior part of patella, and a third above, at the extremity of femur, between the condyles, rather on the external aspect of thigh. Mr Lee made a longitudinal incision, from the lower to the second sinus, into the joint. He then examined the condition of joint, and found the extremity of the femur necrosed. He extended the section to the uppermost sinus, applied trephine, and brought away a piece of the necrosed bone. He then gouged out detritus, introduced elevator, and brought away a piece of necrosed bone, which he found already separated, and lying in the cancelli of the shaft of femur. This piece of bone was about one-third of an inch by one-eighth in dimensions. He then scraped away some small particles of detritus, and closed wound with ligature, applying water-dressings. Mr Lee thought a useful limb would be attained. The irritation set up by the condition of disease existing at the extremity of femur, and the loose bit of bone imbedded in it, created great disturbance. The removal of these sources of irritation would give quiet; the bones maintaining a tolerably parallel position in relation to each other, and also free from contraction.

Varicose Vein.

Mr Lee operated by acupressure and subcutaneous section. He stated that acupressure, although a new name, had been practised many years at King's College Hospital. It is effected by introducing two needles underneath the saphena vein at two different points; then passing silk over them twisted in the figure of 8 fashion, or lint lapped round, or pressure in any way will obliterate the vein. The needles are passed under the vein by rolling the vein out of its bed, and, on thrusting them through, rolling the vein back again upon the needle. A fine-edged tenotomy-knife is then introduced in the same way, rolling the vein out of the bed, and, on introduction of knife, returning it again over the flat knife. Then turn its edge upwards, and cut through the vein under the skin. The cutting of the vein must be done with some force, the coats of veins being very tough and hard to divide. It is, moreover, an important feature that the inner coat of the vein should be carefully divided. If not divided, you do not obtain adhesive inflammation of its inner serous coat. In that case, if clot forms, it softens and becomes absorbed; and no poison is so fatal to human life. Clot will form no adhesion to the sides of the vein. It will have a shining appearance, as if surrounded by a serous membrane; but, if carefully examined, will be found to have formed no attachment on one side of the vessel. Thus, if the inner coat be not completely divided, the adhesive juice will not be found to have formed union. In the case operated upon, an abscess had formed on the lower part of the leg three months back. It was produced by languid circulation: the enlarged varicose veins having returned the blood so slowly as to become almost stagnant, the nutrition of the parts was conse-

quently defective, and great vascular debility existed. Thus ulceration occurs from innutrition of areolar tissue and teguments. The obliteration of these varicose veins gives vigour, tone, and increased rapidity of circulation to the blood, which before passed slowly and languidly in one or more enlarged veins. The circulation being now conveyed through vessels of smaller calibre, nutrition of cellular tissue is improved, and ulceration becomes cured. Mr Lee said that the ulcer in this case would heal in about three weeks.

NECROSIS OF HEAD OF FEMUR.

The patient a female, about thirty years of age, received injury of right knee about six years since, for which she had treatment at St Bartholomew's and other hospitals, and obtained cure by anchylosis. She continued well for two or three years, when she had a fall, which revived disease in knee-joint. She suffers greatly, the disease being active, and her health is declining. The knee, Mr Bowman said, was no longer a joint; he would treat the femur, and tibia and fibula, as one bone. He had no doubt the condyles and lower extremity of shaft of femur were diseased; also that he should find caries and necrosed bone between the condyles—in the cancelli, and up the shaft for some distance. This was a case in which formerly amputation would have been performed. Mr Bowman made a horizontal section down upon the joint, extending over the condyles of femur; traced sinus down to diseased bone; which having reached, he with strong nippers broke away—which required great force to do—a considerable portion of necrosed bone. He then scooped out detritus and dead bits for some distance up the cancelli and shaft of the femur. He said he had no doubt there remained more carious or necrosed bone yet to come away. These, he said, could be got at and traced at any future period. A useful limb would be preserved by the plan of conservative surgery adopted. The usual dressings were applied.

EXAMINING ELBOW-JOINT, AND FORMING FALSE JOINT.

This was a case of anchylosis, in which the bones were straight, without any flexion of joint. In consequence, the limb was useless, rigid, and always in the way. The object Mr Lee entertained was to disturb and overcome this condition of parts. He made a longitudinal incision over the ulna, and somewhat to the internal aspect of the limb, down to bone, and dissected round it and the shaft of humerus and condyles. He then cut, with circular-acting saw, out through the ulna at its base, and flexed the forearm. By thus maintaining the flexed position, he would obtain ligamentous union and some latitude of motion by what may be called this false joint, and from having been worse than useless the limb would be rendered serviceable. Mr Lee stated that other modes might have been resorted to. Thus, by extension, counter-extension, and manipulation, dislocation or fracture might with great force and violence be done, and a certain quantity of flexion, and perhaps motion, be obtained. But fracture could not be had where most desired, and more mischief might by these violent measures be done than in so delicate a subject as the female operated upon would be justifiable.

Mr Lee likewise operated upon another female patient, about thirty years of age, for the removal of necrosed bone from the lower extremity of left humerus.

MR LAWRENCE AT LYONS. — We extract the following paragraph from the 'Gazette Médicale de Lyon':—"The Profession of Lyons has, within the last fortnight, been afforded great happiness, without, however, being able, from not being prepared, to appreciate it fully. Last Wednesday, whilst M. Desgranges was extirpating a tumour in the parotid region, at the Hôtel Dieu, an aged gentleman entered the theatre, with a fine, intelligent countenance, and an exquisitely noble English bearing. He introduced himself as surgeon to St Bartholomew's Hospital in London, and made a few extremely appropriate remarks respecting the operation which was being performed. He then accepted the invitation to be conducted over the hospital by a few young doctors present. In leaving them, he bade them good-bye in the following manner: 'Many thanks, gentlemen. If you come to St Bartholomew's Hospital, I shall be happy to show you round. Pray ask for Mr Lawrence.'"

MEDICAL SOCIETIES.

MEDICAL SOCIETY OF LONDON.

MONDAY, OCTOBER 8TH, 1860.

A. B. GARROD, M.D., F.R.S., PRESIDENT, IN THE CHAIR.

This was the Opening Meeting of the Session.

The following paper was read by Dr Thudichum:—

ON SOME CHEMICAL QUESTIONS IN CONNECTION WITH DISEASES OF THE LIVER AND THEIR TREATMENT.

We will give, as far as we are able, an abstract of the main features of the discussion upon this paper.

Dr THUDICHUM had on some former occasion entertained a portion of this question, and had communicated a theme to the Fellows of the Medical Society "On Gall Stones." In this paper he inferred that biliary calculi, by the process of deposition by which they were formed, conveyed a model or formed casts of the biliary ducts. This inference he had had corroborated by independent opinions of those to whom he had shown them. Dr Thudichum used a mode of expression or new term, cholochrome, to explain a colouring substance he found precipitated on granules in these casts. Thus he considered a sort of decomposition takes place, resulting in the deposition from healthy bile of these granules, held by the bile in solution in a healthy state. This discovery of cholochrome, so called, and of its constituents and properties, he had explained in papers he had communicated to the British Association and other societies. He had since extended inquiry, and added to his facts sufficient *data* upon which to build a theory of the construction of gall stones. He would explain this, and also the influence of the parenchyma of the liver in its normal and diseased function. He would also submit some therapeutical suggestions for the treatment of diseased liver, derived from these physiological inquiries. He recited several experiments to show the analysis of so-called cholochrome. He also further gave the results and changes bile manifests under putrefaction. Some in different phials were shown, kept two years, and others one year, respectively. The deposits they gave were analysed, explained, and shown. The results gave chlorochrome, cholic acid, phosphates of lime, and magnesia, in crystals and mucus. The fluid portion contained certain salts, taurine, valerianate of ammonia, and phosphate of soda. Dr Thudichum then entered into an inquiry into the organic physiology of the liver, and the functions of the cells. They absorb albumen, starch, and sugary matters, which they convert into bile. In disease, instead of normal assimilation, a fermentation occurs. Then he reverted to treatment of liver disease. The therapeutic means he suggested in jaundice were nitric or nitro-hydrochloric acid, or a solution of nitrous acid taken as a ptisan, like lemonade. It produces no irritation, griping, or disturbance, as does nitric acid and aqua regia. They act as solvents of cholochrome, and as tonics and antiseptics, so much required in diseased conditions of the bile; but they are not specifics. Other remedies to stay the morbid actions are wanted. Astringents, as gallic acid, sesquichloride of iron, and the tincture of sesquichloride of iron, are beneficial, especially the last, in epithelial desquamation of the liver. These acids, he said, were much improved by dilution; the more diluted, the more decided the effect. They are quicker assimilated; they are always well received by the stomach when well diluted, but not unless. Their action is doubtful. They may pass free in the circulation, and act upon certain tissues. This is satisfactorily established in relation to oxalic acid, and others which pass uncombined through the circulation, they having been found free in the urine. There is no explaining these organic chemical changes during life. Dr Thudichum deprecated mercurial treatment in liver disease, in the strongest terms, as a "fatal error." The simple mineral drinks, Seidlitz and purgative salts, were indicated by the condition of the intestinal canal; baths of aqua regia, with simple juicy vegetable acid diet, conducing to a good condition of skin. It was his fate to have to treat for results of blue pill as much as liver disease. Dr Thudichum recommended soluble phosphates; their presence is always beneficial and desirable; their absence may be injurious, since the assimilation of fat without them would be imperfect. It might be taken in the food, like common salt, and in combination with it. They, the two latter, produce an emulsion easily assimilated. He suggested the combination of cod oil with phosphates, to improve the digestibility and agreeableness of the fat. Liebig recommended their being administered in the menstruum of beef-tea. In bile, soda exists more largely than potassa. The substance of the liver shows a reverse proportion of these salts. These relations require further inquiry; their disproportions may explain disease. The modes of speech describing morbid conditions of liver lead to error, having no definite connection with its true conditions. Chologogues are little wanted. The errors of the liver are little understood; it is more often injured than benefited through the mouth. The intestines require most regard. To appease, subdue, and quiet their irritability and activity, are more indicated. We have given but an imperfect report of this very elaborate and intricate paper, erudite in chemical analysis and speculative induction.

The President, Dr GARROD, on the part of himself and the Fellows of the Society, returned the thanks of the meeting to Dr Thudichum for his very erudite paper. He called upon the Fellows to offer any remarks in the way of discussion or inquiry of the experiments so clearly given; to the accuracy of some he himself could speak. He was afraid the subject was too elaborate and speculative to admit of much off-hand discussion, or to come within the scope of any but practised and professional chemists.

Dr RICHARDSON, who had arranged to read a paper this evening before the Fellows of the Society, first explained the cause of his not doing so, and the mistake from which it arose. He then made a few remarks upon Dr Thudicum's paper. He should have wished for more explanation of the treatment, and also of the diagnosis of diseased liver, and of that condition of it which led to the formation of gall stones.

Dr LEARED was also inquisitive to know more of the diagnosis. Dr Leared remembered many cases in which the state of things was such, that immediate relief was obtained by the administration of nitric or nitro-muriatic acid. He inquired, "How is it that Dr Thudichum finds mercury so injurious in liver disease?"

Dr SALTER inquired concerning the decomposition of fibrin? if urea implies the presence of uric acid, and whether you get it in the bile-duct? In answer to Dr Leared, he would say that mercury exercises no effect whatever—has no truly chologogue influence. We are quite in the dark in administering mercury as a chologogue. He put three questions to Dr Thudichum, which our space does not permit giving.

Dr ROUTH suggested that Dr Handfield Jones had proved to the Society that mercury and aloes were both chologogues.

Dr THUDICHUM made a full reply in respect to mercury. It was never detected in the bile, and does not exert any direct influence upon the liver. If it acts at all, or beneficially, it [illegible] getting out of the system as soon as possible through the intestines. Its specific action always does harm. It decomposes the red particles of the blood—deprives it of oxygen. In reply to the direct question, Is mercury a chologogue? he would reply with another, What is a chologogue? Is it an increased secretion of the quantity of bile? If so, is it increased by mercury? He never could find any mercury in bile. Dr Thudichum said—"They who gave mercury, according to my opinion, do harm." But he would work with Dr Richardson in further experiments of a physiological character upon dogs. All fishes' bile contains only potassa, no soda, notwithstanding they live in an element of soda. Man and other animals' bile, on the contrary, contains soda, and no potassa.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, OCTOBER 3, 1860.

DR RIGBY, PRESIDENT, IN THE CHAIR.

Eighty-four new Fellows were elected by ballot in the usual manner.

Dr R. UVEDALE WEST related a

CASE OF SEROUS APOPLEXY TERMINATING FATALLY IN THIRTY-FIVE HOURS ON THE SIXTH DAY OF LYING-IN.

The patient, aged thirty-eight, was delivered

on June 4th, 1860. She was of full habit, with a remarkably dingy, freckly complexion, suggesting the idea of imperfect elimination of urea. Her last confinement, the fifth, took place in June, 1859, when she had violent post-partum hæmorrhage, with subsequent febrile symptoms and phlegmasia dolens. Her state of health since that period had not been good. The labour which preceded her death was easy and quick, but the placenta was incarcerated, and had to be removed. For a day or two there was much hæmorrhage, but she was otherwise pretty well until the fifth day, when, soon after breakfast, without previous complaint, she was suddenly seized with a kind of fit. When seen by Dr West, soon after this attack, she was found semi-comatose and speechless; hemiplegia of right side; the arm on this side rigid and semi-flexed; pupils medium, equal; no convulsive movements, but occasional motion of the left hand and arm; respiration quick; pulse 100; lochia present; breasts distended, the child having died the day before; no œdema of feet or ankles; bowels open day before. When sharply spoken to, she apparently attempted to put out her tongue. She remained in the same state up to the evening of the following day, when, after turbulent tossing of left arm, rising in bed, quickened pulse, copious perspiration, hurried sibilant respiration, she expired.

The head only was allowed to be examined. There were small patches of extravasation inside the scalp over both sides of occiput, due to knocking of the head against the head-board; brain apparently congested on surface; some small patches of softening outside the left choroid plexus. Left lateral ventricle empty; right contained considerable quantity of slightly bloody serum. Brain otherwise healthy.

Dr TANNER regretted the absence of any mention as to the state of the vessels of the brain. He thought it highly probable that this may have been one of those cases of plugging of one of the cerebral arteries by fibrin to which Virchow, Kirkes, and others had called attention. The condition of the woman was such as to favour the formation of such impediments to the cerebral circulation.

Dr GRAILY HEWITT regretted rather that the condition of the kidneys had not been ascertained. The details of the case led him to suspect, that had they been examined, they would have been found diseased, notwithstanding the fact that no œdema was observed at the time of the attack. He was led to make this remark in consequence of his experience of a case somewhat similar to the one now reported, and in which disease of the kidneys gave rise to pretty nearly analogous symptoms and a like result.

Mr HENRY G. TIMES next related a

CASE OF QUADRUPLE BIRTHS.

The great rarity of quadruple births—according to Collins' statistics, 1 only in 129,172 births—induced the author to lay the case before the Society. The patient, aged thirty-three, was pregnant for the fifth time. She was taken in labour on the morning of the 23rd of September. At eight p.m., a female child was delivered by the midwife in attendance; ten minutes after a second child, and twenty minutes afterwards a third, were born. Then followed a very large placenta, when the midwife, finding there was still another child, sent for Mr Times. The placenta had drawn down the abdomen of the remaining child. After a little manipulation the feet were drawn down, and delivery of this, the fourth child, effected. The first three were alive crying; the last never breathed. There was little hæmorrhage. The previous pregnancy terminated at eight months, in December, 1859. The last catamenial period was during the first week in March, but the discharge was so scanty that she conceived herself to be then pregnant. Hence the quadruplets were probably between six and seven months old. The children were all well formed, all upwards of twelve, and one thirteen, inches in length. The first lived seven hours; the next two, three hours. The placenta was single, but each funis had a distinct attachment. There was no lobulation of the placenta. The patient recovered well.

Dr ROUTH inquired whether the movements of the children within the abdomen had given the woman any evidence of the uterus containing so many live occupants?

Mr TIMES stated that the only thing observed by the woman was, that her abdomen was unusually large—a fact she accounted for by supposing that there was a large quantity of liquor amnii present.

Dr BLOXAM stated that in a case which came under his own observation, all four children were born alive, and at the full term.

The PRESIDENT made some interesting observations respecting plural births in general. He believed that, as stated by Hohl, the size of the abdomen was no criterion. Hohl found that in cases of twins, the abdomen was not often larger than in ordinary cases. He knew of a case in which the same woman had quadruplets twice within the year, and he had heard of cases of triplets twice or thrice over. He was himself one of six children, the six being the result of two pregnancies, one of which resulted in the birth of twins, in the other, of quadruplets. In answer to a question of Dr Tanner, as to the greatest number of children he believed had been born at once, he referred the Society to Burdach's Physiology, in which several very remarkable cases would be found quoted. If he (the President) recollected aright, there was one instance, if not more, in which six children had been produced at a birth.

Dr GINN believed that in most of these cases of quadruplets the children die. He had met with a curious instance while travelling in America, however, having had pointed out to him four young ladies, sixteen years of age, who, by common repute, were the product of one pregnancy.

Dr W. TILBURY FOX read a paper

ON THE PATHOLOGICAL LESION OF PHLEGMASIA DOLENS.

The paper was an appendix to a former communication read at the June meeting, in which it was attempted to show the necessary conditions of evolutions of phlegmasia dolens; and the object of the present paper was to solve two main questions:—

1. The essential condition of the limb (the pathological lesion) of phlegmasia dolens.
2. The mode of production of this lesion.

In regard to the first point, it was maintained that the presence of fibrinous serosity in, with more or less hypertrophy of, the fibro-cellular tissue, is the essential, the sufficient, pathological lesion; that the inflammation, the abscess, the sloughing, &c., are not peculiar or necessary parts of the affection, but common to many diseases, and the result of an eliminative act to rid the system of some *blood-poison*; that the latter may produce lymphatic and venous obstruction, and hence phlegmasia dolens; but it passes beyond this, giving rise to a distinct disease—such as abscess, pyæmia, and the like.

Phlegmasia dolens in these cases is a local complication of the general disease, and the general symptoms are not parts of the phlegmasia dolens. It follows, then, that there are two types of the disease:—

a. The complicated, in which an eliminative process (inflammation, abscess, &c.) takes place, these being the answer acts of the tissue to the blood state; the epidemic form, in which an effect is produced by a virus, superadded to what occuss in—

b. The other class,—the uncomplicated,—where the blood state does not require any eliminative actions to be performed on the part of the tissues, but where simple obstruction exists, such as pressure by tumour, &c., and simple thrombus; this being the essential, simple, ample disease,—all else being superadded and accidental.

It having been shown that venous obstruction produced œdema *only*, and this *plus* lymphatic obstruction (phlegmasia dolens), the second question, as to the mode of production of the lesion in the limb, might be stated thus—How can obliteration of the lymphatics produce the peculiar change of the limb in phlegmasia dolens? The lymphatics being obstructed, the three offices, of removing waste, of absorption, and of formative power, could not come into play.

It was then argued at length that the amount of lymphatic distribution and fibro-cellular tissue are in direct ratio—that fibrin is the pabulum of the latter tissue—and that Virchow's views on this point clash with sound doctrine. Lymphatic obstruction being followed by the retention of fibrinous serosity in the cellular tissue, the inference allowed by the foregoing facts was, that *one* office of the lymphatics is to remove all superfluous material from the cellular tissue—to keep the balance of nutrition there correct; hypertrophy and retention of fibrin in the cellular tissue ensuing upon lymphatic obstruction: and this explanation is confirmed by the behaviour of the lymphatics in cases of cancerous ulceration, &c. (When a blood-poison is present, *special tissue actions*—as abscess and the like—are superadded.)

It was attempted to be shown that absorption by the lymphatics from ulcerated surfaces might give rise to thrombus at the entrance of the thoracic duct into the junction of the jugular and subclavian veins, and thus account for phlegmasia dolens occurring in the upper extremity in cases of disease of other parts of the body—e. g., cancer uteri.

RATHDOWNEY DISPENSARY.

Wednesday last, the Committee of the above Dispensary met in the Donaghmore Union, for the purpose of appointing a Medical Officer in the room of the late Dr Harte.

There were, it appeared, three candidates for the situation, but only one—Dr Smith of Mountrath—had complied with the terms of the advertisement, which required personal attendance on the day of election.

Mr Stubber proposed that Dr Smith be appointed Medical Officer for the Rathdowney Dispensary District.

Mr Scott—I have great pleasure in seconding the proposition.

Mr Atkinson directed attention to a resolution passed on the occasion of the appointment of Dr Harte, to the effect that tickets for Medical relief should not be issued to persons rated over 6*l*., except in urgent cases, Dr Harte having agreed to visit such cases for a fee of 5*s*. He (Mr Atkinson) thought Dr Smith should be made acquainted with that resolution, and requested to state whether he would adhere to the same practice.

The Board agreed to call in Dr Smith accordingly.

On hearing the minutes read,

Dr Smith said he was a member of certain Medical Societies, on entering which he had undertaken an obligation not to do anything derogatory to their rules. To visit patients for a fee of 5*s*. would be a breach of those rules, and he therefore considered he was bound to consult them before he agreed to the resolution read to him. He might tell the board, however, that the resolution was perfectly illegal. The Commissioners would never sanction such a compromise between a Dispensary Committee and their Medical Officer.

Mr Scott—They have sanctioned it.

Dr Smith said he could assure them that if the Medical Officer sent up that resolution to the Commissioners they would tell him that it was perfectly useless, and that he need not act on it. He then explained the practice of the Mountrath Committee. If a member of it gave a ticket to a man who was able to pay, he (Dr Smith) wrote back what his means were to his own knowledge, and, if the member was satisfied, the ticket was cancelled; if not, and he said—"Doctor, you are wrong," he attended the patient, and there was no more about it. He never had a word of difference with his committee.

Mr Stubber said the rule of the society Dr Smith had alluded to as prohibiting him from taking 5*s*. was a very bad one and must be injurious to themselves. There were a certain class of farmers who were not able to pay 1*l*. and yet did not like to accept gratuitous Medical relief.

Mr Baird said by the Medical Charities Act a man who accepted gratuitous Medical assistance was disfranchised.

Dr Smith said he would be very glad the society would rescind the rule, for if they did, he would be able to make plenty of money by it.

Mr Stubber referred to advertisements he had seen where Medical men in London gave attendance for a fee of 5*s*.

Mr Southern said it would be worth a person's while when they got sick to go to London, where they would be attended to for a fee of 5*s*. (A laugh).

Dr Smith said they would find it was not so cheap after all, for every time the doctor looked at the patient he (the patient) had to pay down 5*s*.; whereas, when the guinea was paid, several visits were given without additional charge. He had done so often.

Mr Atkinson said the resolution he had read

only applied to Dr Harte, and ceased to be in force at his death.

After further conversation, the committee agreed to proceed with the appointment without regard to the resolution.

The motion for appointing Dr Smith having been put, was passed unanimously.

Dr Smith suitably returned thanks, and the proceedings terminated.

Births, Marriages, and Deaths.

BIRTHS.

LINEKER.—On the 8th inst., at Nottingham, the wife of E. H. Lineker, Esq., M.R.C.S., of a daughter.

MORISON.—On the 9th inst., at Wellfield House, Wingate, Durham, the wife of John Morison, M.D., of a son.

MARRIAGE.

WHITCHURCH—BROMLEY.—On the 4th inst., at Rippingale, Reuben Whitchurch, M.D., of Melton Mowbray, to Sarah, daughter of the late Henry Bromley, Esq., M.R.C.S., of Rippingale.

DEATHS.

BURROW.—On the 8th inst., at Ventnor, Isle of Wight, Wm. Thomas Holme Burrow, Esq., M.R.C.S., of Settle, Yorkshire, aged 34.

CAMPBELL.—Recently, David Campbell, Assistant-Surgeon, R.N.

CARTER.—Recently, William H. Carter, Assistant-Surgeon, R.N.

CONNELL.—Recently, W. Connell, Deputy Inspector-General, Army.

DEMPSY.—On the 5th inst., at Woolwich, aged 55, C. Dempsy, Esq., Inspector-General of Hospitals.

EVANS.—Recently, William Evans (seniority, July 24, 1808), Surgeon, R.N.

HARWOOD.—On the 5th inst., at Holles street, Cavendish square, William Harwood, M.D., of Rugeley, Staffordshire.

HARGOOD.—October 10, Charles Benjamin Hargood, of Highbury place, Islington, late of Battle, Sussex, M.R.C.S. Eng., L.S.A. Lond.

HOWELL.—September 26, at his residence, Wandsworth, Surrey, James Howell, M.R.C.S. Eng. 1812, aged 69.

MAXWELL.—Recently, Robert Maxwell, Surgeon, R.N.

MORRIS.—October 4, at his residence, Wickham villa, New Cross, Harvey Morris, Staff-Surgeon, R.N.

ROUTLEDGE.—September 26, at Berry Edge, Durham, Edward Routledge, sen., formerly of Alston, Cumberland, where he was in practice for fifty years, aged 79.

SMITH.—September 30, at Bridgeland street, Bideford, Devonshire, Thomas McKenzie Smith, M.R.C.S. Eng., L.S.A. Lond., aged 47.

TOWSEY.—Recently, Henry Towsey, Surgeon, R.N.

WOODS.—At Godmanchester, Charles John Woods, Esq., F.R.C.S., aged 53.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of Medicine, and received certificates to practise, on October 4th, 1860:—John Godfrey Bride, Saxmundham, Suffolk; Robert Jennings, Pontypridd, Wales; Richard Henry Milson, London. The following gentlemen also on the same day passed their first examination:—Charles Radcliffe Bond, Catherine place, Greenwich; Edward Olive, Hillingly, Sussex.

APPOINTMENT.—Walter Goodall Copestake, M.R.C.S., L.S.A., was elected House-Surgeon to the Derbyshire General Infirmary, on August 27, 1860, in place of Mr Dolman, resigned.

PRIZE SUBJECTS AT THE COLLEGE OF SURGEONS OF ENGLAND.—The Collegial Triennial Prize of fifty guineas: The Anatomy and Physiology of the Supra-renal Capsules. Two Jacksonian Prizes of twenty guineas for 1860: 1. The Healthy and Morbid Anatomy of the Prostate; 2. Diseases of the Knee-joint requiring Amputation or admitting of Excision, and the relative Advantages of the two Operations. Two Jacksonian Prizes for 1861: 1. The Structure and Diseases of the Lachrymal Passages at the Inner Side of the Orbit; 2. The Best Method of effecting the Radical Cure of Hernia. The Dissertations for the Collegial Prize to be sent in by Christmas-day, 1861, and those for the Jacksonian Prizes on Christmas-day of the respective years.

CAMBRIDGE.—MEDICAL DEGREES.—The examinations for medical degrees in the present term will commence on Monday, Nov. 12th. Candidates will be required to satisfy the examiners in the following subjects:—Hippocrates: the 1st, 2nd, 3rd, and 4th sections of the Aphorisms. Aretæus: the first five chapters of the 2nd book of the 'Causes and Symptoms of Acute Diseases.' Celsus: the 2nd book. Candidates will have to produce their certificates before admission to examination. The lectures connected with the study of Medicine for the ensuing year have been published. The physicians will attend at the hospital on Mondays, Wednesdays, Thursdays, and Fridays, for medical instruction, at ten a.m.; and the surgeons on Tuesdays, Thursdays, and Saturdays, at eleven a.m., for surgical instruction. In order to obtain certificates of attendance on the medical practice of the hospital, and also on the medical clinical lectures, pupils must have attended on the physicians' practice three times at least in each week during term-time, inclusive of the clinical lecture; and for the certificate of attendance on the lectures on Clinical Surgery, attendance on the practice of the surgeons during three days in each week, inclusive of the clinical lecture, will be required. Pupils are recommended to attend both the physicians' and the surgeons' practice concurrently, and the above regulations are made for the purpose of facilitating such attendance. Attendance on the lectures on Botany, Chemistry, Materia Medica, Anatomy, Physiology, and Dissections, is recognised by the Royal College of Surgeons of England as one of the sessional courses required by the regulations of the council of that College. Students entered to the practice of the hospital are admitted to the clinical lectures without additional fee.

PATHOLOGICAL SOCIETY OF LONDON.—The first meeting of the Pathological Society was held at the Rooms, 53 Berners street, on Tuesday evening, the 16th inst., at eight o'clock.

Mr C. F. MAUNDER, formerly Demonstrator of Anatomy at Guy's Hospital, has been appointed Assistant-Surgeon to the London Hospital, after a contested election ending in a majority of 235 votes.

ANOTHER HARMLESS INGURGITATION OF A WHOLE HOMŒOPATHIC PHARMACY.—The children of an inhabitant of Erfurth, in Germany, having discovered their father's homœopathic pharmacy, swallowed all the globules of opium, arsenic, belladonna, &c., without the least unpleasant effects.

THE USE OF TOBACCO IN INDIA.—The 'Indian Lancet' of February last states that the native prisoners of the Punjab, Madras, and Bengal were prohibited from smoking by the authorities, and that three months after the order had been carried out no evil consequences had arisen from this sudden deprivation.

QUININE SENT TO ITALY.—We understand that Lady Panmure, who has taken a lively interest in the welfare of the sick and wounded consequent upon the war in Italy, has this week given orders to a firm in London immediately to forward to Messina and Naples a large quantity of quinine, for the use of the patients in the hospitals of those cities.

STATISTICS are at present the rage in Paris. An enthusiastic proficient in that study lately calculated that fifteen milliards of men have perished in the various wars which have been waged since the creation of the world. Carrying his calculation still further, he estimates the blood shed in these wars at 3,560,000 barrels; and taking the weight of each man at an average of 100lb., he concludes that 1,560,000,000lb. of human flesh have been cut to pieces by hostile weapons.

CHURCH LANE A CHURCHYARD.—In the fifth Report of Sanitary Progress of the National Philanthropic Association, it is stated that of 100 children born in Church lane, 31 die before the first year; in the whole of St Giles's, 28; Lambeth, 20; City of London, 19; Islington, 16. Out of 100 children living at one year and under two, there die in Church lane 46; St Giles's, 15; Lambeth, 10; City of London, 12; Islington, 7. The report adds that it will be seen that, while only 7 in 100 die in Islington from one to two years, 46 die in Church lane, which should be called Church yard rather Church lane.

MR SANDS COX.—The report of a commission appointed by the Société de Chirurgie of Paris to examine a treatise by Mr Sands Cox, 'On Amputation of the Thigh at the Hip-joint' (with a successful case), and which was published by that gentleman in 1845, has just been issued. It enters fully into the merit of Mr Cox's publication, and bears ample testimony to his professional ability and research. The recommendation with which the commission close their report, that Mr Cox be elected a corresponding member of the Society, was unanimously adopted. The report was read to the Society by Baron Larrey, surgeon to the Emperor, and son of the famous Baron Larrey.—'Birmingham Gazette.'

THE LAST SUMMER IN RUSSIA.—The summer has been very warm at St Petersburg, the heat having been greater than during the hot summers of 1832 and 1858. This presents a rather striking contrast with the severe weather which has prevailed in Central Europe.

A SANITARIUM AT THE CAPE.—A number of skilful artisans and mechanics have been selected from the companies of Royal Engineers at headquarters, Chatham, with orders to embark at Southampton, on the 5th inst., for the Cape of Good Hope, to assist in the erection of the sanitarium which the Government has decided on establishing at that station for the sick and wounded troops from India and China. The sanitarium is intended to be formed of huts, and will be erected near the locality of Winsberg, about eight miles from Cape Town. Dr J. R. Taylor, C.B., who has been appointed chief medical officer, has been for some time at the Cape superintending the erection of the various buildings, and organizing the medical staff of officers for the new establishment. We are glad to find that the principle of segregation of the sick in huts, as opposed to that of massing them in huge hospitals, is to be adopted. Medical science has long demonstrated the superiority of this system.

HEALTH OF SCOTLAND.—In the eight principal towns of Scotland, containing in 1851 a population of 784,306, and now estimated to have a population of 908,146, the births in the month of August were 2561, the deaths 1738, the marriages 556. It is satisfactory to see that the excessive mortality of 1860 is at length arrested, and the deaths reduced to the average or a little below it. The daily deaths in the eight towns were 96 in February, and above 80 in March and April, but have been falling in number ever since, and were only 56 in August. This, however, is a higher mortality than that of London. The population of these eight towns in 1851 was almost exactly a third of that of the metropolis: the deaths in the eight towns in August were at the rate of 392 a week; but the deaths in London in August, instead of being three times that number (1176) in a week, scarcely exceeded 1000. But the mortality of London last August was nearly 200 a week below the average of the last 10 years (corrected for increase of population), and there might have been an improvement in the mortality returns of the Scotch towns but for the prevalence of epidemics—measles in Glasgow, small-pox and measles in Dundee, and scarlet fever in Leith, Paisley, and Aberdeen. The mean temperature of the month was in Aberdeen 51·8 deg., in Edinburgh 57·8 deg., in London (Camden-town) 58 deg. The depth of rain at Greenock was 5·60 inches, at Glasgow 4·47, at Edinburgh only 1·65; at Camden-town it was 4·48. Of the births in the eight Scotch towns 9·6 per cent. were illegitimate, and Aberdeen retains its pre-eminence; in that city 18·1 per cent.—more than one in six of the children born—were illegitimate. In the detailed returns for all Scotland for the second quarter of this year instances such as these occur:—Hawick, out of 97 births, 13 illegitimate; Inverury, 10 out of 36; Auchindoir, 5 out of 19. One local registrar lays the blame on "field labour;" another, on the girls going into service in "the low country;" a third attributes a decrease of the immorality to "abundance of employment and high wages promoting marriage;" a fourth, who says his return tells a fearful tale, slily adds that, having five active clergymen to less than 1500 people, "it cannot be charged against a want of the means of grace."

Ulster Medical Protective Association.—The committee of this association met, recently, at the General Hospital, Dr R. Stewart in the chair. After the transaction of the ordinary business, Dr Browne, the Honorary Secretary, brought under the notice of the committee the names of several persons reported as illegally practising medicine, to whom he had sent the approved cautionary notice. From some of these persons he had received satisfactory replies, but in other instances the statements were evasive. After some discussion, it was resolved to bring these cases under the notice of the next quarterly meeting, in November, that such steps might be taken regarding unqualified practitioners as likely to put a stop to their illegal and dangerous proceedings. The Secretary likewise read letters from Dr Quinan, the Secretary of the Irish Medical Association, and from Dr Mackesy, of Waterford, relative to the commission which is likely to be appointed to inquire into the working of the Irish Poor-law. The meeting expressed the ardent desire of the Ulster Protective Association to co-operate with the other medical societies in procuring for the country and for the Profession a better administration of the law than there is at present; and the secretary was directed to convey to Drs Quinan and Mackesy the views of the committee on this very important subject. The Chairman then directed attention to a case reported in the local papers lately, relative to a "medical man" having been brought before the magistrates and fined for a trespass, &c., on the County Down Railway. On investigation, however, by the Ulster Protective Association, it was found that the individual in question is not connected with the Medical Profession, as his name does not appear either on the Medical Register or on any authorised professional list. The committee thanked Dr Stewart for noticing the case, as they felt the Profession had no right to have the person referred to ranked among them.

The Indian Medical Service.—We extract the following important article from the 'Madras Daily News and Spectator' of July 13th:—"We understand that the few candidates presenting themselves to compete for Medical appointments in the Indian Army, has roused the Secretary of State for India to inquire of the Local Governments, or Governors, why this branch of her Majesty's service has become so unpopular with the public, that only eleven competitors presented themselves to fill forty-three vacancies lately announced to exist in the Bengal, Madras, and Bombay Presidencies. It is whispered, too, in well-informed circles, that an able and talented Medical Officer at the Presidency has been requested to report upon the very important subject—'Why young Medical men decline to enter the Indian service?' A lucid report will, doubtless, be furnished by the learned officer consulted; nevertheless, we question if any Medical Officer or Officers at the Presidency, however able he or they may be, can fairly and honestly represent the grievances under which the junior members of the Indian Medical Service abour. And we would impress upon the authorities the danger of relying upon the report or representation of any single officer on the Presidency Staff, as he cannot possibly furnish a reliable statement. Few of those either have any grievances to complain of, they having been bountifully provided for the day they landed in India, and continue up to this day to receive the benefit of the State, though their varied talents are equal to any emergency, from the high office of Educational Inspector to the menial one of superintending the cleansing of a sewer, if a salary be only attached to the responsibility. If his Honour in Council really desires to ascertain the grievances of the service, and to furnish a trustworthy report, we recommend him not to call upon the junior Medical Staff at the Presidency, hardly one of whom has ever been beyond Presidency limit. Let the hard-working Military Surgeon be consulted, and the young and old Assistant-Surgeons who have been knocked about for years on active service and general duty on a miserable pittance. These are the officers who understand, and can faithfully represent, the grievances of the service, and feeling of its members; and it is the echo of their grievances in the halls and colleges of the United Kingdom to which the stoppage of the supply of Medical men is to be attributed. Is a wretched pittance of 225 rupees at a half-batta station, and 255 rupees at a full-batta station, minus subscriptions to the Medical and Military Funds, sufficient to maintain a gentleman and family, almost certain to be separated from him in the local service, by a system of sending officers on general duty, although not in the home service? Added to this, the exigencies of the service necessitate a young man to be kept constantly on the move, and to bear his own travelling charges. Who can peruse these facts without perceiving a grievance? Is it not a grievance to be compelled by your covenant to contribute to a bankrupt institution (the Medical Retiring Fund) an amount equivalent, after seventeen years' service, to purchasing an annuity of 300*l.* per annum, and only receive 100*l.*—perhaps not even that amount? Or if an unfortunate officer should by ill-health be compelled to retire one day before he has completed the regulated service, no money is refunded; the amount subscribed is lost to the poor man and his family. Government, although compelling officers to join these institutions, exercise no sort of surveillance over their management; hence the Medical Fund has become bankrupt, and her Majesty's Warrant having bestowed merely empty rank, the service has justly become unpopular."

A Dreary Prospect.—The 'Revue Contemporaine' publishes a very curious article, by Baron Ernouf, entitled "De l'Appauvrissement du Sol et des Moyens d'y Remédier." Is it true that, owing to the gradual increase of population, the surface of the earth is destined, in the course of ages, to refuse its aliment to the human race, and that a day will come when the sun shall shine on an unpeopled and desert globe? Such is the question asked by the author of the article—a question started by many eminent men since the commencement of the present century. It is a positive fact that, in consequence of the populous state of many countries which, during the middle ages, were but feebly peopled, it has become impossible to leave a large quantity of land alternately fallow for a certain time, until the soil has regained the phosphorus which, under different forms, it has yielded to the grain so necessary to the sustenance of man. It is equally true that the manure spread over the fields is insufficient to renew the supply of phosphorus; and that countries like Mesopotamia, for instance, which in the olden time were remarkable for their fertility, have since been transformed into deserts. Nor can it be denied that in taking food we absorb an enormous quantity of the fertilizing element, phosphorus, in order to build up and repair our osseous system, which is almost exclusively composed of phosphate of lime. Did we, on quitting this sublunary abode, restore to the earth what we received from it, the loss to the community would be comparatively small; but this is what we do not; our dead are enclosed within stone vaults or impenetrable coffins, and thus, out of filial piety or respect for the dead in general, we are induced to withhold from our mother Earth that very nutriment which she is so much in want of to feed us, while we multiply in nearly a geometrical ratio, and go on drawing upon her resources until she must be reduced in the end to a state of hopeless barrenness. And what is then to become of the human race? Will it have to live upon fish, or will anthropophagy be its last resort? To these dismal presentiments, the accomplishment of which we may comfortably view from the convenient distance of many centuries, Baron Ernouf replies by pointing out that from the moment chemists discovered that the great agent of fertilization is phosphorus under various forms, the problem may be considered in a great measure solved, since it is reduced to the simple condition of providing that great agent. Among the chief remedies against any deficiency in the natural supply, there are the importation of guano and the application of mineral phosphates to agricultural purposes; and, before these fail, other sources will undoubtedly be discovered by science. To these reflections of our author we may add that increase of population is invariably regulated by the means of existence, and that, whenever there is any danger of an excess of the former, Nature applies a corrective in the form of some pestilence or other great calamity—even when men themselves do not, following their instincts, either destroy each other in battle, or drain off the surplus by emigration. These, history itself shows, are quite as natural checks (though apparently of a political nature) as those alluded to which are independent of our will.

APPOINTMENTS FOR THE WEEK.

Wednesday, October 17.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.
Hunterian Society.—8 p.m.

Thursday, October 18.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.
London Home.—2 p.m.
Harveian Society.—Introductory Address by the President, 8 p.m.

Friday, October 19.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, October 20.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, October 22.

Operations at the Royal Free Hospital, 2 p.m.; Metropolitan Free Hospital, 2 p.m.
Medical Society of London.—8½ p.m.

Tuesday, October 23.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

Mr W. J.—Cases of purpura are not frequent, and are sometimes preceded by febrile symptoms previous to the appearance of the eruption; behaving thus like an ordinary eruptive disease. Gallic acid and turpentine are useful internal preparations. When hæmorrhage occurs on the skin or gums, it may be controlled by tannin. Hæmorrhage from the gums is, however, sometimes arrested with much difficulty. Steady pressure is very useful.

Chirurgus.—Yes.

M.D.—Not until a new charter has been obtained.

Hemicrania.—1st. No.—2nd. Yes.—3rd. We cannot advise you.

A Poor-Law Surgeon.—The Commissioners have a discretionary power in such a case, and their dictum is law. We consider that the course you propose to take would be very imprudent.

Paterfamilias wants information on the composition and qualities of the various farinaceous foods that are vended. We believe them to be composed mainly of pea and wheat flour, in various proportions. Hard's is said to be simply baked flour; the Arabica Revalenta, to have a proportion of lentils.

Mr Henry E. B.—Received.

M.R.C.S. and L.A.C.—The charges are fair and recoverable.

A Student.—Certainly; it shall be inquired into.

Mr Edwards.—Forwarded.

J. F. M.—Dr Hawkins has stated that his letter has been misunderstood, but in what particular way he does not explain. The Medical Council has not yet passed any specific regulations on the subject of classical learning: *the Student will therefore be subject to the rules now in force at the Examining Boards.* We explained what these were last week, in our Notices to Correspondents. It is understood that the period for commencing Professional study will hereafter date from the period of commencing hospital attendance. More specific information can be obtained from the Registrar. It is quite time that the Council came to a definite decision upon these matters.

T. L. will see his questions fully answered in the reply to J. F. M.

Dr J. H.—1st. No.—2nd. Yes.

Medicus.—Write to Dr Hawkins for any information not contained in the answer to J. F. M.

Dr Gibbon.—Received.

Hot-air Douche or Stream.

To the Editor of the Medical Circular.

Sir,—The effect of this process is marvellous in its action on hard glandular swellings, and in drying up cancerous wounds. The apparatus of metal worm, lamp and bellows, is moderate and portable, and can be worked by the individual's foot. I am, Sir, &c.,

Colin McK. Dick.

1 Saville street, London, W., Oct. 5, 1860.

Letters received with enclosures:—E. T. Meredith, F. Wright.

NOTICE OF REMOVAL.

W. LADD, Manufacturer of Microscopes, Improved Induction Coils, and Philosophical Instruments of every Description, begs to inform the Scientific Public that he has REMOVED to more extensive Premises, situated at

11 and 12 Beak street, Regent street, W.

CLINICAL LECTURES.

ON DISEASES OF WOMEN.

DELIVERED AT ST THOMAS'S HOSPITAL,

By CHARLES WALLER, M.D., Obstetric Physician to the Hospital.

Lecture I.—On Polypus Uteri.

Gentlemen,—In the division of the Course of Clinical Instruction to be delivered at this Hospital, it will fall to my lot to bring before your notice those diseases which are peculiar to females, and which, for the most part, arise from their genital organisation. You all know the meaning of the word Clinical—that clinical teaching literally means bedside teaching; in other words, the lecture given from time to time ought to have reference to some individual case or cases within the wards of the hospital. This plan, of course, will be followed as far as practicable; but a little reflection will convince you that in this respect the Obstetric Physician is not placed on the same vantage-ground as his colleagues, they having under their superintendence a much larger number of patients. Twelve beds only are appropriated for the reception of women suffering from diseases peculiar to their sex—some of these highly important and interesting, and well worthy of your careful observation and diligent attention: nevertheless, I feel convinced I shall have occasionally to refer to my private practice for illustrations of the special diseases which may engage our consideration.

There are no disorders which excite more apprehension, not to say alarm, in the minds of female patients, than those which are peculiar to their sex.

The genital organs exercise a wonderful influence on the mind of the female. Slight deviations from their natural functions, in themselves probably of trifling import, fill them with alarm and dread; the constitution sympathises, and a host of symptoms arise, depending upon general nervous disturbance. How cheering, under these circumstances, to be enabled to calm all this mental agitation (and you frequently can do so), by a confident assurance that, notwithstanding their sufferings, the malady is free from danger! On the other hand, it must be remembered that cases of a highly dangerous character often occur, where the symptoms are at first so slight as either to be overlooked entirely on the part of the patient, or at any rate considered too unimportant to require the assistance of a medical man; so that, when his opinion is for the first time required, the case may admit of nothing beyond mere palliative measures. A great mistake has been committed of late years by very many who forget, or probably do not believe, that local disturbance and pain have very often a constitutional origin, and who consequently direct their entire attention to that which may be only a symptom, whilst the disease itself is overlooked.

I am thoroughly convinced that many of the so-called uterine diseases have been greatly aggravated by the powerful local treatment which has been adopted; that many a poor unfortunate cervix uteri has been leeched, cauterized, and subjected to a variety of applications without benefit, when rest and soothing applications, conjoined with constitutional treatment, would have accomplished a perfect cure.

The uterus is an organ subject to a great variety of diseases. Some of these, through producing a vast amount of distress, are curable; whilst others are of a decidedly malignant character. Again, from the peculiar position of the uterus, and its loose attachment to the surrounding parts, it is capable of being acted upon by mechanical causes, producing various forms of displacement. The organ is suspended by the broad ligaments which connect it with the sides of the pelvis; its situation has been aptly compared with the clapper of a bell, a considerable degree of swinging motion being allowed. Where there is a relaxed condition of these ligaments, which constitute its natural support, the organ descends into the lower part of the pelvis, and sometimes protrudes to a greater or less extent through the external parts (procidentia). The formation of a tumour commencing in or descending into the pelvic cavity must, of necessity, push the uterus out of its natural position, either forwards, backwards, or sideways, according to the locality of the swelling. Again, if the fundus uteri be enlarged to a certain extent, either from disease or pregnancy, powerful action of the abdominal muscles, such as violent straining efforts at stool, will sometimes force the fundus uteri downwards, and backwards into the hollow of the sacrum (retroversio). The same effect is supposed to have been produced by a highly over-distended state of bladder. This cause acts, however, in an opposite direction to the former; for whilst the fundus uteri is pushed downwards and backwards by abdominal muscular contraction, the cervix uteri is pulled upwards and forwards by the ascending bladder, the mal-position of the uterus being the same in both cases. It is doubtful, however, whether the distension of bladder so constantly occurring in cases of retroverted womb be not the *effect* rather than the *cause* of the displacement.

I purpose to direct your attention, this morning, to a form of uterine disease often accompanied with alarming symptoms, yet benign in its nature and curable in its character. I allude to that form of tumour designated polypus of the womb, of which we have had several examples lately in that portion of Ann's Ward appropriated to female diseases. In the present lecture I shall not advert to what is termed malignant polypus, which is one of the many forms assumed by that terrible disease, carcinoma. Now, what is a polypus? As ordinarily occurring, it may be defined to be a tumour growing from the internal surface of the uterus, attached by a peduncle, usually attended with frequent and severe hæmorrhage. This definition must be received with some exceptions: in some rare cases, there is no hæmorrhage of any considerable amount; and again, the stalk-like attachment of the tumour may be external to the uterine cavity, being attached to the labium oris uteri. This, however, is not common. (*a*) In the case of Susan Reynolds, recently admitted into Ann's Ward, there was, as I shall presently mention, no hæmorrhage to lead to a suspicion of the existence of a polypoid disease. There are, however, exceptional cases. The point of attachment is usually within the cavity of the womb, and the growth progressive from above downwards. The early symptoms of a polyp are, in the first place, a more than ordinary flow at the menstrual periods, with intervening leucorrhœal discharge; soon the bleeding becomes greater and its repetition more frequent, and at length the hæmorrhage becomes alarming in degree and almost persistent, although more copious at one time than another. Slight bearing-down is sometimes complained of; this is not, however, an invariable symptom, except when the tumour has acquired a considerable size. The amount of hæmorrhage by no means corresponds with the magnitude of the polypoid growth; it may be large when the growth is small, and *vice versâ*. Where the patient has an irritable stomach, dyspepsia with nausea or vomiting is frequently present. If the substance be very large, some local inconvenience, the result of pressure, will be experienced: the bladder or the rectum, or both, may suffer from this cause; or there may be pressure on the larger pelvic veins, producing a varicose condition of the lower limbs. By and bye, the strength fails, the patient exhibits a bloodless appearance, and there is loss of appetite and emaciation of body. Hysterical symptoms, with signs of general nervous agitation, now manifest themselves; and probably, at this late period, the patient consults the medical attendant for the first time.

Diagnosis of Uterine Polypus.—The existence of polypus can only be ascertained by a digital examination, all the symptoms described to you being present in many other morbid conditions of the sexual organs.

Where the growth is small and entirely within the cavity of the uterus, it is beyond the reach of the finger; but in cases where it has passed through the opening of the os uteri into the vagina, there is no difficulty in the diagnosis. A firm tumour is felt in the vagina: on passing the finger upwards, it is usually felt to be pyriform in shape; where the os uteri is within reach, it will be found that the pedicle at its upper part passes through it, the surrounding margin of the os completely encircling it, as represented in this painting. This peculiar attachment allows much mobility in the growth; so that if the finger be pressed forcibly against any part of the polyp, or if grasped by the hand, it can be made to move freely in all directions. A peculiarly diagnostic sign of this uterine growth is, that it possesses no sensibility: if it be scratched with the nail of the examiner, no pain is experienced.

I now show you another painting, in which the polypus is represented as growing from the internal surface of the cervix uteri. In this case you will, on examination, be able to pass the finger through the os uteri anteriorly *only*, its passage posteriorly being resisted by the thick stem. Be careful not to confound this with fibrous tumour embedded in the substance of the cervix.

Where it is of large size, and fills up the cavity of the vagina, some little difficulty is experienced in ascertaining whether it be a peduncular growth, or whether it be a fibrous tumour imbedded in the *labium oris uteri*, projecting downwards into the vagina: in this case the usual pyriform shape is absent, the upper part of the tumour is broad, and no peduncle can be felt. Polypus uteri has been mistaken for inversion, and even for prolapsus; the history of the case will assist in the diagnosis from inversion, which can only occur soon after parturition, unless the fundus be dragged down by the descent of a large polypus or other growth. This is very different from the common inversion. The central opening in a prolapsed uterus, and the sensibility of the substance, will enable you at once to detect prolapsus uteri. I show you, however, a preparation where, from the shape of the tumour, and from a central depression at its lower part answering to the situation of the os uteri, the nature of the case was mistaken, and the affection supposed to be prolapsus.

Let me now direct your attention to the two cases at present in Ann's Ward.

Case 1.—S. Reynolds, about twenty-five, married, but has no child. Catamenia regular as to time, but somewhat more profuse than ordinary—not, however, to any great extent. Has been for some time rather unwell, but could not call herself ill. About three weeks ago, while standing in the upright position, had a sudden fright: at that moment a large substance, "the size of two fists," protruded from the vagina; this was attended with alarming collapse, requiring the use of stimulants. A large quantity of blood was suddenly lost; and this was the first attack of serious hæmorrhage, which was not renewed. Two medical men were sent for, who considered it a case of inversio uteri, and, after very considerable effort, succeeded in pushing it into the vagina, where it remained. This happened at some distance from London. On the 3rd October she was sent up from the country, and placed under my care in Ann's Ward. On examination, a large tumour was felt blocking up the vagina, smooth and somewhat yielding to the touch, pyriform in shape, void of sensibility, and moveable. Its size prevented the finger reaching the os uteri until the whole hand was introduced: the narrow pedicle was then felt, and the nature of the case sufficiently clear. The patient was kept quiet for a few days; the ligature was applied on the 8th, and came away on the 12th; after which the tumour, from its size, had to be removed by the hand. The uterus, on examination, was found healthy, and the patient is now tolerably well.

Case 2.—Elizabeth Bullin, ætat. thirty-six, married; has had two children, the last two years old.

(*a*) An oil painting, representing a polypus growing from this situation, was here shown.

She has a pale, bloodless, unhealthy appearance; has lately lost flesh, and has become exceedingly attenuated; the bowels are tolerably regular; has but little appetite. Thus far the general symptoms, now for the local. For the last twelve months there has been hæmorrhage in a greater or less degree, at first occurring chiefly at the menstrual periods; latterly the discharge has been profuse and frequent, occurring on every slight bodily exertion, the quantity so large as to produce faintness; a bearing-down sensation has been experienced of late, with some difficulty in micturition. Examination detected the existence of a large, hard substance in the vagina, very moveable, and insensible. Carrying the finger upwards, the os uteri was distinctly felt *anteriorly*, but not posteriorly, the tumour appearing to be closely attached to the cervix uteri; no distinct pedicle could be felt. I have several times ligatured a large polypus where I could not trace the circumference of the os uteri through its entire extent, and as I can feel a decided diminution of size in the tumour anteriorly, I shall not hesitate to adopt my usual plan of treatment. I shall in another lecture describe to you a variety of cases of polypus uteri, and now beg your attention to the mode in which the ligature is applied.

This was practically illustrated in the ward by applying the ligature in the case No. 2.

The ligature used by Dr Waller was composed of silver wire twisted round a thread of strong silk, which, he stated, was far preferable to whipcord; the instrument, Gooch's double canula, furnished with Ashwell's rack, with a slight alteration in the construction of the barrel around which the ligature is wound.

ON LARYNGEAL PHTHISIS.

Delivered at La Charité,

By M. PIORRY.

There are already before the public some excellent works on the subject of phthisis laryngea, at the head of which I would place the remarkable work of M. Trousseau, which contains important documents relating to this matter. In laryngeal phthisis, you sometimes find ulcerations of the laryngeal membrane that are supposed to be of tubercular origin; at other times you have caries of the cartilages; or, again, you may have syphilitic ulcerations. From these results destruction of the vocal chords, by which are produced certain inevitable morbid phenomena, to which we shall presently recur.

The work to which I have just alluded, remarkable as it is, is at fault in supposing that this kind of phthisis may be a simple affection. Some hundred cases have now come under my notice; and if certain syphilitic cases are passed by, I have always found pulmonary phthisis in combination with the cases just mentioned. If some hold a contrary opinion, it is owing to their faulty percussion, or their inability to account for morbid unity. This I have ascertained, not only at the hospital, but in private practice, and have found it in ninety-nine cases in a hundred of those who suffer from laryngeal phthisis.

The larynx, as you know, is an organ extremely complex,—composed of many cartilages that play one upon another, that are united by ligaments, have muscles to give them motion; are furnished with a mucous membrane, vessels, and nerves, and with vocal chords formed by the thyro-arytenoid muscles. There is, besides, the epiglottis, which prevents fluids passing into the larynx; as well as muscles that lie externally. The arteries are from the superior thyroideal, and branches also run from the inferior thyroideal to the larynx. The absorbents go to the sub-hyoideal glands; and the nerves are from the superior and inferior laryngeal. Should the mucous membrane of the larynx become inflamed, and there should be between the bodies in contact incessant action, the case is not one of laryngeal phthisis, though it may be one of laryngæmia, or of laryngitis; or, should false membranes be formed, one of plastic laryngitis.

Many of the symptoms of laryngeal phthisis may be present where this affection does not in reality exist; and many organopathic states have been classed under this name. There are chronic inflammations of the larynx, with all the symptoms of laryngeal phthisis in its last stage, when fluids pass into the larynx. There exist in such cases ulcerated pulmonary tubercles, when nothing more can be done than treating the case as you treat phthisis pulmonalis. In such instances, the chronic laryngitis is nothing but the result of the coexisting phthisis. There is another variety, in which the local symptoms are not at first accompanied with symptoms of laryngeal phthisis: these are the cases where you have syphilitic excrescences. The patients find respiration difficult, and difficulty of speaking and aphony arise. If the disease have its seat in the guttural opening, fluids find their way into the larynx; but there is an entire absence of pulmonary symptoms—no absorption of pus, no hectic symptoms, no physical signs on the part of the chest. Besides, you can carry the finger to the superior orifice of the larynx. You have the laryngoscope also at hand: outward palpation, the antecedents of the patient, ulceration of the penis, syphiodermesis, exostosis, falling off of the hair, &c., all concur in this case to throw light on the diagnosis. The treatment is the same as that had recourse to in the affections styled venereal; and the prognosis is the same. These syphilitic affections are always serious, and may go on to ulceration of the cartilages. The best treatment is to give 0·03 centigrammes of protoiodide of mercury night and morning, and 0·50 centigrammes of iodide of potassium night and morning, but at different hours. For the local treatment, cauterisations are employed, and mercurial fumigations; the former with azotate of silver. Ammonia has been used for cauterising the larynx; but it has not answered at all with me, and may occasion untoward symptoms. I remember an armourer who was phthisical; he had laryngeal phthisis, and I applied azotate of silver to the larynx, some of which slipped down, and the patient was nearly suffocated. For three months he has been well, so far as the larynx is concerned. Tincture of iodine also may be applied with a similar view. Some mercurial preparations may be useful, as well as certain surgical means. All this, however, is not laryngeal phthisis, but simply ulcerations of the larynx. Do these exist as primary affections? I think not, if exception be made of cancerous ulceration. When you explore the larynx by means of palpation externally, you discover more or less tumefaction; for I do not know in the records of science where a case of ulceration occurs without swelling.

Other kinds of Ulceration: Tubercular Ulceration.—I have seen one very curious case of ulceration occupying the back of the pharynx and larynx, over the cricoid cartilage, the breadth of the little finger, of a greyish colour, and very painful. It occurred in a phthisical patient who had become as meagre as a skeleton; and the cricoid cartilage pressing constantly on this surface, ulceration of the trachea was the result. He died ere many days. In a great number of phthisical patients these ulcerations of the larynx occur, and constitute the laryngeal phthisis of authors. They may occupy all the points of the mucous membrane, and are sometimes seen affecting exclusively the vocal chords, when the hoarseness may become excessive; or they may extend to the epiglottis, and destroy not only the mucous membrane of the larynx, but also a great portion of the cartilages. Pus is formed, and the sufferings are frightful.

Treatment. — When the disease is but a simple lesion of the mucous membrane, the larynx must be allowed to repose; the patient should inhale the steam sent up by warm water, and avoid breathing cold air, or air impregnated with hurtful particles; and he should also use emollient and astringent gargles.

When the mucous membrane is tumefied, and looks as if œdematous, silence must be enjoined, and the inhalation of aqueous vapour continued. In laryngitis, almost every physician recommends speaking in a low voice; but scarcely can anything be more hurtful, for in speaking in this manner great efforts are made, which fatigue the patient excessively. Such patients should, when speaking, utter only very short words. When you wish to speak loud, you take a deep inspiration; and when the larynx is thrown into action, air is required; and this organ performs its office more easily when there is abundance of air than when the quantity is small. I would, in reference to this, recommend you to follow the practice of the Italians rather than that of the French, for they begin low and finish with a loud voice. If you cannot make your patient speak after taking a deep inspiration, his larynx must be in a bad state. Some time ago a man from Rouen came to me, and said, in a voice that I could scarcely hear, "Monsieur, I cannot speak: our physicians tell me that I am suffering from laryngeal phthisis." I examined, but outwardly found nothing,—nothing on the part of the cartilages of the larynx. The patient speaks low, but without pain, and the sounds emitted seem to be pharyngeal rather than laryngeal. "I have suffered for a month from my throat," said he, "and I have been enjoined to speak only in a low voice." I immediately desired him to take a deep inspiration, and to speak in a loud voice,—which was no sooner said than done, and so loud that I thought I should in consequence lose my own hearing.

When articulation is excessively difficult, you must forbid speaking. When ulcerations are supposed not to exist, and there is neither tumefaction nor hyperæmia, use astringents—a thing not to be easily done. They may be employed in the form of vapour. Alcohol may also be used, and so may tincture of iodine. Never employ ammonia, for in such cases it is a detestable remedy. Tar-vapour has been proposed; and you may use also the vapour of water, though it does not always succeed. Would smoking stramonium be advisable? This substance gives immediate relief, but causes narcotism. The chief remedial means are derived from respirable vapours. Nitrate of silver in solution may also be applied to the larynx, but it has the inconvenience of producing a degree of suffocation. This mode of treatment we owe to the school of Tours. Would I employ caustics? No; never! A good way is to use gargles containing astringents—sulphate of zinc, for example; but they must be allowed to descend sufficiently in the throat.

Let us suppose a case of primary laryngitis; though that is rare. Should there be ulceration, employ the same treatment. But where is the ulceration situated? You must know that. In this case the physiological diagnosis comes to our assistance. When your patient cannot speak, or speaks excessively low, you may tell that the inferior vocal chords are implicated; for, were it the superior, the modifications of the sounds uttered would not be considerable. Were I certain of the existence of ulcerations in the larynx, I would propose the following operation:—Considering that in the mesial line there are scarcely either vessels or nerves, and there being no fear of danger from hæmorrhage, I would cut down, in the mesial line, from the upper to the lower edge of the thyroid cartilage, so as not to endanger the vocal chords. I would next separate the lips of the incised cartilage, so as

to be able to inspect the interior, and ascertain the lesions affecting the vocal chords. Light would not only be thus thrown on the disease, but caustic might be applied. This, however, is but one point of view. The idea may be good, or it may be without any good result. Cauterising is then to be employed, in the application of which we are assisted by the laryngoscope. Where there are lesions of the cartilages, in addition to cauterising, local measures must not be neglected. In cases of this kind, I prescribe iodide of potassium, with the mercurial treatment—0·03 of proto-iodide of mercury night and morning. You may also employ the liquor of Van Swieten. Should there be excrescences, they are to be extracted.

Fortunate are they who see only cases of simple laryngeal phthisis. For my part, I have almost always seen laryngeal phthisis complicated with pneumophymia. These last are to be treated as phthisis pulmonalis.

THE SPIRIT OF THE PERIODICALS.

The 'Lancet' opens this week with a continuation of Dr Brown Sequard's Lectures *On Paralysis of the Lower Extremities*. We extract it :

"There is no affection of the spinal cord or its membranes that presents such varied symptoms as tumours. According to the seat of the tumour, there are symptoms of disease of the heart, the lungs, the walls of the chest or of the abdomen, lumbago, neuralgia, &c. The irritation of the anterior or the posterior roots of one or several pairs of the spinal nerves is the cause of these symptoms, and their variety depends upon the degree of irritation, and also upon the nerve that is irritated. In the beginning of the affection, besides some symptom owing to that cause, there is pain at the part of the spine where the tumour is situated. Usually this pain is increased by pressure on the spine. When the disease progresses, myelitis, and sometimes meningitis, are produced. If it be myelitis, which is a very frequent occurrence, there are sensations of formication or of pricking, as if with pins and needles, in the paralysed limbs; spasmodic movements or simple twitchings, or a great rigidity, appear in those limbs ; the urine becomes alkaline, and sloughs or bullæ are formed on the sacrum or the nates. The feeling of a cord tied round the body or round the paralysed limbs is perceived. The pain in the spine notably increases.

"If a meningitis is produced by the irritation of a tumour in the vertebral canal, there is a rapid increase of the paralysis ; any movement of the spine or of the lower limbs causes a very acute pain ; the muscles of the back become rigid spasmodically, especially when the spine or the lower limbs are moved.

"If no inflammation of the spinal cord or its membranes is produced by a tumour, the symptoms are very similar to those of a non-inflammatory softening, with this difference, that there is pain in the spine, and also the effects of the irritation of the pair or pairs of nerves, originating where the tumour lies in the vertebral canal. When the tumour has destroyed a part of the spinal cord, there are symptoms that vary according to the part so injured. If it be a lateral half of that organ, there is loss of voluntary movement in the corresponding limb, with conservation of sensibility, while in the other limb there are loss of sensibility and conservation of voluntary movement.

"I have lately seen a case of this kind, as far as I can judge from the symptoms. Several periostic (syphilitic) tumours appeared one after the other on the head and face of a gentleman, who, on their disappearance, was attacked with paraplegia, apparently caused by a similar tumour pressing upon the right side of the spinal cord, and producing paralysis in the lower limb of that side and anæsthesia in the left lower limb.

"If the grey matter of the cord be the original seat of a tumour, there are at first numbness and diminution of the power of the will over the bladder, with weakness of the lower limbs. Afterwards, paralysis becomes evident in these limbs, and anæstbesia, in a much more marked degree than usual in diseases of the spinal cord, is observed, together with a loss of the power of directing movements.

"If the posterior columns of the spinal cord are alone pressed upon by a tumour, there is at first hyperæsthesia, with but a slight diminution of the voluntary movements in the lower limbs ; afterwards, when the pressure reaches the grey matter, diminution of sensibility and of the power of the will over the bladder, and increase of the paralysis of the lower limbs. A very interesting symptom—*i. e.*, the loss of the power of guiding the movements of the lower limbs—may be observed in cases of a tumour pressing upon the lower extremity of the spinal cord on its posterior surface. There may be in such cases no real paralysis, or at least all the movements of the various parts of the lower limbs are possible *so long as the patient can see them;* but when he tries to move these limbs in the dark, or when he does not look at them, he cannot succeed in making the movement he wishes to perform. Besides, he does not know where his feet or legs are, unless he looks at them or touches them with his hands. He may be able to stand on his feet when he sees them ; but if he ceases to look at them, he is at once in danger of falling down. This condition depends upon the alteration of some of the posterior roots of nerves, and of the posterior white and grey parts of the spinal cord, producing partial anæsthesia of the skin and muscles of the feet and legs. I have now a case of this kind under my care.

"In cases of tumour in or upon the spinal cord, epileptiform convulsions have often been observed. Sometimes, also, real epileptic fits, with loss of consciousness, biting of the tongue, foaming at the mouth, &c., are produced in such cases. This is what has been erroneously called *spinal epilepsy*.

"I need not say that the nature of a tumour will sometimes serve for the detection of its existence. A cancer, by the general symptoms it causes, will give some additional ground to the supposition that there is a tumour in the spinal canal. If the patient is consumptive, and if the paraplegia has been slow in its development, there is some probability that the tumour supposed to exist in the spinal cord is a tubercle.

"*Diagnosis of a Paraplegia due to a Tumour of the Spinal Cord.*—The only affections which might be mistaken for this kind of paraplegia are meningitis and myelitis. A very limited meningitis localised in the upper part of the dorsal region or in the cervical region might give rise to pretty nearly all the symptoms of a tumour of the spinal cord: local pain (spontaneous and after pressure); sensations of heat or cold, or pricking, &c., in the peripheric part of the nerves, originating where the meningitis or the tumour exists; spasmodic twitchings in the muscles animated by these nerves, &c. In a case of meningitis so localised there is paralysis of the lower limbs, on account of the effusion which presses upon the spinal cord in its lower extremity; and the same cause that produces a paralysis diminishes the reflex power of the dorso-lumbar part of the spinal cord. On the contrary, the whole of the cord below the seat of a tumour, remaining healthy and being separated from the brain, acquires a very energetic reflex power, and the least excitation produces reflex spasms or convulsions in the lower limbs.

"Between cases of tumour upon the lumbar part of the spinal cord, and cases of meningitis limited to the lumbar part of the meninges, the diagnosis is extremely difficult. However, there are more spasms in the muscles of the limbs in the case of a tumour, and more in the muscles of the back in the case of meningitis. Besides, in this last case, the affection would often begin by acute symptoms,—fever, &c. ; and the paralysis would soon extend to other muscles than those of the lower limbs.

"We have described in Lecture II. the various symptoms of myelitis localised in the upper part of the dorsal region, or higher up. It is not very difficult to distinguish this affection from the paraplegia due to a tumour, so long as no degree of inflammation has been produced in the spinal cord by the irritation of the tumour. Amongst the characteristic symptoms which would not be observed in the lower limbs, if there is a tumour and no inflammation of the spinal marrow, are all the referred sensations of pricking, formication, cold and heat, &c. But if a local myelitis is produced by a tumour in the upper part of the dorsal region, or higher up, leaving all the lower part of the cord healthy, the symptoms will be the same as those of a localised myelitis without a tumour. It is only by the mode of beginning of these two affections that it would be possible to distinguish one from the other. In the case of myelitis without a tumour, various sensations and cramps in the lower limbs would have existed from the very commencement; while in the case of a tumour preceding myelitis there would be none of these symptoms in the lower limbs.

"*Prognosis of Paraplegia due to a Tumour of the Spinal Cord.*—We need not speak of the gravity of paraplegia caused by a cancer or a tubercle. The chances of cure, or even of a notable amelioration, when other kinds of tumours, except one, press upon the spinal cord, are almost null. But it is well to know that the duration of life may be prolonged many years, and the degree of paralysis may remain very long unchanged. Tumours owing their origin to syphilis form an exception to the above rule. A cure is possible, and generally a notable amelioration will be observed after the proper treatment is continued long enough. However, even in cases of this kind, if the injury to the spinal cord is considerable, the cure of course cannot be complete, and the amelioration cannot be very great.

"*Treatment of Paraplegia due to a Tumour of the Spinal Cord.*—The rules to be followed may be reduced to three :

"1st. The congestion and the tendency to inflammation ought to be treated by the same means that should be employed in cases of myelitis. In a patient now under my care, who has all the symptoms of a cancerous tumour in the middle of the dorsal region, and who is completely paraplegic as regards voluntary movement, sensibility, and power over the bladder and rectum, I have succeeded in diminishing the pain in the back and the referred pain in the lower limbs, and also the spasms of the paralysed muscles, by the application of a large belladonna plaster on the back, and by the internal use of ergot of rye and belladonna. If there are symptoms of meningitis, together with those directly due to a tumour, the patient must take iodide of potassium, besides the other remedies just named. The spasmodic rigidity of the lower limbs, or the wasting of the muscles, in the rare cases where there is no cramp, no convulsions, and no spasmodic rigidity, requires the application of shampooing or galvanism to the muscles of the lower limbs. Dry-cupping on the painful spot of the spine, or other modes of revulsion, may be found useful to diminish the pains and spasms, and also to prevent a rapid progress of the disease. Strychnine should be avoided, as it would certainly increase both the pains and the spasms.

"2ndly. If there is a probability that the tumour is of a syphilitic nature, iodide of potassium, in larger doses than if there were a simple meningitis, should be the principal remedy ; five grains three times a day is the dose I have employed, with marked benefit, in two cases of this kind. This remedy ought to be taken for at least six months. Against the pain in such a case I employ aconite rather than belladonna, both externally and internally (from five to ten minims of the tincture a day internally). But I make use of ergot of rye as much as in other cases of tumour. If there is the appearance that the tumour is a tubercle, cod-liver oil is to be given. It cannot prove injurious, even if the paraplegia is not due to a tubercle, and it may diminish the pain.

"3rdly. The patient ought to have the most nourishing diet, and a little wine. He ought to take exercise in the open air, and drive if he cannot walk. In bed he should lie on one side of the body, and not on the back. His appetite and digestion ought to be carefully watched, and kept right by tonics, aperients, &c."

Mr Hilton continues his Lectures on *Pain and Rest* in the same journal, and Mr Hancock his on *Division of the Ciliary Muscle*. He reports a series of cases in which this operation was had recourse to in the treatment of Glaucoma, and benefit conferred.

Mr Walter Jessop contributes the following article *On a New Method for the Reduction of Strangulated Hernia:*

"In May last I was called to a case of strangulated hernia (left oblique inguinal), in a man aged fifty-two years. The accident had occurred some thirty-six hours previously. The taxis, opium, chloroform, hot baths—in short, all the ordinary modes of treatment, had been perseveringly applied without success.

"At the time of my visit I found my patient in a partial state of collapse, in a profuse cold perspiration, with great tension of the abdomen, and symptoms of hiccough and nausea coming on. He complained bitterly on my lightly attempting an examination; indeed, the part seemed so exquisitely painful as at once to negative all hope of success from further direct efforts at reduction. An immediate operation was proposed, but firmly declined by the patient and his friends. Desiring them to seek further advice, I left the room, but was immediately recalled, with a request that I would permit of an hour's delay. Agreeing to this, and while waiting in the house, a thought struck me that it might occasionally be possible to relieve a patient under such circumstances without having recourse to the knife. On explaining this to the patient and his friends, they at once consented to a trial of the means proposed.

"Calling a male attendant into the room, I directed my patient, still lying on his back, to the edge of the bed, and, with assistance, separated his legs, placing one over each shoulder of the attendant, who, facing the bed, stooped to receive them; and, in this position, by passing his hands round the fore part of the thighs, was enabled to obtain a sufficient purchase to permit of his raising him on to his head and shoulders on the bed, thus throwing the intestines back upon the diaphragm, and to some extent necessarily making traction behind and directly *from* the seat of strangulation. After two or three minutes' manipulation of the abdominal parietes, I found the tumour become less tense, and drawing forwards the integuments round the point of rupture, I made lateral, upward, and downward movements—jerking, as it were, occasionally the parts immediately contiguous to the stricture. This seemed to excite but little suffering; in fact, the patient, so far from uttering complaint, declared himself, after the first two or three minutes, decidedly relieved—that 'the dead sickening weight that killed his groin,' as he termed it, was better. Continuing these efforts, and varying them as they seemed to occasion distress, I presently felt a slight gurgling under my hand, and almost immediately had the satisfaction of finding the hernia reduced, and my patient comparatively in a state of safety.

"The whole proceeding certainly did not occupy ten minutes. Slight peritoneal tenderness existed for some days, but the man eventually did well.

"The *rationale* of the proposed plan is simple. A mass, large or small, of displaced intestine or omentum must assuredly be more readily withdrawn from its point of incarceration or strangulation by traction from behind than by the best-directed efforts of the taxis. Any one, for illustration, taking the trouble to put a fold or two of his handkerchief in a ring formed by his finger and thumb, and lightly strangulating it, will, on attempting to return it by pushing or kneading from before backwards, find infinitely greater difficulty in effecting his purpose than if he were to make traction from behind. In short, the employment of the taxis is at the best a clumsy and most uncertain mode of proceeding, and I shall venture in future to make it merely supplementary to the plan I now advocate.

"'One swallow fails to make a summer,' and it may be said that the practice of turning the patients *à posteriori* upwards is opposed to all orthodox notions of propriety. Admit all this. Others, with greater opportunities, may happily be enabled to add to my single case; and granting that the position of the patient may be accused of positive inelegance, it may, at any rate, contrast favourably with our proceedings in lithotomy, and in many other operations on the perineal region."

The 'Medical Times and Gazette' contains the ontinuation of M. Claude Bernard's articles on *Experimental Pathology*. The special topic is the *Bile*. We reproduce it:

"The experimental history of the pancreatic secretion having been concluded in our preceding Lecture, an equally interesting fluid now calls for our attention: we allude to the biliary secretion: the intimate connections which exist between the excretory apparatus of the liver and that of the pancreas, the numerous inosculations which unite these ducts, and allow the liquids therein contained to mix freely with each other, and lastly the nature of the functions which they separately perform, render this study an indispensable complement of that which we have just brought to a close: such is the motive which leads us to devote the last Lecture of the present course to this important subject.

"Bile is poured into the intestinal tube by a single orifice, the situation of which is constantly the same: it is placed just below the pyloric aperture of the stomach. In no animal whatever is this fluid poured out upon different points, as in the case of the pancreatic juice; the anatomical disposition remaining the same throughout the scale of being.

"We place under your eyes the stomach and duodenum of a rabbit, and you may judge from this preparation how considerable is the distance which separates in this animal the biliary aperture from that of the pancreatic ducts. Such, however, is not always the case: for the ductus choledocus is in many other species united to the pancreatic apparatus by numerous anastomoses; and in animals deprived of a pancreatic gland (the carp, for example,) Weber supposes that the two organs coalesce into a single apparatus: many other fishes exhibit a similar disposition.

"It is easier by far to obtain bile in large quantities, than any other of the intestinal secretions: the liver being one of those glands which Nature has provided with a reservoir, the most convenient method of obtaining this fluid consists in opening the gall-bladder immediately after death; its chemical and physical properties may thus be readily ascertained: in certain animals, however, the gall-bladder does not exist; the horse is deprived of this organ, while the ox enjoys a prodigiously large one. The reasons of this difference are not known to us: but animals which do not possess this apparatus exhibit considerable laxity of the ducts, which enables the bile to distend them, and accumulate in their cavity. In living animals, the use of anæsthetics would appear convenient; but the liquid thus obtained does not enjoy its normal properties. All secretions, as you are aware, take place under the influence of certain physiological excitations; saliva is poured forth during mastication, and pancreatic juice during the digestive process. The causes which act upon the biliary secretion are hitherto unknown: it takes place during the intervals of digestion: in animals provided with a gall-bladder, the liquid accumulates in this pouch while the animal is fasting, and is poured forth as soon as food arrives into the stomach: in other species it merely distends the biliary ducts. When, therefore, it is intended to collect large quantities of this fluid, the animal must not have been fed for some time previously.

"As soon as digestion commences, the bile flows from its reservoir into the duodenum, but no more is formed within the liver, which begins to exert a different kind of activity, and is occupied in producing grape sugar. In the lower animals it is easy to ascertain this: I have discovered in snails the existence of these two different secretions, which alternately take place: during the digestive process sugar is formed; during abstinence bile is produced, and flows into the stomach; when food is again collected in the stomach, it meets with the bile previously accumulated there, and digestion proceeds, but the secretion of bile is suspended, so that the animal in a fasting state prepares, as it were, a store of its fluid for its next meal.

"The operations performed for the purpose of obtaining this liquid in living subjects were intended in most cases to prevent it from following its natural course; for when its peculiar properties are the object in view, it is found in general more convenient to secure the gall-bladder of animals recently slain. Physiologists, therefore, have endeavoured to stop the passage of bile into the duodenum, in order to ascertain the part which it plays in the digestive process: several authors, in fact, believe it to be an excrementitious substance, having no connection with the assimilation of food. M. Blondlot, in particular, has rendered himself conspicuous among the supporters of this opinion by publishing a series of papers entitled, 'On the Inutility of Bile in Digestion.'

"Haller was led by the anatomical dispositions we have just described to believe that the bile really played an important part in this function: he thinks it impossible that an excrementitious fluid should be poured into the upper portions of the intestinal tube. But similar arguments are of no real value in Physiology, and vivisections must in every case of doubt be had recourse to. Schwann and Blondlot have simultaneously made some interesting experiments upon this subject. Schwann operates upon the gall-bladder itself; but you are aware that the common duct is independent of that which arises from the biliary reservoir: it is anastomosed with the latter in such a manner as to permit the passage of the fluid which it conveys into the gall-bladder, or to allow the bile therein contained to pass at a given moment into the duodenum; but it still continues to pour the biliary secretion into the intestine, as derived from the liver itself, when the reservoir of this gland has been perforated.

"Tiedemann and Gmelin tied the ductus communis just above its outer orifice, in order to oppose the passage of the bile into the duodenum; but a morbid state is the result of this operation: the biliary ducts are distended, the secretion accumulates in the channels which convey it, and the animal becomes jaundiced at first; but after a certain space of time, the rupture of the ductus communis is the consequence of its inordinate distension, and the animal rapidly dies of peritonitis resulting from this accident. In a few cases, however, the ligature falls, the duct is reproduced, and the functions resume their usual course.

"In order to avoid this inconvenience, an opening must be allowed for the secretion to make its escape when its natural course is suspended. M. Blondlot has adopted for this purpose a different proceeding. He ties the ductus choledocus on two separate points; the bile being thus prevented from passing into the duodenum, accumulates in the gall-bladder. An adherence is then established between this point and the abdominal parietes, in the same manner as when hydatid cysts of the liver are opened by Récamier's method (which consists in successive applications of caustic potash to the spot). An opening is then made into the gall-bladder, and rendered permanent by the introduction of a tube. The desiderata of the experiment are in this manner successfully realised; and under such conditions life may be protracted for a very considerable length of time. In this respect, however, the results obtained by various observers do not agree.

"The first effect of the operation is an entire atrophy of the gall-bladder, which is reduced to the proportions of a mere excretory canal, from which the bile flows continually; but shortly after this, an excessive voracity arises in these animals, according to Schwann; they lose flesh, are seized with a profuse diarrhœa, and die sooner or later. In young animals the fatal termination takes place within a shorter space of time than in adults. In a few cases the subjects recovered entirely their previous state of health; but Schwann invariably ascertained that this result was due to the reproduction of the obliterated ducts, and the passage of bile into the duodenum.

"The results of M. Blondlot's experiments are entirely opposed to those I have just mentioned. He states that in a vast number of cases the dogs on which this operation was performed continued to enjoy perfect health, although no reproduction of the ducts had taken place; and he attributes the death of the animals operated upon by Schwann, to their licking the wound, and swallowing the bile which flowed from the opening—a habit rapidly productive of fatal effects. This danger he avoids by muzzling the animal, which prevents it effectually from licking the wound.

"Other observers (and I myself am one of these) have obtained results which agree with Schwann's experiments; but it is certain, at any rate, that death is not an immediate consequence of biliary fistulæ, and only takes place

after a considerable length of time. The operation has been performed upon the dog now placed before you; the wound being now healed (the opening of course remaining fistulous), its health does not appear to have suffered from the experiment.

"The method adopted by Schwann and Blondlot offers one very serious inconvenience: we allude to the definitive interruption of the passage of bile into the intestine, without any possibility of re-establishing the natural order of things. In my own experiments, I have found it more convenient to introduce a canula into the ductus choledocus itself. An adherence having been produced in the usual manner, an incision is made in the duct, and a large tube, open at both ends, and provided also with a lateral aperture, is inserted in the wound. When it is intended to let the bile pass, as usual, into the duodenum, the outer orifice is stopped with a plug, and the bile flows through the lateral aperture into the intestinal tube; when, on the contrary, it is required to arrest its progress, a smaller tube is introduced into the first, which it fills so exactly as to close the lateral opening: the bile then flows entirely out of the body, and not a single drop of this fluid reaches the digestive apparatus. This method offers, however, a serious inconvenience: the tube frequently escapes from the duct, when the animal happens to be restless and agitated after the operation. We have therefore adopted the following system: the tube is plunged into the gall-bladder itself, the ductus communis having been previously tied; an opening is then made into the duodenum; a canula is placed in it, and the two fistulous apertures are allowed to communicate by means of an india-rubber tube.

"These experiments, on the whole, cannot enable us to decide whether bile really is an excretion or a secretion: the effects are not of sufficient importance to enable us to form a judgment on this point, as in the case of other glands. But one of the principal differences between secretions and excretions is the formation of peculiar substances in the liquid which the gland produces, which did not previously exist in the blood: this property of creating new chemical compounds exclusively belongs to the organs of secretion. Now, in this respect, bile evidently belongs to the class of secretions; the numerous substances which it contains do not exist within the torrent of circulation.

"The influence exerted by the nervous system on the biliary secretion is hitherto little known; but the appearance of jaundice after violent moral emotions seems to afford an incontrovertible proof of the power exerted by the nerves upon the liver, as well as upon other glands.

"The plan of this course, gentlemen, does not comprehend the complete study of the physiological properties of the digestive fluids. Our purpose has been to show you the various operativa proceedings which enable the physiologist to collect them. We have now brought to a close the history of these various substances, as far as the experimental part of our studies is concerned; for the secretion of the intestinal glandulæ cannot easily be obtained, and gives rise to few operations on the living subject. In the approaching Session we shall continue this course, and perform, as usual, all our experiments before you; and the digestive apparatus having now been thoroughly studied, we shall devote our attention to the principal properties of the Spinal Cord."

Dr Goodfellow concludes his Lectures on *Bright's Disease*. He explains in this part the grounds of his difference of opinion from that enunciated by Mr Bowman as to the process of the urinary secretion. Mr Bowman's theory may be stated as follows: that the aqueous portion of the urine is filtered through the Malpighian tufts, whilst the organic and inorganic constituents are secreted by the surrounding capilliaries. Dr Goodfellow says:

"Now in examining closely this theory, we must conclude that the blood in passing through the Malpighian capillaries, where the circulation is most retarded, and where the greatest lateral pressure must necessarily be exerted upon their walls, only parts with the water, while the network of capillaries which receives the blood from the small efferent vessels, where the lateral pressure must be very much less, permits the transudation through their walls of ordinary blood plasma, together with the 'organic constituents,' and the 'inorganic salts' of the 'secretion,' in order that the 'true secreting elements' should separate the latter. In order to accept this as true, the capillaries into which the afferent vessel breaks up (the Malpighian capillaries) must have much thicker walls than the capillaries which surround the tubes, and which are formed by the efferent vessels. This difference (if there be any) I have certainly never been able to discover.

"But is it probable that a contrivance so admirably adapted as the Malpighian tuft is for delaying the blood currents, should have for its sole office that of a filter, and that it should separate in part merely the menstruum which holds the more important substances in solution? I do not undervalue this function, even if it be the only function of this elaborate arrangement. There is no doubt that the mere separation of water, or rather that a contrivance suitable for the separation of large quantities of water, under certain states, is indispensable to the economy. It is essentially necessary, in order that the blood may, within certain ranges, be preserved at a uniform density, even under circumstances calculated suddenly to increase the amount of water in it from ingestion or other causes.

"Next, to supply the blood plasma for so much solid, highly animalised, and saline matters as pass off by the kidneys daily, there must be some arrangement eminently calculated to retard circulation, and to favour transudation. What do we find in the anatomical arrangement as described by Mr Bowman? A small vessel suddenly breaking up into a rounded bunch of capillaries, having 'a far greater aggregate capacity than itself, and from which there is but one narrow exit,' the efferent vessel, which also breaks up into a network of capillaries, which surrounds the convoluted channels or tubules. It is impossible to conceive a more admirable contrivance for retarding the blood current, and the efferent vessel being so small, and the capillaries into which it breaks being of smaller diameter than those of the Malpighian bodies, 'it follows, from the law of hydraulics, that there must be a greater pressure against the walls of the latter.' And yet, according to current notions, the capillaries of the small efferent vessel, with this small amount of pressure, are the only vessels from which the transudation of the *liquor sanguinis* takes place, not only for the nutrition and repair of the tissues, but also for the separation daily of upwards of one thousand grains of solid constituents of the urine. Moreover, is it probable that the same blood plasma should at the same time, and in the same part, be the fluid containing the urinary excrements for elimination, and the nutrient matters for nutrition? Two processes, then, quite incompatible with each other, and opposite in their action, are going on with the same fluid, in the same parts of the kidney, and at the same moment.

"Again, the water descending the convoluted tubules or channels, and in contact with and bathing the free surface of the epithelial cells, is calculated to produce an osmotic current in those cells, the very opposite of that necessary for secretion. The current must necessarily be continuous from the free surface towards the attached surface, and therefore towards the blood plasma in the tissues, instead of in the opposite direction. If secretion, therefore, is due in any way to the laws of osmosis, it must be brought to a standstill. So, also, if there be a considerable escape of blood plasma from the Malpighian capillaries, the density and chemical composition of that within the tubes and that in the tissues being the same, endosmotic action must cease.

"But to this it may be said, and very properly, that the nervous force (supposing it to act as the galvanic current is known to do) may make the endosmotic action go on with considerable activity, even under these circumstances. Believing, as I do, in the influence of the nervous force, I am quite willing to give the weight which belongs to this hypothetical answer to my objection.

"But the next objection which occurs to me is a much more serious one. Professor Graham and C. Schmidt have proved that urea possesses great diffusive power in water. It is equal to that of common salt. In solutions containing 20 parts in 100 of water, the quantity of the saline solution diffused was 58·68; that of urea was the same; while the solution of albumen was only 3·08.

"You are aware that it has been discovered by Professor Graham, that the law of diffusion of gases is also applicable to different neutral salts and other substances dissolved in water. That law is—'that the tendency to diffusion diminishes with the increase of density, being inversely proportional to the square root of the density.' It has also been made evident by Schmidt, that generally, when different substances are added to water, the volume of the two combined is smaller than that of the two separately;—that, in fact, a certain amount of condensation takes place. Now there seems to be a law also of condensation. It is—that in proportion to the diffusive tendency of any substance, so is the co-efficient of its condensation.

"Now, urea is a remarkable exception to this; for while its diffusive power is 58·68, its co-efficient of condensation is only 0·160, and that of common salt is 1·505. Its co-efficient of condensation, as found by Schmidt, is the lowest of any other substance that has been submitted to experiment.

"It is highly improbable, therefore,—it is almost impossible—that (to say the least) two substances having such diffusibility through water, should be separated from it by mere filtration, especially such a substance as urea, that admits of no, or but little, condensation with any fluid with which it is mixed. The tendency of such a substance would always be to escape through the pervious walls of a vessel. This I regard as the most serious objection to Mr Bowman's theory, although I think that the others also are entitled to considerable weight. Now, albumen is the very opposite to urea in respect to diffusibility and condensation. Its diffusibility is remarkably low, being only 3·08 in a solution containing 20 parts to 100 of water, while that of urea is 58·68; and its co-efficient of condensation is 0·420, while that of urea, as I have before said, is only 0·160. Albumen, then, from this condition alone, and independently of other agencies, has a strong tendency to remain within the vessels, and but little tendency to pass through their coats with the water, urea, and salts.

"My own idea is (and I mention it with great diffidence, for my subject is not physiology), that, under the combined influence of pressure, quality of blood, and the nervous force, the urinary constituents are separated directly from the Malpighian capillaries, and that whatever constituents of the serum or of the blood that are normally transuded through their walls, are *absorbed* by the epithelial cells of the tubules or by some other agents before the convoluted tubes become continuous with the straight or simply excreting ducts; and that the blood, purged and depurated, which leaves by the efferent vessel, while passing through the network of capillaries in the tissues of the kidney, parts with the normal plasma for the usual nutrient processes, as in other organs.

"It is the common practice to speak of these tubules or channels as mere excretory conduits. This leads to very erroneous notions of their true office. It is probable that the separation of the urinary constituents from those of the serum that may be transuded with them, actually takes place in these tubules, and that it occupies some length of time before the urinary constituents, transuded from the Malpighian capillaries, find their way into the straight ducts. These channels are of extreme length, and highly convoluted. I am disposed to regard them more like the blind tubules of the stomach and other mucous membranes, than as excretory passages, with this difference, that instead of terminating in blind extremities, they communicate with the straight, purely excretory tubes by an open orifice. Not only is a separation of the constituents of the urine probably effected in them, but those matters which are required for the system, and which cannot be lost without detriment, are re-absorbed, just in the same manner that the constituents of the gastric juice after they have performed their office are re-absorbed in the lower portions of the intestinal canal for future use; for none of these constituents are normally found in the fæces."

Dr Goodfellow shows that there is an analogy

for this manner of secretion in the gastric juice. He observes:

"In those secretions which we have been enabled to *see*, the process resembles the one which I have suggested. Take the case of the gastric secretion. According to Dr Beaumont's, M. Cl. Bernard's, and others' descriptions, from actual sight of the secreting process by means of fistulæ, when there is no food in the stomach, and the animal has been fasting some hours, no trace of acidity or indication of the presence of gastric juice can be detected. The mucous membrane is pale and exsanguine, and covered with a layer of greyish mucus, which presents an alkaline reaction. Even when the gastric juice is present during digestion, no trace of acidity can be discovered in the gastric glands, or even below the surface. But, at the moment when the food descends into the stomach, movements are observed to take place, the superficial capillaries become turgid, and the mucous membrane assumes a bright pink colour, and there oozes out from all parts a kind of acid sweat, which raises the thin layer of greyish mucus, and the highly vascular mucous membrane is seen below. Such, in substance, is the description given by all observers of the actual secretion of gastric juice. Previous to digestion there is no trace of any constituent of this fluid on the surface, in the mucous crypts, in the tubercles, in the epithelial cells, or in the underlying tissues. But, at the moment the digestive process commences, the juice exudes from all parts of the surface, apparently from the close network of large capillary vessels—with such rapidity, that, within the hour after food has been taken, the quantity may amount to from two pounds (Lehmann) to seven or eight pounds (Bidder and Schmidt). If all this is 'secreted' through the agency of the epitholial cells, they are more potential bodies than even the most firm believer in cell-powerfulness could have conceived. It is much more probable that the secretion comes at once from the vessels under the agency of a nervous current, or some polar force, excited in a reflex manner by the presence of the meal,—something in the same way that the galvanic current acts in producing rapid osmotic currents through animal membranes, apparently in opposition to the laws of endosmose. The character of the secretion is more probably due to the form of network and the size of the capillaries, as influencing the current of the blood, the anatomical and even chemical composition of their walls, and the peculiar character of the nervous currents, than to the protective and perhaps slowly-absorbing cells that lie upon the mucous surface. It is much more probable that the nervous current has far more influence than the epithelial cells in determining the decompositions and recompositions which make the secretions. If we could by any possibility discover the properties of the currents of all the nerves distributed to the several secreting organs, we might find that each has its own special character and property. The same description might apply to the salivary, the biliary, the pancreatic secretion, and even the secretion of milk, which, I grant, is one that offers some appearance of its taking place through the agency of epithelium. The only reason for this is the presence of milky fluid in the cells, and it is reasonable to believe that this fluid is quite as liable to be imbibed by their free as by their attached surface."

Mr MEADE contributes to the same journal four cases of *Inflammation and Abscess of the Prostate Gland*. We extract two of the cases:

"*Case* 3.—In May, 1855, Mr B., a gentleman about 35 years of age, of delicate constitution, who had been under my care several weeks for an attack of gonorrhœa, from which he had almost recovered, was seized, without any apparent cause, with symptoms of inflammation of the prostate gland. He first complained of pain and irritation at the neck of the bladder; but after a couple of days he referred his sufferings chiefly to the rectum; and on examination considerable enlargement and tenderness of the prostate could be felt by the finger in the bowel.

"Complete rest, warm hip-baths, leeches both to the perineum and round the anus, were tried, but without producing much benefit; and shivering and other symptoms of suppuration made their appearance. The patient continued to refer most of his uneasy sensations to the rectum, and there was little or no impediment to the passage of the urine, though a frequent inclination to make water. I could feel no hardness nor deep-seated fluctuation in the perineum; but one part of the prostate appearing boggy to the touch when the finger was introduced into the bowel, I determined to make an incision into it at once from the rectum, and thus try to prevent the matter from insinuating itself into the tissues of the perineum, or in other directions. For this purpose I introduced a tubular speculum into the rectum, with a good-sized lateral aperture, which I placed opposite to the middle of the prostate gland. The mucous membrane could be seen projecting into the tube, and distinct fluctuation could now be felt by the point of the finger. I therefore made an incision with the sharpened edge of a gum-lancet that had a rounded blade, and after cutting to some depth, about half-an-ounce of thick pus escaped into the speculum. Considerable hæmorrhage followed, but it was soon stopped by retaining the speculum (which had a closed extremity) in the bowel, and plugging it with lint. After thus opening the abscess all the symptoms rapidly subsided, and the patient was soon well. There never seemed to be any discharge of urine from the wound.

"*Case* 4.—In September, 1859, I was called in to see a gentleman, 34 years of age, who had just returned home ill from Scotland. He had recently been married, and had been seized during his wedding trip, while in the Highlands of Scotland, with severe pain in the rectum, accompanied with some obstruction of the bowels and difficulty in making water. He obtained slight relief from taking some castor-oil, and made his way as soon as possible to Glasgow, where he consulted a surgeon, who ordered some leeches to the anus, warm baths, opiate suppositories, &c., and recommended him to travel home as quickly as possible. I found him suffering from a dull pain in the rectum, increased by the sitting posture, from difficulty (but not pain) in emptying the bladder, and also from considerable sympathetic fever. On introducing my finger into the bowel, I found a good deal of enlargement, and great tenderness of the prostate gland. He told me that previous to his marriage he had laboured for some time under stricture of the urethra, from which, however, he had quite recovered; so I have no doubt that there had been sub-acute inflammatory enlargement of the prostate, such as is so frequently consequent upon long-standing stricture, and this had become aggravated by the excitement of the urinary organs consequent upon marriage, together with neglect of the bowels. I prescribed perfect rest in the recumbent posture, warm hip-baths frequently repeated, salines, with hyoscyamus, &c. These measures relieved the pain and general symptoms, but after two days considerable hardness and tenderness appeared on one side of the anus, and the inside of the rectum was very sensitive to the pressure of the finger, a little below the situation of the prostate, showing that the inflammation had spread from the gland to the cellular tissue surrounding the intestine. The prostate itself had somewhat subsided in size, and I could detect no feeling of fluctuation. I now began to fear that matter had formed, and was insinuating itself in various directions; but on the following day my patient told me that during the night something had burst into the bowel, which had given him great relief, and on feeling an inclination to have an evacuation, he had parted with a small quantity of transparent sticky fluid, something like white of egg, but of a yellow colour, some of which he saved to show me. With the finger I could now feel a depression and small opening in the mucous membrane of the bowel in the same situation (rather below the prostate) where I found a tender spot the day before. Small quantities of a similar fluid continued to escape for a day or two, and at the same time all the symptoms, both local and general, disappeared. The enlargement of the prostate also greatly subsided.

"On looking over these cases, do they suggest any points of special interest to which I would call the reader's attention? In the first place, I may remark that surgical authors generally seem to have had a great dread of the formation of either a natural or artificial communication between the urethra and rectum. In cases of abscess in the prostate, deep incision is recommended in the perineum, to prevent the matter from finding its way either into the urethra or rectum. I am anxious to show that this fear as regards the latter canal is in a great measure chimerical, and that it is often even advantageous to make a free opening into the prostate from the bowel, in case of suppuration in that organ, should fluctuation be perceptible, as the matter will be so much nearer the surface in that situation than in any other. The diffusion of matter into the surrounding tissues is thus likely to be prevented.

"The idea of treating chronic suppuration in the substance of the prostate gland by puncture from the rectum is due to Mr W. Colles, but he restricted the operation to a particular class of cases. In the 'Dublin Journal' for 1845 he says:—'There is a description of enlarged prostate in which surgery can render essential benefit to the sufferer, and that by a very simple operation. When we find a patient in advanced life complaining of unusual frequency of micturition, with more than ordinary straining, his urine depositing a good deal of muco-purulent sediment, and possibly a muco-purulent discharge from the urethra, we should make a very careful examination of the state of the prostate. If, under these circumstances, we introduce the finger into the rectum, and find the gland enlarged in either lobe, and, upon pressing on one particular spot, we feel the point of the finger sink, as if into a cavity; and particularly if we find this pressure causes the discharge, per urethram, of a quantity of this purulent fluid, to the amount varying from a few drops to a teaspoonful; here we may hope to render an essential service. The operation to which I allude is simply that of striking a lancet into this hollow soft spot, which will generally be found to contain some matter.'"

Mr CHAPPLE reports a case of *Hepatitis*, ending in abscess of the liver, bursting into the cavity of the abdomen, inducing peritonitis and death. Dr JOHN ALLEN contributes to the same journal a case of *Puerperal Convulsions in a Primapara*, in which peritonitis ensued. The patient recovered. And Dr FIGG concludes his papers on *Turning in all Cases of Labour*. We quote some of his remarks:

"In cases of version without chloroform, I met one instance where flooding occurred; with chloroform, some seven or eight. In no case, however, in a primipara. In that class of patients there is a tone in the uterus ensuring its contraction in defiance of the relaxing influence exercised by chloroform over ordinary muscular tissue. In the event of the uterus of a multipara being nearly imperceptible under the hand applied abdominally a few minutes after delivery, and ere the narcotic influence has passed away, I deem it advisable to rouse her by pinching, when, almost cotemporaneously with the deep inspiration of the waking moment, a manifest contraction of the uterus takes place. I then give an infusion of ergot, previously prepared, in preference to spirits. Whether the former acts in its emmenagogue principle, or, as frequently happens in anæsthesia, emetically, we realise the further contraction of the uterus, in the latter case by reflex action. My experience leads me to a conviction that alcohol suspends uterine contraction, though I confess that it is an excitant of the pulse. Thus the vessels from which the blood flows still continuing open, the evil is increased with the increased rapidity of the circulation. In throwing the uterus into contraction we not only occlude the torn vessels by closing the womb, but we effect the object of the stimulant, re-enforcing the circulation of the system with the surplus blood of the uterus, thrown back into the general current. Let me state, however, that in the darkest cases that I have witnessed, I considered the danger as more apparent than real. If the pulse was below the average tone of vigorous life, it was perfectly adequate to the maintenance of a passive vitality in a horizontal position; and if the expenditure of blood was occurring at the placental site, I knew that it was in accordance with the character of the pulse; that it was slowly flowing out and not violently driven out by high cardiac action. Should such a case present again,—not

having seen one for a long time,—I would no more anticipate a fatal issue than I would if a girl were nauseated under the abstraction of a few ounces of venous blood in my own consulting-room. I may candidly state that uterine hæmorrhage may be possibly produced under another combination of influences in delivery by version. Though, as all physiologists know, the impartation of alimentary principles and the process of fœtal depuration in the placenta take place, not by direct communication with the maternal circulation, but by endosmose and exosmose, I may remind the reader that the membranous cell-walls of the maternal system are not continuous with the lining membrane of the uterus itself, so as to expand over the surface from which the placenta is removed; but, on the contrary, that the terminal cells of the parent project into the parenchyma of the placenta, so that on the *post-partum* contraction of the uterus they are severed, while the placenta is detached.

"If the uterus contract equably beneath the placental mass, it is rapidly peeled off, while the same act of contraction constricts the arterial cells. But if any accident separate a segment of the placenta, the torn cells immediately beneath would close under contraction of the locality; but a terrific effusion might occur in the angle formed by the uterus and reflected portion of the placenta, gushing from the semi-divided cells across that diameter where the reflection ceased and the attachment commenced. In the event of a short or entangled cord, a portion of the placenta may be separated, exposing us to the evil detailed, which, however, has one extenuation. If easily produced, it is easily remediable: remove the whole mass and it ceases. It cannot be denied that, independently of uterine depletion, there is a circulatory depression in a majority of patients in versional delivery under chloroform, which, though transitory and not seriously important, may, under certain measures, be anticipated, or when manifest at once counteracted. If the conclusions drawn from several scores of anæsthetic deliveries can afford reasonable data, I would say that we should calculate the probability of the event, not in the pallid aspect or diminutive physique of the patient, not in the debilitative and sedentary system of existence to which she may have been habituated, but in an approximation to the blonde model of feminine organisation. A complexion where the pure rose alternates with the fair skin—where with light hair we have blue eyes, and a symmetrical rotundity of limb; the very perfection of whose development renders her less able to cope with the slightest shock to which necessity may subject her;—with such a patient I content myself with producing sleep, without the deep stertorous inspiration realised in women of coarser form and dark skin.

"A novice might suppose from the auspicious way in which I have spoken of version in head presentations, that artificial delivery in breech cases could be effected without the shadow of an obstacle. Up to a certain stage, however, they are the least manageable, and worst adapted for manual interference. If the nates present with the legs and feet continuously extended towards the shoulders, the case progresses with greater rapidity than when, as in the majority of instances, the tibiæ femora and trunk form three lines nearly parallel, because the conical form is more apparent in the former.

"When the head presents, the cranial power of resistance refracts, and, in one sense, reduplicates the expressive force of the uterus; but the soft nates yield under the peripheral agency of expulsion, their own dimensions being increased by congestion in greater ratio than the diameter of the os dilatation. From the fact of an infant's limbs being last developed, they are proportionately shorter than the trunk; hence, the nates being lower in position, are in advance of the feet in entering the pelvis. Any attempt to repress the nates, in the hope that the feet might be left on the lower level, would prove delusive, as the uterine parics in close contact with the flexed femora would carry up the feet by the same effort that raised the nates; but if the attempt at delivery were varied by a seizure of the feet, and an exercise of traction to carry them into the vagina, the project must ultimately be abandoned, from the impossibility of causing the femora to revolve the eighth part of a circle over the weakest portion of the uterus, of which circle the child's acetabula are the centres, and the knees the radial distance. Even when, by natural progression, the nates enter the pelvis, manual assistance is long precluded, from the circumstance of one pelvic femoral articulation being alone accessible, the nates obeying the law of the head, entering the pelvis laterally, and always retaining what in nautical phraseology is termed a 'windward' and a 'leeward' side.

"When, however, a stage is attained where the hands can be hooked into the pelvic femoral articulations, the extractive force is brought to bear equally on the fœtus, so as to insure its exit without the risk of femoral fracture, which, I am sorry to say, has occurred to me in impotent attempts to deliver by acting on one side alone. If my memory of Professor Simpson's Lectures fail me not, he recognises only two presentations of the breech. With all respect for the opinion of a man who, in obstetrics, constitutes the soul and centre of my professional faith, I think I have identified four, analogous to Naegele's four cranial; the infant's nates in the third and fourth making the ordinary sacro-iliac turn on the floor of the pelvis. In the practice of version in general labour I have met with four cases of twin births. In three both heads presented; in the fourth, the nates of the leading infant and the head of the second. In the cases where both heads presented, I found that the convex surfaces of the infants were in apposition with the concavity of the uterus—in other words, that the presentations were in each instance first and third, or perhaps second and fourth. My notes afford me no intelligence as to whether the pubic or sacro-iliac presentation was in advance in these cases, nor do I imagine, in the reduced size of each child in twin births, that it would signify. I did not experience difficulty with them, the heads not occupying the same grade,—that of the upper being opposite the umbilicus of the lower. I ruptured the membranes of the leading one and delivered, acting similarly in the second.

"In my early attempts at secret version, I resolved to exercise traction only on the occurrence of a pain, suppressing the effort when the contraction ceased. Though I still observe the pauses formerly mentioned, I deem it perilous to wait for pains that in all probability will not take place for hours after the rupture of the membranes and the alteration of fœtal position. In one instance, having brought the feet into the vagina while the head and neck remained flexed on the longitude of the body, I waited for nine hours for a repetition of contractions, and then, despairing of uterine co-operation, delivered. Having in another case advanced the infant to a similar point, I waited two hours and a half, and then delivered. Both infants and the former mother escaped with impunity; the latter was long an invalid." . . .

"In reference to the children, some cry instantly. The majority do not cry till about sixty seconds have elapsed. Some require bathing and persevering effort to resuscitate. In the delivery of children of this class, however, many Practitioners would have used long forceps, and in all probability extracted lifeless infants. One in fifty of the children may have moaned for an hour; in two I have seen a slight convulsive movement of the feet. In ninety per cent. of presentations of the third, the foot by which the extraction was conducted was slightly discoloured at the malleolus; in three days it spontaneously disappeared. I have only lost one infant during the past year. To form a statistical estimate of the preponderance of advantage or evil in the measure, it is necessary that I give a numerical account of the cases,—how many constituted the aggregate; how many might be distinctively designated impeded; how many natural. On the leading query I may state that I have a memorandum of 317 cases, extending over a period of twelve years. This, however, falls within the number, as I occasionally assisted students in difficult labours, not registering the instances in which it was then adopted. Respecting the second we know,—notwithstanding the admirable rules laid down by authors to guide us to a definite judgment as to what is and what is not an obstructed labour,—that every man assumes an arbitrary prerogative in the formation of his own idea on the subject. We also know from the annals of the Profession, that wherever there is an inclination for any particular measure, there is also a propensity to interpret the features of a case to justify its adoption. I am not prepared to exculpate myself from the charge of having acted under this influence. On the revival of the operation by Dr Simpson, I rigidly collated and compared the various evidences of abnormal difficulty in the instances in which I had recourse to it. Encouraged by success, the following year I relaxed the minuteness of my diagnosis, and included a wider circle. This in turn became too limited for the operation; and thus I progressed until forced to confess that I had crossed the line of demarcation between morbid and natural cases. This transgression of professional rule does not necessarily imply transgression of reason's law. I have only to couch the argument in logical form to ensure a verdict in its favour. That remedy which is equal to the major difficulty is greater than the minor. If version be adequate to safety of mother and child where abnormal complications darken the prognosis, imparting difficulty to the execution, will not the prospective advantage to the patients be materially increased where the obstructions are only normal? In my illustration of the subject, I have in the foregoing pages produced a scientific theory justifying the practice, and subsequently exhibited a practice ratifying the theory, reciprocal agents of truth in favour of my cause. I do not consider myself entitled to credit in the matter. It was not I who restored the operation, nearly obsolete from the Middle Ages, to popularity in the nineteenth century; but neither do I deserve uncourteous aspersion for the honest exhibition of my experience."

Quarterly Return of the Mortality of the Metropolis.—In the thirteen weeks that ended on September 29th, 12,916 deaths were registered in London. That this mortality is relatively very low, will be manifest when it is added that last quarter fewer persons died by 1150 than in the same period of 1856, fewer by 1343 than in 1857, fewer by 1429 than in 1858, and fewer by 3094 than in 1859. It will further be observed that, as the population has increased, the smallest number of deaths was obtained from the largest population. In consequence of the coldness of the summer, and the unusual quantity of rain, the diarrhœa that carries off many hundreds of young children at that season was comparatively idle. The mean temperature of the air in the quarter was 56·8, which is five degrees less than the average of four corresponding quarters (1856-59), and six degrees less than it was in the same period of last year. In concurrence with this decrease of heat, the deaths from diarrhœa and cholera, which were 2920 in the same quarter of 1859, fell to 788 last quarter. Certain other epidemics visibly declined; for in the same periods small-pox numbered respectively 287 and 99; scarlatina, 778 and 471; diphtheria, 190 and 71; typhus, 502 and 311; dysentery, 104 and 28; and remittent fever, 33 and 13. But several diseases in the same class (the zymotic) were more fatal; for, comparing still the summer quarters of 1859-60, measles rose from 230 to 579; whooping-cough, from 243 to 350; rheumatism and rheumatic fever, from 58 to 76. Instead of 172 infants who died in the summer of last year from want of breast-milk, only 100 died last quarter; and instead of 69 from thrush, only 30. The greater coldness of the weather increased the mortality of pulmonary complaints: the deaths from bronchitis, which in four corresponding quarters ranged from 474 to 562, were in the quarter that has just passed 667; and those from pneumonia, which ranged from 377 to 581, were 606. Those from diseases of the heart also rose considerably, and were 610. From a review of the above results of the quarter, it will be obvious that a great portion, if not the whole, of that improvement in the public health which is implied in a reduction of the total mortality has fallen to children, and these chiefly of tender age. Measles was considerably more fatal in the Eastern group of districts than in any other of the five divisions.

Pauper Insanity.—A return has been issued by the Poor-law Board stating the number of paupers of unsound mind chargeable to the poor-rates on the 1st of January last in England and Wales, with the exception, at least, of a few places from which returns have not been received, and which had an aggregate population of about a quarter of a million at the last census. The number of paupers in receipt of relief was 850,896, and of these 31,543 were insane—namely, 22,378 lunatics, and 9165 idiots; so that the lunatics constituted 2·63 per cent. of the paupers, the idiots 1·08, and the two together—the insane—3·71 per cent., or no less than one in every 27 paupers. But it must not be supposed that one in every 27 of the English population is insane; that would be a terrible state of things: pauperism is caused by insanity, and the insane are immeasurably more numerous among paupers than in the general population. The return indicates a greater prevalence of pauper insanity in the south of England than in the north. While it shows also that in this country generally above two-thirds of the insane paupers are lunatics, and not one-third idiots, the variations in this proportion in different parts of the country will be found very remarkable. In Wales half the whole number of the insane are idiots, and the proportion is nearly as large in the south-eastern and south-western counties of England; while, on the other hand, in the Metropolis and the manufacturing districts the proportion of lunatics is larger, and of idiots less. There are three Welsh counties—Cardigan, Carnarvon, and Denbigh—each of which had a population at the last census but little more than half that of the parish of Manchester, but each of them has double the number of pauper idiots that Manchester has, though scarcely a third of its pauper lunatics. The comparison with Liverpool is still more striking; and London, which at the census had nearly five-and-twenty times the population of either of these Welsh counties, has not five times their number of idiots, but above forty times their number of lunatics. The return shows also that there are more women insane than men—17,647 to 13,896. The expense of the maintenance of these 31,543 insane paupers is stated to be nearly 10,000*l.* a week, or 520,000*l.* a year. Above half of them were lodged in lunatic asylums; and of the remainder half were in workhouses, 5195 resided with relatives, and a few in licensed houses or in lodgings.

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Untamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B.—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

THE MEDICAL CIRCULAR.

WEDNESDAY, OCTOBER 24, 1860.

THE STAFFS OF THE LONDON HOSPITALS.

The efforts made by this Journal to reform the system under which the Medical Staffs of our Hospitals are regulated, have been followed by considerable success. We cannot conscientiously accuse our Medical brethren of being indifferent to the principles of justice that we have inculcated. Our voice has been heard and responded to, and we have moulded a professional opinion that must ere long effect the accomplishment of all the objects which, some years since, we indicated. It is true that the vested interests of individuals eminent for talent, reputation, and influence still present a silent and pertinacious opposition to our efforts; but, on the other hand, the Medical press of the country is on our side, and the younger generation of Practitioners is unanimous as to the necessity of important changes.

When we commenced this crusade, we were privately encouraged by the assurances of many gentlemen that we were doing a good work, and our attention was directed to particular Hospitals where it was thought that the comments of a public journal might be followed by beneficial results. The evil was thus confessed; but the men whose interests were most deeply engaged in the issue of the controversy were precisely those who were most unwilling to give publicly their assistance to the cause. Who can be surprised? Few men are patriotic enough to pit their principles against their career. For some time, then, the MEDICAL CIRCULAR carried on the argument without help; but soon one and then another of our contemporaries took up the weapons as they fell from our hand, and the question of Hospital Reform is now fairly in the lists of controversy.

There are two points in particular in connection with this wide and important subject to which we shall now advert. Those points are, the retirement of Medical Officers from active duty at the age of sixty-five, and a large increase of the Staffs. Our readers will, no doubt, say that these are old subjects of debate in the CIRCULAR. Truly; but we shall never cease to revive them from time to time until our objects shall have been attained. The resignation of his appointment at the Venereal Hospital of Paris by M. Ricord, in accordance with the regulations in force in the French Capital, at the age of sixty-five, and after twenty-five years of brilliant and useful service, affords us a fresh opportunity for renewing the agitation of this subject.

Our Journal last week recorded the fact that our distinguished Surgical veteran, Mr Lawrence, has recently paid a visit to the French Hospitals. Let us profit by the occurrence, and for a moment contrast his position with that of M. Ricord. On the one hand is M. Ricord, in the plenitude of his mental power and the acme of his fame, retiring from a post to which his genius has given an unrivalled celebrity, in order that other men might come into his labours, so that the great principles he has taught might be either confirmed and extended by the exercise of a fresh mind upon similar facts, or be corrected as future experience might warrant; but that, in either case, the cause of Science should be advanced. With all his perspicacity of observation and lucidity of exposition, Ricord has done his work, and he has retired in favour of a younger head. On the other hand, we see Mr Lawrence, who is at least twelve years older than M. Ricord, who for thirty years has done nothing for Surgical Science, who, with all his talent, never possessed the originality of mind which has characterised the Frenchman, and whose name will not be associated with any great principle in Surgery or any remarkable improvement of the art, and who is now by natural laws nearly superannuated from active duty—nevertheless clinging to his office with the pertinacity of a young man who has a fortune to make and a reputation to achieve. Even if Mr Lawrence were in the vigour of his intellect, we should object to his retention of office; but inasmuch as for very many years he has been to Science nothing but a name, we must protest loudly against his continued incumbency of such an important post.

In every Hospital of this country, there should be a law requiring the members of the Medical Staff to retire at sixty-five years of age. Although such a law might press at first with some unfairness upon a few of the present holders of office—and in whose favour exceptions might be made—yet the result would be that men would be elected to responsible duties at an earlier age, that the patients and pupils would have the benefit of their talents and energies in the prime of their manhood, and that there would be a quicker circulation of honours and emoluments among the rising members of the Profession. What is the case now? Many able men pass away their lives as Assistant-Surgeons until nearly sixty years old, being thus most unjustly deprived of those opportunities of practising and operating, by which means alone good Surgeons can be made, and until their energies have lost their spring, and the ambition to struggle to a first place in the ranks of Professional honour has suffered extinction. The wrong is further increased by the fact that, with rare exceptions, an Assistant-Surgeon to an Hospital never takes a lead as a Private Practitioner, and he is consequently kept poor by the selfish system which has already victimised his reputation.

Again, is it not the fact that the limited number of men constituting our Hospital Staffs bears no comparison to the large amount of duty they are appointed to discharge? We have frequently resorted to numerical calculations to convince our readers of the inadequate arrangements for attendance upon the sick; and we observed, a few weeks since, an article in one of our contemporaries in which the same method of exposing the anomaly was adopted. Another contemporary has adverted to another view of this matter, and has pointed out that it is impossible to carry out a proper system of Clinical Instruction in our Hospitals, in consequence of the smallness of the Medical Staffs. This is perfectly true. Clinical teaching, in its strict sense, does not exist in this Metropolis. We would say that a pupil should be *ground* at the bedside of the patient. If a Medical or Surgical Officer were appointed to each ward, or every twenty or thirty beds, he would have time to select some of his worst cases, and daily to demonstrate to his class the symptomological and pathological phenomena they might present. The stethoscope, the balance, the microscope, and whatever else might be necessary to explain the case, would be resorted to; and thus we should see instituted an effective system of Clinical teaching, and the grinder's occupation of inculcating words without meaning would be gone. Such a system, however, could not be carried out unless the numbers of the Staffs were largely increased. We must also add, that in order to encourage the labourer, a more equitable adjustment of the fees would be necessary. We have on previous occasions spoken upon this topic; but we advert to it now because there cannot be a satisfactory reform without the recognition of this condition. A distribution of duty should be attended by a distribution of emoluments. Under the present system, the lion's share of the fees goes to a few of the elders, who cling to their offices mainly, if not altogether, for the sake of their fees. Thus it is that one injustice breeds another.

We feel assured that the leading points in the Reform we desiderate will at no distant time be accomplished. Since we opened this question, we have seen the principle of superannuation at sixty-five years of age adopted in the Public Services; we have seen a

moderate extension of the Staffs granted in some of the London Hospitals, whilst in others the grades of Assistant-Physicians and Surgeons have been abolished; but the latter have been only concessions to a public demand, and not frank adoptions of a principle. We know, however, that the Governors themselves of the Hospitals are beginning to take an interest in this question; our own pages have contained several letters from gentlemen filling this influential position, and with their aid, and with that of the Press we have no doubt that we shall yet see a realisation of our demands.

SUMMARY OF THE WEEK.

MEDICAL STATISTICS OF THE PARIS HOSPITALS.

That which has been long desiderated in this country—viz., an organisation for collecting the facts, pathological and therapeutical, observed in our Hospitals, with a view to establish some authentic data for practice—is about to be carried out in Paris, under the auspices of the Director of Public Assistance. He will be aided by a Committee composed of the leading Physicians and Surgeons of the Hospitals. These gentlemen will prepare a plan upon which the proposed inquiries can be carried out. We have no doubt that the facts thus brought together from various fields of labour will prove, ultimately, to be of great value to Medical Science. The means it will afford of comparing, at regular intervals, the results of different modes of practice, will tend to prevent a protracted popularity for dangerous remedies. A similar system would be highly advantageous in this country, and has indeed been proposed. It could never be satisfactorily carried out, however, without the frank co-operation of the Medical Officers of the several Hospitals. It is a duty which the Medical Council might be most properly called upon to discharge,—a duty not less honourable to them than useful to science.

METROPOLITAN SLAUGHTER-HOUSES.

We are glad to see Dr Gibbon, the Medical Officer of Health for the Holborn District, offering a resistance to the establishment of Slaughter-houses within the area of his duties. This is one of the evils which it is quite within the power of the Medical Officers effectually to repress. They should protest against a single new Slaughter-house being established in their several districts; and they should enjoin such regulations for existing ones, that the unwholesomeness they are calculated to produce would be reduced to its minimum amount. We are aware that the present law does not empower them to close Slaughter-houses; but, short of this, it gives them such extensive authority, that it must be their own fault if these places become offensive to public health. The sale of bad meat is another subject that requires the utmost vigilance on the part of the Medical Officers. The Committee over which Dr Challis presided, produced an able report upon the subject; and if each man, in his sphere, give effect to that Report, much public good will be done. We hope that we shall see the time when London will be supplied exclusively with country-killed meat; and that this result is very probable, may be deduced from the fact that, within the last twenty years, the increase of country-killed meat has been so great that two-thirds of the entire consumption of London is now of that quality. There is a hope, then, that in course of time the practice of intra-mural slaughtering will be abolished. It will, however, be necessary in that event to give increased attention to that which may be sent into the market, and prevent the sale of "slipped calves," measly pork, and such other marketable abominations as Dr Gibbon and his colleagues warn us against consuming.

THE HEALTH OF THE INDIAN ARMY.

The Royal Commissioners who were appointed some months ago are about to issue printed Forms for Returns of the Sanitary Condition of the European and Native Troops in India. These Forms are very elaborate, and relate to every circumstance of soil, climate, regimen, diet, habits, discipline, &c., that can in any way affect the health of soldiers. We hope that the good attained will bear a due relation to the minuteness of the inquisition.

SAVORY'S NARROW-NECKED POISON-BOTTLES.

We wish to ask our brethren if they have yet commenced the use of these admirable preventives of poisoning? These bottles are so constructed that they suffer the liquid to escape only drop by drop, and being polyangular in form, they are recognised immediately they are touched. If these bottles were in general use, both for the storing and dispensing of poisonous substances, it would be scarcely possible that such a thing as accidental poisoning could occur. Two or three cases of this nature having been reported within the last month in the papers, we have thought it necessary to point out how easily they may be prevented. Where ordinary care fails, extraordinary resources should be resorted to.

THE STUDENTS AND THE MEDICAL COUNCIL.

Parents and Pupils have been much puzzled to solve the enigmas propounded by Dr. Hawkins with reference to the "commencement of Professional Study." Formerly this period was understood to date from the period of apprenticeship; but, for some years past, an apprenticeship in relation to the important purposes of a Medical Education has been regarded as a great sham, and the Medical Council has determined, as we announced last week, that the "commencement of Professional Study" shall date from the first entrance at a Medical School. That there may be no mistake, however, we quote Dr Hawkins' letter upon the subject:

"Sir,—I cannot answer your inquiries more definitely than by saying that professional study is considered to commence with the first entrance and attendance at a recognised Hospital or Medical School. Apprenticeship or pupilage is not of itself professional study. All students, therefore, who do not enter and attend at a Medical School or Hospital during the ensuing Session 1860-61, will be obliged to conform to all the regulations of the Medical Council, which will come into operation before the commencement of the following Medical Session 1861-62—*i. e.*, they must pass an examination in general education, must then be registered by one or more of the bodies named in Schedule (A) of the Medical Act, and afterwards pursue professional studies during at least four years. "I am, &c.,

"Francis Hawkins."

VIVISECTIONS.

The extent to which vivisections may be practised for the sake of prosecuting physiological inquiries has often been debated by medical casuists. The only answer to the question thus raised is—necessity. Every pang that is caused beyond that which is absolutely necessary for eliciting truth, with a view to achieving some higher good for man, is gratuitous cruelty, and ought to be decisively condemned. Operations are sometimes resorted to in cases where the required facts could be as easily obtained by a close and vigilant observation of the ordinary phenomena of living function: these operations, being unnecessary, should be equally censured. Man's rights over the animal creation are limited by his necessities; and those necessities are judged by the importance of the end sought to be attained to the well-being of man, and by the conviction that the end can be attained in no other way. When, therefore, we hear that at Alfort, and other veterinary institutions in France, horses are deliberately tortured with the knife, not simply to lay bare to the eye of the inquirer some obscure vital action, but to demonstrate physiological propositions to the pupils in the ordinary course of their instruction, we cannot withhold an expression of indignation at such heedless barbarity. Humanity is offended at such violations of her laws and instincts. Happily, British physiologists are not liable to reproach on this ground; they observe more closely and experiment less rashly, and we have yet to learn that their contributions to science are in any degree inferior to those of the *savans* of France. We hope that the Veterinarians of Alfort will respect the protest of Humanity, and refrain from the guilt of these needless and cruel operations.

Paris Hospital Statistics.—A measure of great importance has just been adopted by the Committee of Management of the Hospitals of Paris—viz., the appointment of Commissioners to propose a plan of general registration of cases, comprising all the nosocomial establishments of the capital. These Commissioners have been chosen from amongst the Physicians and Surgeons of the Paris Hospitals.

HOSPITAL REPORTS.

GUY'S HOSPITAL.—Oct. 2nd.

Excision of Tumour (Internal) of Cheek—Amputation of Tumour of Testicle.—Mr Hilton.

Tumour of Inside of Cheek.

The patient was a man, about forty years of age. The tumour had been a long time forming—had increased lately, and become very troublesome. He was placed under chloroform. Mr Hilton made an incision through the left side of the cheek from the angle of the mouth nearly to the ramus of the jaw, thus exposing the tumour, which he removed. It had no connection with the tongue or gum, and was limited anteriorly to the side of cheek alone. Posteriorly it had got hold of pterygoid process, which could only be reached by actual cautery; and this encroachment was then burned away. The edges of wound of cheek were brought together by pins and suture. This case bore some faint resemblance to the malignant case we reported two weeks since, which was operated upon at the Great Northern Hospital, and which, we hear, has for the present healed up very favourably.

Amputation of Testicle.

The patient, about twenty years of age, has had tumour of testicle so long as he can remember anything. For many years it gradually increased in size, but latterly has increased more rapidly, become very painful, and its great weight rendered it on that account the more troublesome. Hydrocele formed, which had been tapped some short time since. An exploratory puncture had also been made a few days since, when only arterial blood in some quantity came away. Mr Hilton proposed to make an incision over the tumour, to obtain the opportunity of examining its nature, conditions, and attachments, and proceed according to circumstances. This was done, the patient being subjected to chloroform. He made a section longitudinally through integuments over the tumour, from above downwards. The integuments were very much stretched, and tightly invested by the tumour. Mr Hilton then dissected them completely all round from before to the posterior part of the tumour, which was as round as a ball. During the process, numerous vessels required to be secured. The tumour, as we have stated, was globular, and about three inches in diameter. Upon its clean removal, the spermatic sheath and testicle lay exposed, the whole length behind untouched, and perfectly free from disease. Mr Cooper Forster, in presence of Mr Birkett, made a section through the tumour, dividing it into two. Each divided surface presented a beautiful specimen of fibro-plastic formation. It was expected to prove fibro-recurrent, but a more beautiful specimen could not be met with of this kind. It was intended to take a drawing of it; but from the strong refraction of rays of light from its almost coloured surface, a cold drawing would but imperfectly do justice to this beautiful specimen.

We have availed ourselves of Mr Cleveland Smith's notes of the following case of

Paraplegia.

Ellen Bushel, æt. twenty-four, married, residing at Chaldon, Surrey, was admitted Aug. 9th, 1860, in Mary Ward, under the care of Dr Gull. She is a widow, having lost her husband about two years back. Her habits have been temperate. She has enjoyed good health. One year eight months ago she was in Redhill Infirmary, having paralysis of extensors of wrist and paraplegia. She had been exposed to a good deal of cold and wet. She stopped at the Infirmary eight months, at the expiration of which time she was able to move about, and had recovered the use of her wrist. She says she has been gradually getting better. On admission, her features were regular and small; complexion ruddy, tongue furred, appetite moderate, pulse hard and rapid. She has paralysis of extensors of toes. No loss of sensation; no affection of upper extremities and trunk. Has a slight pain in her left side, and, when walking, a pain across the lower part of her back. Heart-sounds normal, breathing good; but there is dulness of right apex, with crepitation and rhonchus. She coughs a good deal at night, expectorating a frothy mucus, no blood. No catamenia last three months.

August 11th.—Sparks of electricity to be taken from her back three times a week. Inf. cascar., ℥jss.; pulv. rhei salin., grs. xv.: bis die.

Aug. 14th.—She says she feels better; coughs a good deal.

Aug. 17th.—Coughs more at night; has slight nausea.

Aug. 22nd.—Not so well; good deal of pain in chest; perspiration profuse at night; giddiness; back feels weak.

Aug. 28th.—She went out, on account of not having the sparks of electricity taken from her back as ordered, the machine being out of order; and she did not find herself improved.

Paralysis.

We have availed ourselves of Mr Cleveland Smith's notes of the following case of paralysis:

Eliza Coates, æt. twenty-six, married, residing in Lambeth walk, was admitted July 18th, 1860, into Mary Ward, under the care of Dr Gull. She is of rather a ruddy complexion, with an anxious countenance. Her general health has been good. She has no children, but has had two miscarriages; the first, fifteen months back; the last, eleven months. Her catamenia has ceased these last three months. She has a dark areola round her nipples. Her family are all healthy. She has never had fits of any description, nor rheumatism, but has been of a nervous temperament. She was first taken, three months back, with a prickling pain in the bottom of her back, which, she says, went down her thighs. Soon afterwards she felt a similar pain in her arms. She gradually lost the use of her extremities, and for the last three weeks has had no use in them at all, not being capable of doing anything for herself. She has more movement in her left shoulder than right. Has some slight power over extensors and flexors of right forearm, but none over those of left. Sensation not impaired. Muscles wasted; and she complains of a tingling sensation, and as if the palm of the hand was drawn up. She can move her lower extremities freely, but complains of the tingling sensation in her knee-joint. Her legs are not swollen, but the muscles are wasted. She can, by assistance, support herself on her legs, and walk a little. Sphincter muscles not affected, and does not pass her water involuntarily. She has three or four circular spots on her upper extremities of the nature of *herpes*. Her bowels are constipated; lips parched; tongue furred; breathing good; heart-sounds normal. Ordered julepi rosæ, ℥vj.; quinæ disulph., gr. j.: singulis dosibus bis die. Middle diet.

July 23rd. — Bowels relieved; not so much fever, no loss of sight, no loss of speech.

July 25th.—Pulv. ipec. co. gr. x., om. n.; julepi iodinis, ℥j.: ter die.

Aug. 4th.—Pernit. pulv. om. n., et julep. Troubled with bright *muscæ volitantis*. Speech slightly affected, from the want of free labial movement; lower jaw somewhat stiff, and somewhat drawn up on one side; bladder distended. Troubled yesterday with formication in hands and feet. Can distinguish which finger is touched; sensation is good. Breathing mostly superior thoracic. Some purpura at upper part of chest. Pulse, 136; respiration, 36.

August 7th.—Spt. æth. sulph. co., ℳ xxij.; aq. camphoræ, ℥j.: 6tis horis. Wine, ℥j.

8th.—Died. No autopsy.

ST GEORGE'S HOSPITAL.—Oct. 4th.

Amputation—Removal of Necrosed Bone from Stump.—Mr Cutler. Excision of Tumour from Shoulder.—Mr Hewett.

Amputation.

The patient, a farmer about twenty-five years of age, fat, ruddy, and full of condition, had had strumous disease of right knee-joint for more than three years. The disease had become more active lately, and matter was suspected to have formed in knee-joint, and that cartilage and synovial membrane had become destroyed. Under influence of chloroform, circular incision at lower third of thigh was performed. Ligatures and usual dressings were applied. Mr Cutler said that Mr Hewett would dissect the amputated knee, and report the conditions of disease.

Necrosis of Stump.

The patient, a man about fifty years of age, had his right leg removed at lower third of thigh for strumous disease some months since. Mr Cutler made a section down to stump-end of femur through the old cicatrix. He then exposed the necrosed bone, and, with the assistance of pliers, broke away a portion of the dead bone. To effect this required great force and some strength, necrosed bone being very difficult to remove. Mr Cutler said he had no doubt that matter had formed higher up in shaft of femur. He could pass a probe now through the canaelli its whole length. If required to remove more diseased bone, it may now be easily reached and brought away.

Tumour of Shoulder.

The patient, a young woman about twenty years of age, said the tumour had been about six months from its first being noticed. It increased of late; she punctured it a short time since, when a small quantity of pus escaped. Under chloroform, Mr Hewett cut down upon it. It consisted of a very hard, dense cyst, which, when opened, discharged blood and pus. It was of an *atheromatous* character. He filled up the emptied cyst with lint, to induce inflammation of sides, and thus obtain granulation from secretion of adhesive lymph to fill up the cavity. Mr Hewett stated that he had had a similar tumour lately in private practice, situated near the elbow. The tumou formed on the tendon and fascia of biceps muscle, and caused great inconvenience. By practising the same plan upon it, he obliterated the cyst, and cured the tumour.

Oct. 18th.

Amputation of Arm.—Mr Hawkins. Removal of Tumour on side of Knee.—Mr Cutler.

Amputation of Arm.

Mr Hawkins gave a clinical lecture upon this subject on Tuesday last, at which we were present. This arm showed a curious manifestation of degeneration of tissues, which had been going on for twenty-two years. The forearm was greatly swelled, but the disease was mostly developed at the carpal extremity, and had made great ravages amongst the carpal, metacarpal, and phalangeal tissues. Two or three of the phalanges were destroyed and gone. The patient, a female about fifty years of age, was placed under chloroform. The cutaneous and subcutaneous cellular tissues were all implicated; and a condition of inflammation, with deposition of fibrous lymph, not of a purulent character, pervaded the structures below the elbow, more characteristic of elephantiasis than anything else to which we can compare it. Mr Hawkins operated at lower third of humerus by circular incision in the usual way. The disease did not extend into joint of elbow or above it. The arm will be made into a preparation for the museum.

Removal of Tumour on side of Knee-joint.

The patient, a female about thirty years of age, had suffered great torture and excruciating pain about the knee-joint for two years. At length her health began to give way, and this operation is the consequence. Mr Cutler made a longitudinal incision of about four inches in length on the inner aspect of femur towards the knee-joint. He dissected carefully through the tissues until he reached the cyst. The cyst was found well defined, and remarkably thick and dense. He at length arrived at a semi-pellucid transparent substance, which, from its shining, refractive surface, looked like jelly. A distinct white speck was visible through its coat, lying at the bottom of this mobile, almost luminous substance, which was about the size of a field-bean. The tumour was reddish-brown in colour, and must be characterised as an aqueous or hydatid cyst. It appeared to be only about three parts distended with fluid, and altogether of a curious and nondescript character. Mr Cutler said that from the intolerably painful nature of the tumour, he was led to suspect it was one of those painful fibrous tumours which are occasionally found in the neighbourhood of joints imbedded in the sheath of a nerve. Mr Hewett observed that about two months since, in private practice, a lady had an exactly similar tumour. This female had suffered greatly for a long time. The tumour was seated very deeply on the back of the elbow-joint. The cyst, when removed, presented exactly the same character as the one removed to-day. It was similar in colour, size, transparency, and the white, pearl-like, almost luminous spot seated at the bottom of it. All the circumstances were the same, it being seated deeply embedded in a strong cyst. But this tumour was broken in extraction. Nevertheless, it consisted, or was surrounded by another cyst, and the white pearly matter was seen to remain at the bottom. In this case,

phlegmonous inflammation set in after the operation, and extended up the length of the arm. Large communicating sinues formed, but in the end the patient did well. Mr Hewett suspected similar results would follow the operation of today, and that deep-seated suppuration would set in, and extend amongst the tissues and muscles of the thigh. This, he stated, was a common result in operating upon deep-seated tumours in the neighbourhood of joints.

KING'S COLLEGE.—Oct. 12, 1860.

CURE OF HERNIA.—MR WOOD.

Since our report of two operations for the cure of hernia last week, another has occurred on this date. This patient, a strong healthy man, had been unsuccessfully operated upon about six weeks since, at this hospital, by Mr Hulke. This circumstance rendered more care necessary, to obviate the tendency of hempen ligature, which he had used and had recommended, to set up suppurative inflammation, and to act somewhat as a seton. Mr Wood on this occasion again used strong copper wire, silvered, as in the last operation we described. He said the copper wire favoured the adhesive inflammation and the secretion of fibrinous lymph, which in this operation, and in these parts, was so desirable to be obtained, and thus avoided the occurrence of empyema. The object, he said, was to obtain, at the upper part of the canal and ring, a hard cicatrix. This, when induced in these parts, presented a firm barrier against the possibility of hernia occurring again. Upon making an incision to invaginate, he remarked how very strong and hard the old cicatrix had become. It was this firmness and hardness which was so desirable to be induced in these tissues of the invaginated superficial fascia, and the tendinous structures above, to give a solidity and unyielding strength, through which no future rupture or obtrusion of gut could pass. The metallic ligature is more irritating and stimulating, and induces lymph adhesion instead of pus; the latter is more apt to occur with use of hempen ligature. Mr Wood gave great care, by passing an additional ligature in this case between the external and internal rings.

CLINICAL CASES.

The following interesting case is at this time under Dr Walsh's treatment, at University College Hospital:

CHOREA (SECOND ATTACK) CAUSED BY FRIGHT—MITRAL REGURGITATION, DISAPPEARING IN COURSE OF A FEW DAYS—TREATMENT BY ZINC AND BELLADONNA — NO IMPROVEMENT —TREATMENT BY ANTIM. TART.

Henry Kinchet, æt. 14, admitted 26th Sept., 1860. Four or five years ago had attack of chorea, lasting about three months.

History.—Fortnight ago his master severely scolded and discharged him; and in a few hours the convulsive movements came on. No previous rheumatism.

Present State (Sept. 27).—Height about four feet. General appearance: stunted growth; dark-brown hair; large eyes; head notably long, anterior posterior diameter; tongue clean; bowels open daily; no history of worms; notably nervous excited manner; choreic movements, bilateral; voice low; words uttered with difficulty and hesitation; not anæmic.

Sept. 27th.—Cannot count six consecutively; movements do not continue during sleep, but sleep is very much disturbed. On waking, the movements are greatly augmented; he cries out. Blowing murmurs, first sound; point of greatest intensity, left apex. Urine healthy.

℞ Zinci sulph., gr. iij;
Ext. bellad., gr. ½.
Ft. pil. ter die sumendus.

Oct. 1.—No improvement; pupils slightly dilated.

℞ Zinci sulph., gr. v;
Ext. bellad., gr. ½.
Ter die sumendus.

Oct. 4th.—Pupils widely dilated; movements slightly increased, especially at night. Omitt. medicam.

℞ Ant. potass. tart., gr. ½. 4tis horis.

Oct. 6th.—Slight improvement; no sickness. Sit dosis.

℞ Ant. tart. P.l., gr. ½. 5tis horis.

Oct. 8th.—Decidedly improved; no murmur audible at apex; slight cough, with some sonorous rhonchus; both bases here, and there both anteriorly and posteriorly; movements less marked; he sleeps much better, and counts without hesitation.

[Further notes of this case will be given in our next number. The above notes were kindly communicated by Mr Holland, Physician's Assistant at University College Hospital.—REPORTER.]

MEDICAL SOCIETIES.

MEDICAL SOCIETY OF LONDON.

MONDAY, OCTOBER 15TH, 1860.

Dr Richardson read a paper

ON THE PHYSIOLOGICAL AND THERAPEUTICAL PROPERTIES OF THE PEROXIDE OF HYDROGEN.

This substance, which was discovered by Thénard in 1818, is, in fact, water charged with oxygen in the active state. In his paper, Dr Richardson took up the following points:—The history of the substance; its preparation, with special regard to pharmaceutical applications; its physical and chemical properties; its relations to ozone; its physiological properties; its therapeutical value.

It was obvious from the Author's description, that some obstacles lie in the way of the application of the peroxide of hydrogen for medicinal purposes, owing to the difficulty experienced in its manufacture. This difficulty, however, Dr Richardson greatly simplified; and we should infer that any experienced pharmaceutist could supply the medicine after a short acquaintance with the process of making it, as readily as quinine or other remedial bodies in preparing which time and care are the most important requisites. It was shown, indeed, that if perfectly pure peroxide of barium were supplied to the Profession, every practitioner in the country could make his own solution of oxygen as he might want it.

The description of the chemical and physical properties of peroxide of hydrogen was unusually interesting. Passing over the facts relating to the influence of inorganic bodies upon it, those bearing on organic matter strike one most forcibly. Thus blood freed from fibrine absorbs the oxygen from the peroxide, and, if it is venous blood, it becomes arterial, with a rise in the temperature. Washed fibrine and cellular tissue in the fresh state evolve the oxygen. Albumen, urea, gelatine, fibrous membrane, and skin, produce no change. Grape sugar, and indeed all the sugars brought into contact with it, become decomposed, and evolve carbonic acid. Starch undergoes the same modification.

These observations refer to animal substances recently used; but when putrefaction has commenced, then the oxygen of the peroxide seems to act on all alike, and to produce rapid disintegration.

Another curious fact relating to the peroxide was, that its oxidizing power was easily prevented by the presence of certain bodies having a wide extension of names, but analogous characters. Ammonia in vapour or solution, tobacco, hydrocyanic acid, solution of aconite, and, in short, all the narcotics that are miscible with water, possess this neutralising property; the permanency of the result being decided by the physical character of the agent employed.

The section of the paper on the relations of the peroxide of hydrogen to ozone was an interesting one, and indicated a careful study of this debated question. It is clear that Dr Richardson looks upon the two bodies as one and the same. If he has any doubt, it is to the effect that in peroxide of hydrogen there is not any affinity at all between the two elements, hydrogen and oxygen. We pass the matter over to dwell on the physiological actions of the peroxide. These seemed to arrange themselves into the following brief propositions:—A weak solution oxidises blood; but this effect can be stopped by the action of the alkaloids and of narcotics. The peroxide supports the life of fishes; but the body of the animal causes rapid evolution of the gas. The solution injected into the left side of the heart of an animal restores the irritability, but appears to have an opposite effect on the right side. Injected into the arterial system immediately after death, it seems to restore to the muscles the power of contracting on the application of an irritant. It suspends to a considerable extent post-mortem rigidity, and it reduces spasmodic action, excited by such bodies as ammonia and hydrocyanic acid. On the therapeutical value of this powerful agent, Dr Richardson did not dwell long, but reserved this essential point for another communication. He showed, however, that as an antidote to the alkaloidal poisons, as an external application to decomposing sores, as an internal remedy in fever, where the patient literally dies from deficient oxygen, and in diabetes, the medicine might be used with the very best promises of success. In the way of a pleasant acid drink, one could give, said Dr Richardson, to the typhus-stricken man 100 cubic inches of active oxygen per hour. In diabetes, one fact had been made out also by the Author, that, under the influence of the peroxide, the quantity of sugar at once became less, and the excretion of urine decreased in a relative degree. After illustrating his paper by experiment, Dr Richardson concluded by stating that, in placing it on the annals of the Society, he would guard himself, once and for all, from any exaggerated suggestions as to the value of this new remedial agent. The subject, indeed, was so novel, that after twelve months' study of it he had feared to use a sentence that had not been considered over and over again. He did not pretend to know all the properties of the peroxide. He did not bind himself inviolably to any opinion offered on the present occasion; nay, experience might show that the substance discussed in a medicinal sense took new and even different directions from those with which he had opened the argument. His own intentions and objects would be served if he did but call forth investigation and fact, let the course of events bend in whatever way they might.

Dr GARROD, on the part of the Meeting, returned the thanks of the Fellows to Dr Richardson for his interesting paper. He had no personal knowledge of the action of the peroxide of hydrogen as a therapeutic agent, and, therefore, could give no opinion about it. He thought the permanganate of potassia possessed qualities somewhat of an analogous nature, and the permanganates, he found, increased the quantity of sugar in diabetes. He would be very happy to forward Dr Richardson's inquiries and experiments in regard to the therapeutical action of peroxide of hydrogen in diabetics, by submitting cases in the hospital to his treatment, and would wish to know if the peroxides and permanganates acted in the same way. He had not himself given it in diabetes. He considered the permanganate of potassa to possess more oxygen than peroxide of manganese,—that it possessed many of the qualities and properties of the peroxide of hydrogen.

Dr THUDICHUM said, the peroxide of hydrogen of Thénard possessed the smell of chlorine, which was very strong, and that it could not be freed from chlorine. The stronger the peroxide, the more chlorine; the weaker, the less chlorine. In the proportions which he had prepared, and which Dr Richardson had also adopted, there was no taste whatever, and no presence whatever of chlorine. On the contrary, the other possessed acidity, and presence of chlorine; and he suggested that it should be made with simple sulphuric acid process. The question should be taken into consideration, why this evolves more oxygen than the other,—which, in short, evolves none. In the one is hydrochloric acid, in the other there is none. Dr Thudichum stated, that a gentleman of Bonn—a private gentleman, brother of a Professor of that University—had published a book on Fermentation, broaching a new theory. He supported his theory by 500 experiment upon bodies capable of absorbing oxygen, which came across other bodies to which, in turn, they relinquished oxygen. He said, that indigo might be considered to be a decomposer of oxygen. He reminded Dr Richardson that among hi numerous interesting experiments he had omitted to give one—namely, the decomposition of fibrines.

Dr LANKESTER we understood to say, that one atom contained oxygen, and that the other atom was in the condition of ozone. He said, one set of gentlemen considered, or insisted, that ozone was a peroxide of hydrogen, and another set that ozone is a product of oxygen. The question still remains unresolved, What is ozone? But there is every evidence existing that it is a condition of oxygen. He thought the peroxide of hydrogen valuable for communicating

oxygen gas. Ozone is so interesting a matter of inquiry, that it might form a subject for a paper of itself. He wondered that it had been so long neglected as a therapeutical agent. Dr Lankester then reverted to topics connected with the hygiène of cities and the country, the air of each producing different influences upon the passive secretions and excretions. He had no doubt the peroxide of hydrogen might be converted to Medical uses. He said Dr Franklin had considered ozone was a peroxyde of hydrogen.

Dr RICHARDSON, in reply, referred to Thénard's statements about chlorine. In solution, it occurred through the presence of sulphurous acid. Peroxide of hydrogen very strongly resembles chlorine, and it is doubtful whether chlorine water may not be used in place of peroxide of hydrogen. Chlorine water would be able to sustain life in fish. One immersed in it lived nineteen minutes longer than another in oxygen. We understood Dr Richardson to say, that fermentation was a process of oxidation. He considered that he had answered Dr Lankester's question relative to peroxide of manganese upon fibrine. Ozone cannot be ignored; he considered it to be a modification of oxygen. Dr Richardson went further into this part of the subject than our space will permit to follow, in connection with organic life. He would recommend the peroxide of hydrogen to be given as a therapeutical agent where oxygen is deficient, and given alone. He had great doubts of experiments made upon active men, following the active pursuits of life. In such cases the loss of carbonic acid is always uncertain. He reverted to experiments of injecting the jugular vein of a hare: it transformed the blood on the arterious side to venous colour, and it also produced fluidity of the blood. He considers the two substances, the permanganates and peroxide of hydrogen, to be diametrically opposite. He would gladly accept Dr Garrod's offer, for which he thanked him, but the peroxide took so much time to prepare.

Mr BULLOCK had given great attention and perseverance to the matter, and incurred great labour in the investigation. He agreed with Dr Lankester that, shortly, enterprising chemists would prepare the peroxide at a moderate charge. (*a*) He recommends its therapeutical use, not in connection with other medicines, but to be given alone. He considered peroxide of hydrogen and the permanganates quite different. In the permanganates the oxygen was combined; in peroxide it was substantially free. He believed that a direct relation might be discovered between chlorine and oxygen.

OUR NOTE BOOK.

ON THE QUESTION OF QUANTITIES IN TOXICOLOGY.

M. Louis Orfila says: When by chemical analysis the expert has determined the presence of poison either in the cadaver or in the matters vomited, he is required to declare whether the quantity of poison found or the quantity swallowed is sufficient to cause death, or produce the symptoms observed. In order to establish the sense in which the expert should reply to this question, we may take a rapid survey of the data upon which he should rely.

1. The whole quantity of a poisonous substance which has been swallowed is not absorbed, save in exceptional cases. A portion, usually the most considerable, is rejected by vomiting, or, after traversing the digestive canal, passes off by stool. When death takes place promptly, a portion may still be found in the canal. The remainder is absorbed, that is, it is carried into all the tissues. 2. The portion absorbed is not distributed uniformly through the various parts of the organism. Daily experience shows that, with the same weights, the liver always yields to analysis a much larger proportion of poison than all the other organs. 3. Elimination commences a short time after absorption, and the investigations which have been made up to the present time show that, as regards certain of these poisons, arsenic for example, it may be completed fifteen or twenty days after ingestion. It is therefore evident that the amount of poison remaining in the organs, where it has been carried by absorption, continues diminishing from the period of its ingestion; so that if life be sufficiently prolonged, the entire quantity of poison absorbed may have become eliminated prior to death. Thus, a month after the ingestion of an arsenical preparation, the organs will contain no trace of arsenic. Chemical search will not discover it, but yet death has been none the less the result of the disturbance which it has caused. It is obvious that the presence of the poisonous substance in the organism until the last moment is not necessary for the production of death. The blow was struck at an early period, diseased action has become developed under the influence of the poison, and death is the termination of such disease. 4. When the rejected matters are not handed over to the expert, and when the alimentary canal is completely empty, chemical research can only be directed to certain organs or portions of them. It is a rule for the first experts to retain a portion of the matters handed over to them for ulterior research. It is easy to understand, then, especially with the more or less considerable losses rendered unavoidable in so difficult an analysis, that the quantity found constitutes but a very small fraction of that which has been swallowed, or even of that which has been absorbed. 5. Finally, it is highly important to note that for no poison do we know the quantity sufficient to induce the accidents of poisoning. By observations, whose rarity restrains their significance, we know, in general, the limit beyond which doses should in general be regarded as poisons: but this limit is incontestably very superior to the reality. Thus, we know that 50 centigrammes of arsenic will induce poisoning in all cases, save in very rare exceptions; but no one can decide, in a given instance, whether five, ten, twelve, or fifteen centigrammes will not suffice to cause death. The action of poisons is so variable, and we are so little acquainted with the causes which give rise to their variance, that we cannot, without risking to expose ourselves to serious error, determine what is the minimum dose of a poison sufficient in a particular case to give rise to death or to the symptoms observed.

From the above data, it results—1. When the vomited matters and the stools have not been submitted to chemical analysis, it is impossible to ascertain even approximatively the quantity that has been swallowed, and, consequently, to declare whether the quantity ingested has been sufficient to cause death. The quantity absorbed, moreover, by reason of the unequal dissemination through the various organs, and the elimination which may have taken place, cannot be estimated by the amount found in certain organs or portions of organs. Such amount is but a minute fraction of the portion absorbed, which itself is but a fraction of the quantity swallowed. It may be insufficient to induce death, although the quantity ingested or even that absorbed may be more than sufficient. 2. If there have been neither vomiting nor stools, and if the digestive canal contain no poison, the quantity ingested has been all absorbed; and, for the above reasons, there is no means of judging by the quantity found of the amount which has been swallowed. 3. If the vomits and stools have been analysed, or if (in their absence) the matters contained in the canal comprised the whole of the poison swallowed, except the portion absorbed, it is possible to declare approximatively the amount ingested. In such a case it is desired to establish whether the quantity ingested is sufficient to determine death. It is only when the quantity swallowed has been much greater than that which would be really sufficient for this purpose that the expert can reply affirmatively. Under other circumstances, by reason of our ignorance concerning the conditions which modify the action of poisons, the greatest reserve is peremptory. The reasons for doubt, dependent upon the actual state of science, should be stated; and this conclusion brought out that, in general, even when the quantity ingested has been really larger than that which is necessary to induce death, we are still not in a condition to affirm that it has induced it.

It is very desirable that this question of quantity should be reduced to exacter proportions, and that it should no longer retain the exaggerated importance which is now attributed to it. The symptoms and the lesions of tissue, combined with the detection of poison in the organs, are the most valuable elements for forming a decision whether poisoning has taken place; while the question of quantity, so far from bringing out the truth, will only conceal it in the great majority of cases. When a poison exists in organs or in matters which should not contain it, its quantity, save in some exceptional cases, cannot be insisted upon as a proof of poisoning. The great bulk of crimes of this kind would escape detection if such a proof were considered necessary. In order to exhaust this subject of quantity, and of the conclusions to be arrived at by experts respecting it, we may state two particular cases in which dosage is daily referred to. 1. Has the poison which has been detected resulted from the substance having been administered medicinally? An instant's reflection will suffice to explain that except in the case wherein the poison has been found in the matters of the alimentary canal, the vomit, or the stools in quantities much larger than the highest therapeutical doses, the consideration of quantity will in no wise elucidate the problem. The portion absorbed, which, moreover, it is impossible to determine, will never be sufficiently considerable to allow of a sure deduction being made. 2. But it may be said, when we have to do with poisons which also exist in the animal economy in a normal state, is it not of service to have recourse to the consideration of quantity, in order to determine whether a poison discovered in the organs does not result rather from this normal combination than from a criminal introduction? When there exists in these organs a much larger quantity of poison than has been found in the normal condition (and thus far experience has taught us very little on this matter), we may be authorised to admit poisoning as probable, supposing that all other objections have been previously refuted. But when the amount discovered is not very considerable (and, judging from the preceding considerations, this will be the usual case, inasmuch as it can be only a portion of what has been absorbed), the embarrassment is just as great, and the question of quantity is of no significance.—'Gazette des Hôpitaux,' No. 60, and 'Medical Times and Gazette.'

(*a*) The peroxide of hydrogen may be procured of Bullock, and likewise of Perrins and Barnitt.

MEANS OF DETECTING THE PRESENCE OF ALCOHOL IN CHLOROFORM.

M. Lepage, a Pharmacien, has been examining the different methods which have been proposed for detecting the presence of alcohol in chloroform. He especially recommends two: the first, that namely of M. Soubeiran, is easy of application, but it is not very delicate, as it will not detect a smaller quantity than 5 to 6 per cent. It consists in shaking the chloroform in a tube with sweet oil of almonds: the mixture remains transparent if the chloroform is free from alcohol; in the contrary case it becomes more or less milky. The second process was proposed some time back by M. Russin. It consists in the employment of the binitrosulphide of iron, which is obtained by mixing a solution of nitrate of potash with sulphide of ammonium, then, while the mixture is being agitated, dropping in a solution of protosulphate of iron. The whole is boiled, evaporated to dryness, and treated with alcoholised ether, filtered, and the solution crystallized. It is stated by the author to be extremely delicate. The experiment is made by introducing several grammes of chloroform into a tube or stoppered bottle, then adding a few centigrammes of the binitrosulphide, shaking the mixture, and allowing it to settle. If the chloroform is pure, it remains clear as water; but if it contains alcohol, it assumes a brown tint, more or less deep, according to the proportion present. The presence of ether, aldehyd, methylic, and amylic alcohols, are also detected by this re-agent, which is excessively soluble in all these compounds.—'Pharmaceutical Journal.'

ATRASIA ORIS.

Many cases of the disease atrasia oris, or closure of the mouth, present themselves to the notice of those attending the medical charities of Calcutta. It would appear that there are two forms of this disease: one in which the mucous membrane covering the front of the ramus of the lower jaw has been inflamed, and subsequently contracting, causes closure of the teeth, without narrowing to any considerable degree the opening of the lips. If the history of these cases be traced, it will be found that they have generally resulted from the cutting of the last molar or wisdom tooth having caused the gum to inflame. The other kind of closure of the mouth results from the indiscriminate and excessive use of mercury by native practitioners. The ulceration of the mucous membrane lining the gums and checks succeeds to the ptyalism so produced, and, on the inflam-

mation subsiding, the opposed ulcerated surfaces unite and cause the jaws to be closed, and the opening of the mouth to be contracted. Both Dr Fayrer and Dr Partridge are accustomed to remedy the first accident in the same manner, by dividing the firm contracted band of mucous membrane with a knife (one of the tenotomy knives is generally found to be most convenient) and then forcing open the jaw by an extending trivalve speculum. With a little attention to dressing this plan generally succeeds. In the other species of atrasia oris a similar plan was at first adopted. The adhesions were divided by a narrow knife, the jaws forced open by the speculum if necessary, and lint dipped in oil was pushed in to separate the recently-cut surfaces. But the disease treated by this way alone had so great a tendency to relapse, that in the recent case, Dr Fayrer, in addition to the above, divided the skin at the angles of the mouth in a direction downwards and outwards; and though at first this occasioned a most lachrymose expression to the man's countenance, it ultimately perfectly succeeded, and he left the hospital cured.—'Indian Lancet.'

ENEMATA OF ETHER FOR ASCARIDES.

Dr Ogier Ward says: Having read in one of the periodicals that injections of sulphuric ether had been of great service in ascarides, I determined to recommend its use to a patient who had long been troubled with thread-worms. It was used as directed—viz., in a dose of fifteen drops in one ounce of water, which was retained in the rectum, the patient going to bed immediately afterwards. The result was that the patient, a lady, aged thirty-six, was not annoyed again for above a fortnight, and then only very slightly; and a repetition of the enema kept her free for three weeks longer; so that she flattered herself she had met with something like a cure for this troublesome complaint; and I also entertained a similar idea, having found the treatment successful in another case of ascarides in the adult. This patient, like the other, found the ether most effectual at first, but it is now quite useless; and, with this feeling, I thought it a subject of sufficient importance to bring under the notice of the late meeting. Since that time, however, I find the thread-worms have returned, though not in such numbers as formerly; but it is a curious fact that the ether seems now to have lost its effect in this case, the lady being compelled to use it every night. As this patient complained that she tasted the ether in a few minutes after the injection, I tried its effects upon myself one night just before bed-time. In three minutes by my watch, I perceived a strong taste of ether; and, on going to bed, my wife asked if I were unwell, and had been taking ether! Another effect of the ether injection is, that it causes the patient to sleep very heavily, which property may be turned to good account in cases of sleeplessness in persons who cannot bear opiates. From the history and treatment of many cases, I am convinced that the common notion, that the habitat of the oxyuris is in the rectum, is quite erroneous. A single injection of quassia, salt, or even cold water, will completely empty the rectum of all its denizens, so that a repetition will not bring away a single individual; and yet the next night they will be as numerous as ever. Indeed, the fact that persons liable to worms are most troubled after the bowels have acted, may be taken as a proof that they are carried down into the rectum together with the fæces; which, however, may not contain a single specimen. I am therefore disposed to believe that the thread-worm resides in the sigmoid flexure, or in the cells of the colon; and I am supported in this view by having often found that a repetition of an injection will bring away the ova without a single worm. If my idea be correct, our treatment should not be directed to removing them from the rectum, but to destroying them in their dwelling-places by aloes and other bitter substances mixed with the food of the patient.

I may add, as an instance of apparent communication of worms from one person to another, that the husband of one of the ladies has been more or less troubled with the thread-worms ever since his marriage, seventeen or eighteen years ago. He has used the ether once, with the effect of relieving himself for some weeks from the ascarides; and though they have returned, yet they have given him so little annoyance that he has not cared to repeat the ether injection, as he dislikes its smell and taste.—'Brit. Med. Journ.'

SPONTANEOUS DISAPPEARANCE OF UTERINE POLYPI.

A recent case of a woman who had entered the Charité Hospital, in order to be operated upon for uterine polypus, and who was found at the time of operating to have lost her disease, gave occasion to M. Velpeau to state to his class that he had so frequently met with instances in which uterine polypi had disappeared spontaneously, either in consequence of suppuration, withering away, or even by resolution, that he would advise his pupils never to be in haste to operate in such cases, unless serious hæmorrhages or other accidents rendered the doing so a matter of urgency. A still more common circumstance sanctions temporization — viz., the disposition these polypi often manifest to become stationary, the hæmorrhages, which really constituted all their gravity, after a while ceasing, and the patient getting accustomed to their presence.—'Gazette des Hôpitaux,' No. 33, and 'Medical Times and Gazette.'

STATISTICS OF INSANITY IN THE UNITED STATES.

Dr Richard Dunglison says the census of 1850, and the Reports of Institutions for the Insane, furnish the materials for Dr Dunglison's essay. The first of these, from its imperfect character, affords but little useful information. However, by it, it appears that in every 100,000 of the population there are 67 insane, 68 idiots, 42 blind, and 42 deaf mutes. While deaf-mutism prevails more among the native than among the foreign population, insanity is far more prevalent among the foreign-born than among the native-born population. In the New England States, however, the proportion is nearly the same for both. Insanity is far more prevalent among the white and free coloured population than among the slaves, a difference to which the comparative absence of intemperance among the latter probably much contributes. As to the question of the increase of insanity in the United States, the Author declares that, although it is stated to be considerable, it cannot positively be affirmed to be so, owing to the discrepancies in the censuses of 1840 and 1850.

The information derivable from the Institutions for the Insane seems to be more reliable; and the Author has obtained returns from 51 of these establishments. The following are some of the results of their examination:—

1. *Sex of the Insane.*—Of 48,995 patients, 25,593 were of the male, and 23,402 of the female sex. Dr Jarvis, in 1850, concluded, from the examination of the statistics of 21 American asylums, furnishing 24,573 cases, that the proportion of insane males to females was 121 to 100; but, according to the Author's researches, founded upon nearly 50,000 cases, there are found 100 females to 109 males in asylums.

2. *Age at which Insanity first appears.*—This point is omitted to be stated in so many of the reports, that the Author is obliged to draw his deductions from 12,472 cases only; and from these it appears that more than 75 per cent. became insane between 20 and 50 years of age, while it seems highly probable that a greater number became so between 20 and 25 than during any other quinquennial period. But comparing the figures with the numbers of the population at given ages, it is found that the ages between 30 and 40 are those which are most liable to insanity. Comparing the two sexes with each other, it is found that men are more liable under 20, females from 20 to 30, both sexes alike between 30 and 40, females decidedly more liable between 40 and 50, and 50 and 60, while males assume a decided preponderance after 60.

3. *Marriage.*—From the records of 20 Institutions, this particular is thus specified in 25,721 cases: single, 12,462; married, 11,150; widowed, 2,092; and divorced, 17. A larger proportion of insane married females to the whole number of insane females exists, than is the case with males; the single males exist in a far larger proportion than the single females, and the widows are far more numerous than the widowers. Thus, of every 1,000 males, 555 were single, 393 married, and 51 widowed; and of every 1,000 females, 429 were single, 436 married, and 135 widowed.

4. *Occupations.* — Examining 7329 cases in which the occupation prior to the attack is stated, it is found that professional pursuits—especially the learned professions—are more liable to insanity than those not characterised by great mental tension; while the quiet life of the agriculturist is far less productive of the disease than is the harassed condition of the commercial world. The professional classes, compared with each other, observe the following order: artists, druggists, students, teachers, lawyers, physicians, dentists, clergymen, musicians, and engineers.

It must be remarked, however, that the total number of occupations returned is too small to furnish any trustworthy criterion of the comparative liability of these respective occupations.

5. *Hereditariness.*—Upon this interesting topic there is scarcely any information supplied by the Reports.

6. *Exciting Causes.*—The Author states that he has taken much trouble in classifying the moral and physical causes of insanity in 11,259 cases. Among *moral* causes are domestic difficulties, religious anxiety, political excitement, intense mental application; and among the *physical* causes are intemperance, ill-health, epilepsy, sensuality, &c. "It will be seen by the following table that the physical causes predominate over the moral,—a fact which is denied as probable when applied to many of the European institutions, but yet which has been previously recognised as true in regard to our own Insane Hospitals.' The Author places 4649 of his 11,259 cases under the column of moral causes, and 6610 under that of physical causes. "We cannot point out here the great defects of any such system of classification, but refer now merely to the fact that the moral causes constitute only two-fifths, and the physical causes three-fifths of the whole number of causes above given. A glance at the table shows the order in which causes, taken as a whole, and not as divided into moral and physical, are arranged as exciting to insanity, and exhibits that ill-health and intemperance rank first, domestic troubles and griefs next in order, next the conditions peculiar to women, &c." Of the 11,259 cases, the insanity is attributed to disappointment in love, ambition, &c., in 576; the loss of friends, in 585; to vicious habits and indulgences, in 514; to wounds and blows, in 250; to excessive study or application to business, in 165; to fear, in 126; to excessive use of opium, tobacco, &c., in 129; to exposure and loss of sleep, in 123; and to spiritualism, in 94. *Sex* exerts an important influence in the distribution of moral and physical causes. Thus, of 3118 moral causes in which the sex is stated, 1585, or 51 per cent., were females, and 1533, or 49 per cent., for males. "If we omit from the list of causes of insanity, financial difficulties, politics, and application to business, which are almost exclusively sources of insanity to males, we shall find, in the more delicate emotions and passions, that woman becomes insane from moral causes in 57 cases per cent., while man only suffers in 43 cases. The reverse is true of physical causes, and *à fortiori*, if we exclude from consideration diseases peculiar to females. Including all the causes of this class in both sexes, the males are to the females as 53 to 47, and, excluding the diseases of women, a proportion exists of 64 males to 34 females."

7. *Forms of Insanity.*—In 7,322 cases the following proportion of the various forms existed:—Mania, 3,789, or 51·7 per cent.; melancholia, 1,366, or 18·7; dementia, 1,265, or 17·3; monomania, 902, or 12·3. Examining the figures according to *sex*, it is found that, while each sex is attacked with mania in an equal proportion, men are more often the subjects of dementia than women, and the latter suffer more from melancholia.

8. *Influence of Season upon Admissions.*—Of 21,072 cases there were 20·6 per cent. admitted during the winter months, 26·6 during the spring, 29·2 during the summer, and 23·4 during the autumn months. May and June are the months which take the precedence of all the others.

9. *Duration prior to Admission.*—The details of 10,304 cases furnish the fact, that 60 per cent. of the cases admitted had been insane only for a few months, the majority being less than 6, and a few ranging from 6 to 12 months; while more than a quarter of the cases (about 2,600) have been insane from 1 to 5 years.

10. *Recoveries.*—After commenting upon the impossibility of obtaining accurate returns in

respect to the completeness of recovery and the proportionate mortality, the Author states that, in 15,235 cases *discharged* from American asylums, the recoveries were returned at 6,549, or 42·9 per cent.; while, in 58,607 cases *admitted* into thirty-three asylums, the number of recoveries was 24,937, or 42·5 per cent. Of 10,679 cases admitted, the proportion of females restored was 44·8 per cent. to 43·0 per cent. of the males; and of 17,838 discharged, the recoveries were 45·7 females, 44·5 males. "Recovery is, therefore, more probable among females than among males. This depends upon the form of the attack, &c., and sometimes on revolutions in the female system, which produce happy changes when the resources of Medical art have been ineffectual. Women suffer more from melancholia than men, while the latter are more subject to dementia. The latter being in the majority of cases incurable, some reason seems to exist in this fact why the female sex should recover more often from insanity than the male." The influence of the *form* of insanity on the recovery is seen in 6,306 cases, among which the examples of mania cured amounted to 73·2 per cent.; of monomania, to 59·2; of melancholia, to 55·8; and of dementia, to 16·6 per cent. *Duration*, too, has much to do with the prospect of recovery. Thus, in one institution, while the chronic cases only furnished 21 per cent. of recoveries, the recent cases furnished 61 per cent.

11. *Mortality.*—"In 33 of the United States institutions, the number of deaths based upon 56,405 *admissions* was 8638, or 15·3 per cent.; while in 15,235 cases *discharged* from 21 asylums, 3256, or 21·3 per cent., died. One reason of this disparity between the admissions and the discharges is obvious—a large number of those cases which have undergone no improvement remain in an asylum, and do not therefore swell the list of discharges. Compared with the recoveries, we have the following favourable or fatal results in a corresponding number of cases. Of those admitted 42·5 per cent. recovered, 15·3 died; and of those discharged, 42·9 recovered, and 21·3 died." The *sex* is given in 3557 deaths as occurring in 18,594 admissions, as follows:—20 per cent. in the male, and 18·1 in the female admissions; and in 2631 deaths, occurring in 11,857 discharges, 22·5 per cent. were male, and 21·7 per cent. female. In either mode of viewing the mortality, that of males was the larger. As to the *causes of death* in nearly 2100 cases, in 677, or nearly five-sixteenths, there were affections of the nervous system; more than two-eighths (613) were diseases of the digestive organs (this category being increased in some localities by the prevalence of the cholera); about the same proportion (604) consisted in morbid conditions of the respiratory apparatus, while fevers, accidents, suicides, &c. made up the rest.

15. *Recurrence of Insanity.*—The Author has been in a great measure baffled in his attempts at ascertaining what proportion of the cases admitted were not first attacks, but mere occurrences; while the statement, even when it is made, that the attack under observation is a first one, is not always to be relied upon. Of 5370 admissions at three institutions, 3790 (70·5 per cent.) are said to have been first attacks; while 1580 (or 29·4 per cent.) were other than first attacks. About 28 per cent. of the males were second and subsequent attacks, while the per-centage of females was 31. These returns cannot, however, be fully relied upon, so that deductions can only be very doubtfully made.—'North American Medico-Chirurgical Review,' July, pp. 656—692.

Births, Marriages, and Deaths.

BIRTHS.

KENT.—October 9, at Vienna villa, Ryde, Isle of Wight, the wife of Benjamin Archer Kent, M.D., of a son.

LEACH.—October 16, at Union street, Southwark, the wife of Henry Leach, Esq., M.R.C.S., of a daughter.

LEE.—October 14, at Savile row, the wife of Henry Lee, Esq., F.R.C.S., of a son.

PILKINGTON.—October 12, at Chorley, Lancashire, the wife of Wm. Pilkington, L.R.C.P. Edin., of a daughter.

ROGERS.—October 1, at Berners street, the wife of W. R. Rogers, M.D., of a daughter.

MARRIAGES.

BLACKMAN—WOODLEY.—October 17, at St John's Church, Brixton, Matthew Blackman, Esq., Surgeon, to Maria Louisa, third daughter the late Thomas Stamford Woodley, Esq., of Brixton, Surrey.

FISHWICK—BULLMORE.—October 16, at the Parish Church, Truro, Henry Fishwick, Esq., to Ellen, youngest daughter of W. H. Bullmore, M.D., and Surgeon to the Royal Cornwall and Devon Miners Artillery Militia.

DEATHS.

BAGOT.—Recently, at Honduras, of cholera, Charles Bagot, M.B. Univ. Trin. Coll., Dub., L.R.C.S. Ire., Assistant-Surgeon 2nd West India Regiment.

BURROW.—October 8, at Ventnor, Isle of Wight, William Thomas Holme Burrow, of Settle, Yorkshire, M.R.C.S. Eng., L.S.A. Lond., aged 34.

COULSON.—October 6, at Wyke House, Isleworth, Ralph Coulson, of Ilkeston, Derbyshire, M.D. St Andrews, M.R.C.S. Eng.

DU GARD.—October 12, at Shrewsbury, Marianne, widow of the late Thomas Du Gard, M.D., aged 71.

GÖRGEN.—Recently, Dr Görgen, an Austrian Physician, and the proprietor of a Lunatic Asylum, in which Count Szechenyi committed suicide. Dr Görgen by this occurrence incurred the serious displeasure of the Government, and was removed from his position on the ground of negligence. From that time his health gradually declined, and he at length died insane.

JAMES.—October 12, at Clifton gardens, Marion, eldest daughter of the late Hugh James, M.D., of Spanish Town, Jamaica, in her 91st year.

MACANSH.—October 12, at Doune, Perthshire, Andrew Macansh, Surgeon R.N., (seniority November 10, 1813,) aged 73.

MASTERS.—September 3, in Pembroke parish, Bermuda, West Indies (his native place, after a very painful illness, Bezin Reece Masters, M.D.

RATHKE.—Dr Rathke, the celebrated Professor of Zoology and Medicine at the University of Königsberg, died of apoplexy on the eve of the day on which he was, as President, to open the Meeting of German Naturalists in that city.

SEXTON.—October 15, at Ravenscourt square, Hammersmith, Archibald Alison, son of George Sexton, M.A., M.D., &c., aged 4 years.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following Members having undergone the necessary examinations, were admitted Licentiates in Midwifery, at a meeting of the Board on the 17th inst.:—Alfred Coleman, Wandsworth; diploma of membership dated April 20, 1860; William Cooke, Tunbridge, Kent—April 5, 1822; Cooper Hayes Crawford, Stafford—March 7, 1856; Frederick Dawson, Islington—April 19, 1860; William Hicks Farrington, Ottery St Mary, Devon—April 15, 1859; Charles Grabham, Rochford, Essex—April 11, 1859; John Charles Harris, Chipping Norton—April 18, 1859; Robert Iliffe, Coventry—Aug. 2, 1860; Henry Colley March, Rochdale—April 20, 1860; Richard Hawes Metcalfe, Wensleydale—April 13, 1860; George Michael Nell, Colombo, Ceylon—March 14, 1859; John Smith Crosland Richards, Bedford square—Aug. 1, 1860; Barnard Edward Spaull, Hammersmith—April 6, 1856; William Williams, Penrhyn, Holyhead—Nov. 12, 1858.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of Medicine, and received certificates to practise, on Thursday, October 11th, 1860:—Octavius Dean, Manchester; Charles Furner, King's road, Brighton; Robert Hancock, Bath, Somerset; Charles Ferdinand Keele, Portswood, Southampton; Alfred Monckton, Brenchly, Kent; Eustace Henry Olive, Linton terrace, Hastings; Francis Samuel Worthington, Lowestoft, Suffolk. The following gentlemen also on the same day passed their first examination:—John Harward Hooper, Upton Warren, Worcestershire; Joseph Lees, Wolverhampton; Forbes Watson, Aldersgate street; Samuel White Duckworth Williams, Gloucester.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN IN LONDON AND ITS VICINITY.—The Half-yearly General Meeting of the members of this Society was held on October 10th. It appeared that during the first half of this year 38 widows and 22 children of former members had received half-yearly grants amounting to 869*l.*; besides grants towards self-maintenance to two children, 45*l.* A grant was specially made by this meeting of 30*l.* towards apprenticing an adult deaf-and-dumb son of a late member. Dr John Clarke having withdrawn from the office of Acting Treasurer, a warm vote of thanks was passed to him for his valuable services during the past five years. The following members were then elected Officers and Directors for the year ensuing:—President: Thomas Arthur Stone, Esq. Vice-Presidents: Martin Ware, Esq.; Everard A. Brande, Esq.; John Nussey, Esq.; Sir B. C. Brodie, Bt., F.R.S.; Peter M. Latham, M.D.; John Bacot, Esq.; Thomas Turner, M.D.; D. Henry Walne, Esq.; A. J. Sutherland, M.D., F.R.S.; Edward Tegart, Esq.; Ed. Stanley, Esq., F.R.S.; Geo. Burrows, M.D., F.R.S. Treasurers: John Miles, Esq.; James T. Ware, Esq.; G. Hamilton Roe, M.D. Directors: Robert Nairne, M.D.; William Cathrow, Esq.; Edgar Barker, Esq.; James Paget, Esq., F.R.S.; John Adams, Esq.; Fred. J. Farre, M.D.; A. B. Barnes, Esq.; Edward Dew, M.D.; John Love, Esq.; H. A. Pitman, M.D.; Chas. Collambell, Esq.; Benj. Travers, Esq.; B. G. Babington, M.D.; J. Wetherfield, Esq.; John J. Sawyer, Esq.; Thomas Brown, Esq.; C. J. B. Aldis, M.D.; Wm. Dickinson, Esq.; J. C. Salisbury, Esq.; Henry Blenkarne, Esq.; T. King Chambers, M.D.; John Clarke, M.D.; Daniel Scannell, Esq.; Prescott G. Hewett, Esq.

ASSOCIATION OF THE FELLOWS AND LICENTIATES OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS, IRELAND.—The following is a list of officers for the Session 1860-1:—*President*, Dr Corrigan.—*Vice-Presidents*, Drs O'Reilly and O'Brien Adams.—*Council*, Drs Henry Kennedy, Lombe Atthill, Edward B. Sinclair, Alfred H. McClintock, and Robert Law.—*Treasurer*, Dr George A. Kennedy.—*Secretary*, Dr William Moore.—The meetings of the Association are held in the College Hall (Sir P. Dun's Hospital), on the evenings of the first Wednesday in every month during the session, at eight o'clock.

A LIBERAL OFFER.—A London merchant, whose daughter has derived great benefit from the climate of Torquay, has offered to give 500*l.* towards the completion of the Hospital for Consumption, provided 1000*l.* be raised for the same purpose within a month.

THE EMPEROR OF FRANCE AND THE HOSPITALS OF ALGERIA.—On the 28th ult. the Emperor, whilst at Algiers, decreed that certain lands in the three provinces of the French possessions of Northern Africa should be given to the civil hospitals.

ROYAL COLLEGE OF SURGEONS.—In analysing the newly-published list of Fellows, &c., of this Institution, we find that 249 Members of the College have been admitted Fellows by examination—an excess of only 16 over the number of last year. The number of Honorary Fellows amounts to 1018, being an excess of only 25 over the number published last year. The gross number of Fellows now amounts to 1267; and of Members there appear to be nearly 14,000. The Licentiates in Midwifery now amount to 769—just 60 over the number of last year. The persons who have received the Certificate of Qualification in Dental Surgery during the past year, and now for the first time published in the list of Fellows, Members, and Licentiates in Midwifery, amount to exactly 100.

TORQUAY INFIRMARY.—A wing has lately been added to this Infirmary for the reception of fever patients. Upwards of 1500 cubic feet of space is allowed for each patient. The wards are twenty-four feet wide and sixteen feet high, with windows carried up to within a foot of the ceiling on three sides, and the fourth is provided with ventilating screens of perforated zinc, controlled by flaps. In addition to this, an exhausting shaft passes over each line of beds above the ceiling, with ventilators at intervals, and these communicate with a flue carried up in the chimney stack. The heating is by open fire-places. The probable cost, including fittings and furniture, will be about 90*l.* per patient.

METROPOLITAN SLAUGHTERHOUSES.—Dr Gibbon, the Medical Officer of Health for the Holborn District, has presented a report to the District Board of Works from which we make the following extract:—"During the past fortnight, at your desire, I have given my attention to the slaughterhouses of the district. On a careful examination, I found that many of them had

lately been improved, in respect of their drainage and ventilation. Although some of them require slight repairs and alterations, as specified in the accompanying sheet, I believe that they are fully complied with. Notwithstanding the satisfactory state in which these establishments at present are, their presence in a densely-populated district must always be regarded as a serious sanitary evil. I regret, therefore, that Mr Cross, the large slaughterman of Red Lion alley, who has received notice that his present premises will be required for the Metropolitan Railway, has thought right to seek a licence to convert the Rose and Crown yard, 127 St John street, formerly used as a cattle-lair, into a slaughterhouse. Mr Cross is too good a man of business not to appreciate the value of cleanliness in conducting his extensive trade: he slaughters on the average upwards of 1,000 head of cattle every week. I must protest, on sanitary grounds, against the establishment of any fresh large abattoir, however well it may be conducted, in so crowded a neighbourhood. In this case there is no room for the usual pleas of the retail butcher for a slaughterhouse that he frequently wants,—a given joint at a short notice, and wants to slaughter for it especially; and that meat will not keep long enough in hot weather to bear the transit from a distant abattoir. Mr Cross slaughters not for any retail trade of his own, but for the wholesale salesmen of Newgate Market; and, in my opinion, his trade can be carried on with more advantage to himself, as well as to the public, in the spacious slaughterhouses connected with the New Cattle Market in Copenhagen fields. There is, I know, a very important objection felt, if not expressed, by slaughtermen to these abattoirs—viz., that they are constantly visited by City Markets and Slaughterhouse Inspectors, who have power and are specially appointed to seize any cattle or meat which are so diseased as to be unfit for human food. Now, we in this district have no power to seize such diseased meat unless it be exposed for sale in an open shop. When we see it in a private slaughterhouse, we are informed that it has been carefully slaughtered, and dressed for the use of pigs. Had we the power, I can assure you that there would be no lack of opportunity to seize slipped calves and cows in all stages of disease. When serving on a committee two or three years ago, to devise the best means of preventing the sale of unwholesome meat, I was struck by the evidence of the large number of unhealthy animals that are slaughtered for the London market. The conclusion I arrived at then was, that the consumption of such creatures for human food can only be avoided by a system of careful inspection by competent men, and by killing the total amount of meat required for the metropolis in some few authorized places where animals while living, and their organs after death, can be subjected to proper supervision. I do not intend these remarks to apply to Mr Cross, who generally kills first-class meat. However, this evil at present is so prevalent, and is fraught with such danger to the public health, that I trust your Board will hesitate before it sanctions such an application even from Mr Cross. According to the 55th section of the Building Act 1855, which provides—'That it shall not be lawful for any person to establish or newly carry on any such business, either in any building or vault in the open air, at a less distance than forty feet from any public way, or than fifty feet from any other such buildings of the first or dwelling-house class,' 18 & 19 *Vict. cap.* 122 *and* 55—this proposed slaughterhouse would be illegal, as it is within fifteen feet of the Charterhouse pensioners' dwellings, and within a less distance of the dwellings over Charterhouse mews. The carriageway to the Charterhouse Master's lodge and school passes close to the back wall of these premises. On these grounds, if on no other, I would recommend the Board to oppose the grant of this licence."

Queen's University in Ireland.—The Annual Meeting of the members of the Queen's University, for the purpose of conferring degrees, was held, with the usual formalities, on Friday the 12th inst. in St Patrick's Hall, Dublin Castle. Twenty-one gentlemen, including eight who had availed themselves of "a recent arrangement made by the Senate to facilitate the acquisition of Medical Degrees by Students who had completed the necessary courses of education, and might, for special objects in relation to the public service, desire to pass the required examination at the earliest period," were admitted by the Lord Chancellor of Ireland, Vice-Chancellor of the University, to the Degree of Doctor of Medicine. The following are the names of those thus admitted:—M.D.—James Valentine Browne, M.D., University of Aberdeen, *ad eundem;* Henry Burden, B.A., Belfast; William John Busteed, Cork; William H. B. Clapp, Cork; William Hill Climo, Galway; George Cooper, Cork; Richard B. Davidson, Belfast; Edward Divers, Galway; Usher Beere Eaton, Cork; Albert Augustus Gore, Galway and Cork; Francis Bernard Hurley, B.A., Galway; William H. Jones, Cork; William Kingsley, M.D., University of St Andrews, *ad eundem;* J. Henry Lawson, Galway and Cork; John Sampson Levis, Cork; Thomas B. Moriarty, B.A., Cork; Courtenay Nedwill, Belfast; Francis Ronayne O'Kearney, Cork; Matthias O'Keeffe, M.A., Cork; Richard Read, Cork; Isaac Cromie Saul, Belfast; Hugh Willis Thomson, Belfast; William James Wilson, Belfast. The following were announced as having passed the Previous Medical Examination:—Richard Barrett, Cork College; Acheson George Bartley, M.A., Belfast; the Hon. Barry J. Bingham; Edward R. Blackett; John R. Burke, Galway; Richard Carroll, Galway and Cork; John Norman Davis, Galway; Charles Evans, Galway; Valesius Gouldsbury, Galway; James Hutchinson, Galway; John Hamilton Moore, Galway; Robert L. Moorhead, Belfast; Stephen O'Sullivan, Cork; Robert Potter, Cork and Galway; John Henry Loftie Stoney, Galway; George Shannon, Belfast; James R. Swanton, Cork; Joseph Whitaker, Belfast. His Excellency the Lord-Lieutenant then bestowed the following Honours with the Degree of M.D.:—William H. Climo, Third in Order of Merit, Galway College; Edward Divers, Third in Order of Merit, Galway; John Sampson Levis, Third in Order of Merit, Cork.

Charity and Self-support.—A proposal to erect Baths and Washhouses at Cardiff has led to inquiries in other towns as to the working of these charities. The result, published in the 'Bristol Daily Post,' affords the following curious information, showing a pecuniary loss in every instance:

	Expenditure.	Receipts.	Loss.
Birmingham ..	..£2714 12 8	1752 10 4	962 2 4
Sunderland ..	.. 484 2 4	415 2 8	68 19 8
Do Hendon Road	.. 882 18 4	650 6 2	232 12 3
Bristol ..	.. 667 6 11	581 3 2	86 3 9
Halifax ..	.. 703 5 3	487 18 4	215 6 11
St George's, Liverpool	2501 19 0	1321 4 0	1180 0 0
Paul Street, do.	.. 1587 5 5	640 11 5	946 11 0
Cornwall Street, do.	3927 11 0	2333 5 10	1594 5 2
Hull	.. ——	——	332 2 6

Upon this the 'Journal of Gas Lighting' remarks that "Washhouses must be considered strictly as charitable institutions, and cannot be made self-supporting. But if they are charities, then the charges, the arrangements, and regulations must be directed toward inducing the class to use them who need them. They are certainly not needed in small towns where the population is not crowded together. They certainly ought not to be provided in any town for the use of the well-to-do. There are instances in which it will do as much good to give a ticket for washing as a ticket for soup. We suspect that the failure of a public washhouse will often turn on the management. Baths stand on a different ground. There is a steady increase in the love for bathing in all classes of English town residents. The taste, like all other tastes in England, descends. Thousands of workpeople could never wash at all in great towns without the use of public baths. We must be patient in teaching the working classes new ways. There is also a certain advantageous effect produced on the public mind by the construction of such buildings as baths and washhouses. The poorer classes see that they are cared for, and this is a moral consideration not to be forgotten."

The 'Indian Lancet' advocates the French system of the licensing and medical inspection of bazaar women, and the establishment of Lock Hospitals for the prevention of the frightful curse of venereal disease in the European Army. In all discussions as to the amalgamation and organisation, this point has been steadily ignored. The question *must* be grappled with. God's law is marriage, and till that is obeyed no system of prevention will succeed.

A Volunteer on his Mettle.—At the Banff County Meeting, Mr Gordon, of Cairnfield, in reference to the order of sederunt, said it was a question what might be the appropriate designation for Dr Whyte—whether they should not set him down as Captain Whyte, seeing he was present in the uniform of his Artillery Corps. (Laughter.) Dr Whyte—Mr Gordon, of Cairnfield, will be pleased to understand that, whether I am here in uniform or not, I have taken University degrees, which give me a right to take precedence of Mr Gordon, or any gentleman here, with the exception of Sir George Abercromby. (Laughter.) I insist on having my title of Doctor, and by virtue of that I rank next to Sir George Abercromby at this meeting in point of precedence, and insist on having that preference. (Laughter.) Mr Gordon observed that he certainly never intended, and never would offer, any insult to any of her Majesty's officers. (Laughter.)

We extract the following from the 'Carlisle Journal' of Friday last: "The Lunatic Asylum.—The appointment of Medical Superintendent of the new Asylum at Garlands was made on Wednesday by the Committee appointed at last Quarter Sessions. From a great number of candidates a list of eight had been selected, and these gentlemen were invited to meet the Committee on Wednesday at the Grand Jury room in this city. Six attended; and the choice of the Committee fell upon Dr Kirkman, at present Assistant-Superintendent of the Suffolk Asylum, of which his father has for many years been Superintendent. The unsuccessful candidates, and their friends, were of course disappointed, but we have not heard that there is any reason to suppose that the appointment was made on other than fair and honest grounds. There was, however, some justifiable dissatisfaction at the shabbiness of the magistrates in refusing to pay the expenses, or part of the expenses, of the candidates whom they invited to come to Carlisle. Hundreds of pounds have been shamefully wasted by them upon the building, and we can only hope it is compunction for this which has drawn them into this paltry saving."

The 'Indian Lancet' contains a notice by Dr Frazer, of H.M.'s 88th, of the boil or ulcer peculiar to the districts of Delhi, and called by the natives 'Aurungzebe' after that emperor, who was a victim to it. In ten months, 114 soldiers of H.M.'s 88th, besides officers, women, and children, were afflicted with Delhi boils all over the body. In three months after their arrival in the city, the sores made their appearance. They disfigure the appearance of the patient, and appear on the same spot, in many cases, four times, leaving behind the trace of a deep wound. Dr Frazer agrees with the theory of the natives, which ascribes them to the water of the district impregnated with salts. A similar disease appears in Sind and Mooltan, where the water is the same. It appears most after the rains, when the wells have been filled with water percolating through the saline soil.—'Friend of India.'

The will of Thomas Addison, M.D., of Berkeley square, late Consulting Physician to Guy's Hospital, was admitted to probate on the 4th inst., and the personalty sworn under 30,000*l.* by one of the executors—namely, John Addison, Esq., of Banks House, Cumberland, the testator's brother; power being reserved to Alfred Brooke Barnes, Esq., Surgeon, of King's road, Chelsea, also an executor. To his relict he has bequeathed his freehold estate and residence at Brighton, together with the furniture, and has left her an annuity of 350*l.*, and his shares in the Indemnity Mutual Marine Assurance Company; and to her son and daughter he has left an annuity of 100*l.*; these annuities to be free of legacy duty. The presentation of plate made to him from various parties, both public and private, he leaves to his said brother, to be held by him as heirlooms in the family. He appoints his said brother, John Addison, Esq., residuary legatee of his estate, real and personal. The will bears date September 26, 1855, and a codicil in 1858.

The State of "The Diarrhœal Districts of England."—Diarrhœal diseases, though generally preventible, are increasing in this country, and their epidemic aggravations are sometimes of appalling severity. It has been truly said, that probably since the days of the great plague, death has never so scared an English population as in the cholera epidemic of Newcastle of 1853, and in the Golden-square outbreak in 1854. Now, diarrhœal diseases prevail with extraordinary inequality in different parts of the country; and it is to be recollected that

the endemic causes of diarrhœa are the causes of much other disease. It was therefore determined to begin authorized local inquiries in cases of excessive preventable mortality with an examination of the disproportionate localization of diarrhœa in particular districts. Accordingly, eight large towns were selected last year which habitually suffer a very great excess of mortality from this cause, and Dr Greenhow was commissioned, as a temporary inspector, to inquire into their sanitary condition. The towns are Coventry, Manchester and Salford, Nottingham, Birmingham, Dudley, Leeds, Wolverhampton, and Merthyr Tydvil. It was necessary to find a fair standard for the rate of diarrhœal disease. There are districts of England in which endemic diarrhœa is unknown; but, leaving these, it was thought reasonable to take two considerable groups of contiguous rural districts, one in the north, and the other in the south—districts by no means so faultless as to be unapproachable, but in them the annual average diarrhœal death-rate during the years 1847-1855 was only 29 in 100,000 of the population. In the eight towns just named the mortality from this cause is from three to nine times as great. In all of them Dr Greenhow found it coincident with one or other of these two circumstances—the habitual drinking of impure water, or the tainting of the atmosphere with the products of organic decomposition, especially of human refuse. In other words, in districts which suffer from high diarrhœal death-rates, the population either breathe or drink a large amount of putrefying animal refuse. He traces street by street, showing how diarrhœa, visiting cleanly districts but slightly, is especially grouped round those spots where there is an accumulation of night-soil infecting the air in the midst of a dense population, or so placed that the exhalations penetrate into the houses, or can be but slowly dispersed into the general atmosphere. The comparative immunity of other districts resembling these in all respects, save the absence of this fæcal impurity, is found to be so constant, that it seems impossible not to admit the relationship as one of cause and effect; and the Medical men affirm that diarrhœal disease is not only more prevalent, but also more unmanageable, in ill-conditioned places. Without producing the unsavoury details which Dr Greenhow has had to record, a single sentence concerning Birmingham tells the tale of all the towns:—"Not only has diarrhœa most prevailed, and proved most fatal, in streets where these causes of atmospheric impurity existed; but, as has been shown in the history of particular streets and courts, it has selected as its victims persons much exposed to these causes, to the comparative exclusion of others." It has often been shown that these causes produce diarrhœa, but their investigation has hitherto been limited to epidemic epochs, and especially visitations of cholera; it is here demonstrated that their influence is more constant; and Dr Greenhow remarks that the occurrence of epidemic epoch may arise from peculiarities of season giving greater efficacy to these local causes, or possibly from the products of decomposition at such periods being different from those at ordinary times. How preventable this disease commonly is, may be judged from the success of sanitary improvements in almost all those very districts in reducing the local prevalence of diarrhœa. But, though much has been done, the report shows that it is very far from enough; and it may surely be hoped that the authorities of these towns will take means for removing from their administration "the reproach of preventable but unprevented disease." There is a motive that should especially stir the great manufacturers, whose unparalleled wealth is acquired in these districts. A very large portion of the deaths from diarrhœa are those of infants: above half this mortality occurs under one year old; and this is attributable, partly at all events, to the extensive factory employment of female labour. A mother has to leave her infant at three or five weeks old to the care of a little child or of a hired nurse, and hurry home heated to breakfast and to dinner, with little time in which to nurse her child and get her own food, and in her absence her child is fed on unsuitable diet, and has its cries of hunger and distress quieted by those opiates which are in such request at the centres of our manufacturing industry. Mr Simon remarks that the evil may be averted, or at least greatly mitigated, by arrangements which, however, the labouring classes themselves have not the power of organizing.—'Medical Times and Gazette.'

APPOINTMENTS FOR THE WEEK.

Wednesday, October 24.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, October 25.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.

London Surgical Home.—2 p.m.

Friday, October 26.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, October 27.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, October 29.

Operations at the Royal Free Hospital, 2 p.m.; Metropolitan Free Hospital, 2 p.m.

MEDICAL SOCIETY OF LONDON.—8½ p.m.

Tuesday, October 30.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

The Reformed Roman or Oriental Baths of Britain. Second Edition. By Jas. Tucker, M.D.

On Myalgia. By Thos. Inman, M.D. Second Edition. London: John Churchill.

The Volunteer's Manual of Health, &c. By Henry Smith, M.D. London: Ward and Lock.

On the Reparative Process in Human Tendons. By Wm. Adams, F.R.C.S. London: John Churchill.

Further Observations on Several Parts of Surgery, &c. By Benjamin Travers, F.R.C.S. London: Longman and Co.

Case of Ectopia Cordis. By Edward Daniell, Esq. London: T. Richards.

NOTICES TO CORRESPONDENTS.

H. H.—You ought to apply to have the qualification registered. A fee of five shillings must be paid.

CHIRURGUS.—The tungstate of soda is reputed to be the best agent for the protection of dresses against fire. It will not obviate their destruction, but it will prevent a blaze, and so give time for the extrication of the person in jeopardy. It is said that the tungstate of soda does not injure the material or interfere with the colour. There are more than 3,000 deaths from burning registered annually in this country. The use of a preventive means becomes, therefore, a matter of importance.

Mr HARRISON.—1st. No.—2nd. No.

Mr TURNER is thanked.

Dr WALKER.—We are obliged by your communication.

FUMUS.—We have no room for your *jeu d'esprit*,—especially as it is evident to us that your inspiration was derived from a narcotic source, and it might possibly produce a kindred effect upon your readers. Sir Benjamin Brodie did not absolutely condemn smoking; he only protested against its abuse.

IOTA.—You will come under the existing regulations.

KING'S COLLEGE. — 1st. Certainly. —2nd. It is a matter of convenience.

Mr HENRY E. B.—Mr Acton's book contains the latest information. We can recommend it.

W. H. R.—1st. There is much difference of opinion as to the propriety of having recourse to the customary stimulants in the treatment of delirium tremens; the majority of physicians are in favour of them. Nevertheless, numerous cases get well without alcoholic stimulants; and in the reports we have seen, the distinction does not seem to be borne in mind that some cases of delirium tremens occur immediately upon a course of hard drinking; other cases occur from the absence of the habitual stimulant. In the first form, the alcohol should be prohibited, and, at first, a *smart purge* given; then absolute quiet observed: in the second form, alcohol is frequently necessary.—2nd. No.

A SUBSCRIBER (Cardiff).—It shall be attended to.

MEDICUS X.—No Medical Practitioner is justified in calling upon the patient of another practitioner, after having been by him introduced to the patient as a professional aid, unless in company with the regular attendant; and no Medical Practitioner of proper feeling would do so. A. was certainly wrong.

M.R.C.S. ENG., and L.A.C.—Either of the Medical agents will inform you.

Dr TUCKER'S note, with second edition of his *brochure*, received.

Mr GEO. CALDWELL.—You should apply to the Registrar-General; or the Return may be obtained, upon payment, from the Parliamentary Publishers in Great Turnstile, Lincoln's-inn fields.

Dr GASON'S last communication has been received, and shall be inserted.

Dr FREKE.—Received.

Mr J. Q. RUMBALL.—Note received, and shall be attended to.

To Gentlemen.—Mr Miles,

(Alfred Webb Miles,) Established 18th February, 1841,

Originator of the WORLD-FAMED TROUSERS, at 10s. per pair, has the pleasure to inform thirty thousand customers that his stock for the forthcoming Winter is now replete with all the new and best designs for Over-Coats, Morning and Travelling Suits, Vests, Trousers, at prices as heretofore. Gentlemen who have not already favoured this establishment with their interest and support are most respectfully informed that it is distinguished not only by the extent, variety, and quality of its patterns and materials, but it excels in the cut and workmanship.

CAUTION.—Mr Miles is not connected with any person imitating and advertising in the same name; his only address is 73 Brook street, Hanover square, and he has no other establishment in London or elsewhere.

Kent's Pharmaceutical

PREPARATIONS OF BRITISH MEDICINAL HERBS.—These Preparations have received universal approbation, and gained first Prizes at the London Great Exhibition in 1851, the Paris Exhibition of 1855, and also the New York Exhibition. They may be obtained of Mr W. Kent, Walsham-le-Willows, Suffolk; or of his Wholesale Agents, Mr W. H. Bucklee, Chemist, 86 New Bond street; or Mr C. F. Buckle, 3 North place, Gray's-inn lane, London.

University of St Andrew's.

—Notice is hereby given, that the next EXAMINATION for the DEGREE of DOCTOR of MEDICINE will commence on THURSDAY, the 27th of DECEMBER.

Fellows and Members of the Royal Colleges of Surgeons of England, Edinburgh, and Dublin; of the Faculty of Physicians and Surgeons of Glasgow, and Licentiates of the London Apothecaries' Company, are eligible for Examination.

Every Canditate is required to communicate by letter with Dr DAY, the Professor of Medicine, fourteen days before the period of Examination, and to present himself to the Secretary for Registration on or before Wednesday, the 26th of December.

(By Order of the Senatus Academicus)
JAMES McBEAN, M.A., Secretary.

St Andrew's, 16th Oct. 1860.

Nervous and Mental

DISORDERS.—Shillingthorpe Hall, near Stamford. —Dr GARDINER HILL, formerly of Lincoln, and late of Wyke house, Isleworth, has fitted up the above [illegible], with its extensive and park-like pleasure-grounds, for the reception of Ladies and Gentlemen mentally afflicted, who will reside with his family, and be under his immediate superintendence.—For Terms, apply as above.

Leeches.—J. Teasdale and Son,

the ORIGINAL PONDERS of LEECHES.—Established 1815.—BEST HAMBRO' SPECKLED LARGE, 15s.; LARGE MIDDLE, 13s.; BEST GREEN (Hungarian), 7s. and 8s.; all of the very best quality, free from mixture with French and other inferior sorts. Importers of Leeches, Manufacturers of every variety of Court and Isinglass Plaister, Medical Plaisters of all kinds, on every description of Fabric.—WILLIAM STREET (continuation of Thames street), and 5 and 6 WATER STREET, Blackfriars, E.C.

Goods free to all parts of London and all trains daily.

A NEWLY-INVENTED APPLICATION
OF
CORALITE GUM-COLOURED INDIA-RUBBER,
AS A BASE FOR ARTIFICIAL TEETH, GUMS, AND PALATES.

BY HER ROYAL LETTERS MAJESTY'S PATENT.

1860, Just Published, Post Free Three Stamps,

Gabriel on the Loss and

ONLY EFFECTUAL MEANS OF RESTORING THE TEETH explains their patented system of supplying artificial masticators, which are warranted to prove successful when all other methods fail, without springs, wires, or metal, and without any operations; and also shows how the best materials with first-class workmanship may be obtained at less than half the usual charge.

MESSRS. GABRIEL,
DENTISTS TO THE PRINCE D'OTTAJANA,
ESTABLISHED 1815 (SEE DIPLOMA),

Surgeon-Dentists (Established 1815),
110 REGENT STREET, next Mechi's; 33 and 34 LUDGATE HILL, City.

TWO CASES OF PURPURA HÆMORRHAGICA.

By JOHN GASON, M.D., &c.,
Member of the Society of Quirites at Rome.

The following account of two cases of Purpura Hæmorrhagica—one complicated with confluent small-pox (called by some authors "black small-pox"), the other with pulmonary apoplexy—have lately come under my care, and will be read with interest.

Miss O., for more than twenty years residing at Pisa, æt. thirty-six years, of a nervo-lymphatic temperament, had for several years previous to this attack a tendency to prolapsus uteri, accompanied by leucorrhœa and large monthly evacuations. The heat of the summer months had considerably debilitated her nervous system, and for the two last years of her life she had great mental anxiety. About a week previous to her illness, July 1st, 1858, she passed through Pisa Hospital, where there was a case of small-pox, on her way to see a patient in whom she was interested. The following history of her case previous to my seeing her was given by the English and Italian medical attendants:—For the two first days she was supposed to have gastric fever, accompanied by her usual monthly sickness; her breathing was very quick, and the fever ran very high. It was supposed that the pericardium was affected, together with "a complication of diseases," and it was decided on to take blood from the arm. There was no change on the third day. On the fourth, an eruption appeared over the body: it presented the appearance of gnat-bites, which, however, gradually increased in size, and of a dark purple appearance. The report of the case further says, that "after this day no change took place, save a gradual increase in the size of the pustules and evident exhaustion of the whole frame." I was sent for and saw her for the first time on the 8th, being the fourth of the eruption. I found her in the following state:—The face, head, and arms were thickly loaded with pustules of a black colour. For the last two days she had discharges of blood from the vagina, anus, and bladder, which coagulated immediately on being passed: that from the bladder came mixed with the urine. She was quite sensible, and aware of her state. Pulse 130, full and bounding; abdominal respiration. On consultation, it was resolved on to give 15 minims of spts. terebinth. every fifteen minutes, acid drinks, wine, cold broth, &c. At midnight she asked for a drink of broth, turned on her side, shortly afterwards became comatose, and died in an hour. No post-mortem examination took place.

The second case is that of a young lady who had an attack of fever, followed by pulmonary apoplexy and purpura hæmorrhagica.

Miss A., æt. eighteen years, of a sanguineo-lymphatic temperament. Some years since had an affection of the spine, which appears to have been of a nervous character, and subsequently an attack of chorea. Her menstrual periods were regular, but the amount of discharge each time small and of short continuance. A few days previous to her being taken ill at Rome, she came from Naples, where a fever of a malignant character had prevailed for some time. I saw her professionally for the first time March 16, 1860. She had then been complaining for some days of lassitude, slight headache, accompanied by shivering, pains in the limbs and constipation of the bowels, but not so ill as to be confined to the house. For the first eleven days there was no urgent symptom, except pain in the head and giddiness in the head when she rose from the bed: the pain was completely removed by the application of six leeches behind the ears. Her pulse, which had been 130 and full, gradually fell to 92. The skin, however, continued hot and dry, and never showed any signs of perspiration. On my expressing a desire for her to encourage perspiration, she replied, "It is quite useless for you to expect it: I never perspired but once, and that but slightly under the arms after violent exercise. When I ascended Mount Vesuvius," she continued, "all were bathed in perspiration but myself: I felt very hot, but did not perspire." The treatment which I adopted up to this time consisted in aperients, refrigerants, and sudorifics, viz., liq. acet. ammon., with potass. chlor., &c. On the eleventh day of her illness she was seized with pain in the lower part of the right lung, increased by making a deep inspiration or by turning in the bed. On examining the chest, I found considerable dulness on percussion along the anterior, lateral, and posterior inferior third of the lung; slight crepitus on deep respiration; occasional cough, but *unattended* by expectoration; foul tongue; hot, dry skin, and flushing of the face; pulse 106. Ordered ten leeches to the side, and the bleeding to be encouraged by fomentation. In the evening she expressed herself much relieved of pain, but continued faint for some hours from the loss of blood, which did not exceed six ounces. The blood extracted by the leeches was florid, and formed a coagulum, from which no serum separated.

29th.—Has passed a restless night; complains of more pain in the side. Her nose bled considerably during the night. Has expectorated, without difficulty and without cough, a small quantity of mucus tinged with dark blood. Skin hot and dry; bowels well opened; pulse 110; urine scanty, but not high-coloured. Ordered blister to the side.

30th.—Has passed a good night; slept well. Epistaxis continues, but not very severely. Dulness on percussion over the inferior portion of the right lung. Respiration more distinct anteriorly. Crepitant rales over a larger portion of the lung. Œgophany distinctly audible in the inferior portion of the side. Pain on pressure between the ribs.

Evening.—Epistaxis from anterior and posterior nares; urine contains blood; skin hot and dry. Ordered plumbi subacetat., ergotine, and ext. rhatani et opii, in pills—acid drinks, and spts. terebinth. ℥ xx., every hour. Mustard poultices to be applied to the calves of the legs, and cold application to the head and neck. I plugged the nose this evening.

31st.—Passed a good night. Says that she feels the side much better, and complains of but slight pain on making a deep inspiration. Skin hot, dry, and rough over the chest; noise in the ears at times; is very pale. Blood oozes through the plug in the anterior nares, but it has ceased flowing from the posterior; it leaves a brown stain on the towel. The surface of the blister is quite black from the effusion of blood beneath the cuticle. There is one small black ecchymosis on the lower lip. Continue the same treatment.

Evening.—Called Dr Deakin into consultation, who recommended a dose of calomel with opium, to be followed in two hours by a dose of castor-oil. As soon as the bowels had been acted on, to have large and repeated doses of tinct. ferri chlor., and turpentine fomentations across the loins.

April 1st.—Has passed a tolerable night; wanders when first waking. Bowels acted three times after the medicine; the motions contained a large quantity of very fluid dark blood. The discharges from the bowels and bladder resemble water in which coffee-grounds have been mixed; there was no offensive effluvia from them. Vomited once during the night, throwing up some blood mixed with the contents of the stomach. The abdomen is less distended than yesterday. She lies without pain or difficulty on the right side; changes occasionally to the left, but prefers lying on her back. The legs are œdematous. Takes a great deal of nourishment.

Evening.—Is weaker this evening. During the day, spots of purpura appeared on the neck, breast, and arms; blood of a brownish colour still oozes through the plug in the anterior nares; roof of the mouth, fauces, and tongue covered with spots of purpura.

2nd.—Raved a good deal during the night; evidently sinking; her senses quite collected up to her death, at four a.m. of 3rd.

Post-mortem Appearances thirty hours after death, in which I was assisted by Dr Deakin.—On the neck, breast, arms, and lower extremities were spots of purpura about the size and shape of a split pea. Over the region of the left kidney were three vesicles, of the size of walnuts, containing a clear pinkish fluid. The surface of the blister over the posterior surface of the right lung was quite black from the effusion of blood beneath the cuticle. A great thickness of adipose tissue lay beneath the skin which covered the chest and abdomen. The muscles were small and wasted. On opening into the anterior mediastinum, about one ounce of clear fluid flowed out. The cavity of the right pleura contained upwards of three pints of a thickish black fluid, apparently blood, and similar to what was passed from the bowels and kidneys; that from the latter, however, evidently containing urine. The inner surface of the pleura was mottled with petechiæ of a very dark colour. The upper and middle lobes of the right lung were quite healthy, of a greyish colour and very pale, emphysematous to the touch; did not contain any tubercles, and when cut into were quite bloodless. The posterior portion of the inferior lobe was of a liver-like substance; its appearance, when cut into, was as if ink had been strained through it, leaving all the sediment behind. No blood oozed from it, or could be forced from it when pressed with the scapel; and its cut surface resembled that of the liver. The cavity of the left pleura contained about six ounces of the same dark liquid as that on the right side. The lung itself was pale, but healthy; and the pleura was also mottled, but to a much less extent than that on the right side. The pericardium contained about two ounces of clear liquid. The heart was small, pale and flaccid, and had a good deal of fat deposited between its muscular substance and the pericardium, at the point of union of the auricles and ventricles, and along the trunks of the coronary arteries. The stomach and small intestines were distended with gas. The internal surface of the stomach was mottled over with purple spots. About four inches of the lower part of the small intestine was of a pinkish colour, evidently caused by congestion. The liver was much paler than natural, but otherwise healthy. The gall-bladder was of a light yellow colour, and contained a small quantity of yellow bile. The spleen was of a dark slate colour, but healthy. No liquid of any sort was contained in the abdomen. The right kidney small; its cortical substance of a light brown colour, resembling that of the liver; the tubular substance injected, and of a bright red colour. The infundibula contained some dark grumous blood. The left kidney was nearly double the size of the right; its cortical and tubular substances were of the same colour throughout, of a much deeper brown than the right, and appeared very much congested. The urine passed two days previous to her death gave the following signs:—It was of a very dark colour, and contained a brownish sediment when allowed to stand for a short time. On filtering it and subjecting a portion to heat, a quantity of separate red globules were deposited, and an albuminous substance (which was not affected by the addition of nitric acid) appeared floating through the fluid. On the addition of a solution of hydrarg. bichlorid. to another portion of the urine, a copious deposit was thrown down, which was in like manner unaffected by the addition of nitric acid. The specific gravity of the urine was 1·002.

Miss A., during health, had a great dislike to vegetables, of which she ate but very sparingly. However, she was fond of oranges, of which she partook every day.

(To be continued.)

CLINICAL REMARKS ON THE MEANS OF FACILITATING THE EXPULSION OF THE PLACENTA,

SO OFTEN DIFFICULT IN CASES OF ABORTION IN THE THIRD OR FOURTH MONTH.

By M. A. LIZÉ,
Of the Hospice de la Maternité du Mans.

When miscarriages occur about the third or fourth month, parturition may be attended with serious difficulties. These are dependent on the firm union which the placenta—already voluminous—has with the internal surface of the uterus, which cannot contract with energy sufficient to overcome the manifold utero-placental adhesions. When repeated uterine contractions have ruptured the amniotic bag, which forms near the os, the waters escape, and the embryo is expelled, and there escapes no inconsiderable quantity of blood in a liquid or coagulated state. The uterus, disencumbered in great part of its contents, becomes contracted, and, if there is no intervention on the part of the accoucheur, the os,

contracting at the same time, may incarcerate in the uterine cavity both the placenta and the membranes. The introduction of the finger in such cases becomes impracticable; and in spite of the authority of Professor Velpeau, who directs the use of ergot of rye with the view of overcoming the obstacle, I believe, with Cazeau and Pajot, that success does not often follow the administration of that substance. A wiser course is to wait, and watch the symptoms that may arise from retention of the placenta. Nevertheless, should active intervention be deemed necessary, the use of uterine douches, lately recommended by M. Pajot, may be effectual in removing portions of putrid placental *débris*, and producing so much dilatation as to allow the introduction of the mole-forceps. If hæmorrhage occurs, plugging, and the use of refrigerants, would be sufficient.

But the state of things is not always so bad; and when the practitioner arrives some time after the expulsion of the fœtus, he often finds the uterine orifice partially open, and embracing some portion of the placenta. In such cases it is sufficient to seize the presenting portion with the index and middle fingers, in order to remove the placental mass; and in cases where the index and middle fingers do not suffice, the mole-forceps of Levret, or Duges's hook, will be successful. When the numerous adhesions of the after-birth cannot be overcome by these means, and there is threatening hæmorrhage, there are distinguished accoucheurs, Cazeau and Chailly for instance, who recommend plugging, and the use of ergot of rye. Without wishing absolutely to proscribe this medicament, as M. Pajot has done, I yet fear that it might induce spasmodic retraction of the internal orifice, and I do not think of using it till I have introduced a finger into that aperture. In this way the index finger, if kept *in situ*, opposes the retraction of the uterine orifice, and serves as a plug till increasing uterine efforts finish the expulsion of the after-birth. These considerations are applicable to the cases where the practitioner has not been present from the first, or witnessed the progress of the absorption, but has yet been able to ascertain that the fœtus only has been expelled, and that the secundines remain in the uterine cavity. But when the practitioner arrives immediately after the expulsion of the fœtus, he ought, says Bandelocque, to introduce one or two fingers into the uterine orifice, to prevent further contraction and to favour dilatation; for when this is effected, expulsion follows in a very short time without any other precaution. Recent obstetrical treatises declare plainly enough the rule to be followed when professional aid arrives some time after the expulsion of the embryo, but they are silent as to the *modus, operandi* to be followed by him who has been present during the various stages of the abortion. The recommendation of Baudelocque, however, should be immediately put in execution, if it be wished to avoid that firm contraction of the neck of the uterus which leads to retention of the placenta, and to its unpleasant consequences. I must nevertheless add, that introducing the index finger as directed does not always suffice for the easy and expeditious extraction of the placenta. In order to hasten the detachment of the placental nerves, it is advisable to associate the use of ergot with the means recommended by Bandelocque.

Let us now see whether obstetric practice lends its sanction to these precepts.

Case 1st.—Madame D——, a primapara, twenty-six years of age, of a highly sanguine temperament, was seized at four in the afternoon with copious discharge of blood, towards the end of the third month of pregnancy, exactly at the menstrual period. From the arm were taken 125 grammes of blood, and three small opiate enemata were administered, allowing half-an-hour between each; when the sanguineous discharge ceased. Twenty-eight days later, Sept. 8, venesection repeated to the same amount, and absolute repose enjoined: but, notwithstanding these necessary precautions, a very copious hæmorrhage took place on the 11th, at eight o'clock a. m., and acute pains, beginning at the umbilicus, announced the commencement of labour, which was met by appropriate treatment. On the 12th, at five o'clock p. m., the fœtus and numerous clots of blood were expelled: but there was retention of the placenta in the uterine cavity. My first visit was ten minutes after the expulsion of the fœtus, when blood continued to flow in abundance. The os was partially open, and contained a considerable portion of the placenta, which I now endeavoured to remove, but tore. I again introduced the index finger, keeping it *in situ*, and two grammes of ergot of rye were given in divided doses. The uterine efforts, aided by friction over the hypogastrium, at the end of twenty-one minutes effected the expulsion of the placenta, together with a quantity of coagula; after which there was prompt receding of the uterus, and complete cessation of hæmorrhage.

Case 2nd.—November 26th, towards ten o'clock p. m., Madame B——, a primapara, thirty-one years of age, of a nervous temperament, miscarried at the end of the third month. At my first visit, the following morning at nine, I readily ascertained the presence of an embryo embedded among the clots of blood which I examined. A manual examination revealed the following:—A cavity formed at the expense of the cervix uteri; the external orifice much dilated; the internal orifice spasmodically contracted, so as not to admit the tip of the index finger. A portion of the placenta was embraced by the latter. There is no hæmorrhage *per vaginam*, but meteorism and pain of the hypogastrium. Mercurial frictions over the abdomen, and injections *per vaginam* with infusion of the leaves of belladonna. At eight o'clock p. m., the same day, violent shivering, accompanied with extreme restlessness; skin hot and dry; pulse 115; frequent vomiting; great sensibility of the abdomen, which is now tympanitic. To this part twenty-five leeches were applied, and twenty centigrammes of calomel were directed to be given in ten doses. Next day, the 28th, at ten in the morning, a consultation with Dr Leconteux. The abdomen is less distended, and less painful on pressure; abundant evacuations, and pulse 104. Efforts to overcome, with the index finger, the resistance presented by the internal orifice, resulted in detaching the portion of placenta still remaining in the cavity of the cervix. Prolonged hip-bath; vaginal injections with decoction of cinchona-bark, and a potion containing two grammes of the dry extract of the same substance was next directed. The same day, at three p.m., vomiting, with sharp pains in the abdomen. The antiseptic potion discontinued; four pills, each containing one centigramme of thebaic extract and half a centigramme extract of belladonna. Mercurial frictions to the abdomen, and frictions with belladonna.—29th. The peritonitis almost gone; a reddish fluid, mixed with putrid *débris*, begins to flow from the vagina. There is still the same resistance of the internal orifice of the cervix. Prolonged hip-baths, and uterine douches in place of vaginal injections.—30th. *Evening.* The abdomen soft, and the tumefaction gone; no fever; slight oppression, of a spasmodic nature; the internal orifice, now relaxed, allows the introduction of the index finger and a large elastic sound, by means of which tepid water is gently thrown into the cavity of the uterus, expelling a quantity of putrid matters. Use of cinchona renewed, with beef-tea. During the next and some subsequent days, the vaginal discharge and the injections continue to bring away portions of the placenta; and the state of the patient becomes more and more satisfactory; and by the 5th of December she had quite recovered.

There is one thing that strikes us in this case—the rapid putrefaction of the retained portion of the placenta. In eleven hours the effects of putrid absorption were seen in the peritonitis that followed, which yielded to antiphlogistic treatment; and it will be observed that the general state of the patient improved in proportion as the uterus became disencumbered of its putrid contents. There would have been imprudence in trying to introduce the finger or mole-forceps through the os in order to remove the remaining portion of placenta; and if, after the subsidence of the abdominal inflammation, ergot had been given with a view to accomplish the same end, the symptoms, far from being ameliorated, would only have been much aggravated. The vaginal injections and uterine douches alone contributed to relax the cervix, and to produce so much dilatation of the aperture as to give free passage to the placental *débris*. The absence of hæmorrhage in this case is, no doubt, owing to the uterus having sufficiently contracted after the detachment of the after-birth.

(See an article on this subject in Our Note Book.)

ON

PERVERSION OF THE MORAL AND AFFECTIVE FACULTIES

IN THE PRECURSORY STAGE OF GENERAL PALSY.

By M. BRIERRE DE BOISMONT.

(Read before the Academy of Sciences.)

Thirteen years ago, I published in the 'Gazette Médicale' the following notes, accompanied with two cases in illustration:—"Of the authors who have written with real ability on general palsy, no one has spoken of the precursory stage of this singular disease, which, in a moral and medico-legal point of view, is a subject of the greatest interest. This stage, which in some cases can be traced as far back as six, seven, or more years before insanity bursts out, is characterised by *perversion of the moral and affective faculties*, without rendering the subjects of these changes less fitted to discharge the duties of social life, or their employments. Their families, surprised and distressed, murmur at the commission of acts of indelicacy, fraud, and debauchery, for which they were not prepared by any antecedents. Injuries are extenuated, damages paid, complaints silenced, till this secret and long-continued martyrdom is put a stop to by the appearance of general palsy."

The following is a case of this kind:—I was called in consultation in the case of a ministerial officer, whose purloinings at a sale made much noise some years before. A charge had even been made, and an order issued for his arrest. As his act was inexplicable, the complaint was withdrawn; but he had to resign his charge.

The cases I had already collected having reference to this subject, led me then to believe that this person was under the influence of this precursory stage of general palsy; and the interview greatly excited my curiosity. I was all but convinced that I was going to see an insane paralytic. On entering his cabinet, and before any information was given me, the first words this person uttered revealed to me the nature and lengthened existence of his malady. His utterance was embarrassed, there was manifest incoherence, his physiognomy as if petrified, and his gait heavy and tottering. Eight years had elapsed since his purloinings had been discovered, but only a few months since his mental malady had become apparent.

This case, and others, had arrested my attention; and in a hundred which I have myself recorded, and communicated the results to the

Medico-Psychological Society, I have noted all the changes of humour and character that could throw light on this subject. The change most frequently observed, and that may be seen in three-fourths of the cases, is a greater or less degree of irritability—bursts of impatience, anger, or violence. In a more restricted number of individuals, the disease, on the contrary, is preceded by a state of placidness, indolence, and apathy. Such persons reason well; admit that they should be occupied, should act and take their part; but between their admissions and the actions that should follow, there is always an impassable abyss which they cannot clear. In place of angry irritability and reasoning apathy, or of one of these without the other, we observe perversion of the moral or of the affective faculties. Persons who had hitherto shown themselves to be religious, pure in their moral conduct, upright, &c., exhibit contrasts the most opposite. It is the more important to be acquainted with this symptom, that it happens often that the faculties seem intact, and that the relatives and friends have no suspicion of the actual disturbance. Of these perversions the most striking is a mania for stealing, which may be referred to a disposition of mind very common in those who suffer from general paralysis, leading them to believe themselves rich, powerful, and masters of all they see. This mania for grandeur and riches, this exaggeration of self, some would greatly restrict; but in one hundred cases, we have ascertained its existence in sixty-four: and at the last sitting of the Academy, M. Baillarger said that it is one of the principal signs of the disease. These notions of riches and power, by which these patients are led to commit larceny, in the belief that everything is their own, often involve them in the most troublesome consequences. People of business, having suspicion of their unsound state, and the mental weakness which is its result, entangle them in disastrous undertakings; and it was but a few years ago that one of my patients had to defray a balance of a hundred thousand francs. At the termination of the sitting in which I read this paper, one of my friends, whom you all know, said to me, "Had these cases been made public, my son-in-law would not have lost eight hundred thousand francs, ruined his wife, and left five children to my care."

The early approaches of general palsy develop not only the inclination to purloin, but may also lead to shameless abandonment. A bankrupt merchant was placed in my establishment, who was supposed to simulate madness. His friend told me that several months before his admission, he began to go from home without ostensible object, and in a mysterious manner; and that after being some time watched, it was clearly ascertained that he frequented houses of bad fame—a practice altogether opposed to his principles and previous conduct. During eighteen months that he was under my observation, and was examined at various times in order to obtain exact information of his intellectual state, he ensconced himself in a kind of mutism that seemed strange, and that stayed legal proceedings. When pressed with questions, he contented himself with saying, "I have done what people in business do: all will be explained and justified." One morning, at our visit, he came to me with smiling looks, and asked me, with much stammering, *to lend him four millions.* From this time general palsy made rapid progress, and in two months this patient sank into the last stage of dementia.

It is, then, certain that general palsy may produce striking changes in the character and conduct of individuals, and give rise to eccentric, reprehensible, and evil actions. No doubt such facts are seen in ordinary life, and are accounted for by the seduction of passion; and then they come within the province of the magistrate. But more frequently it happens that these sudden and unlooked-for falls are the result of mental disease, and especially of general palsy. Now, in cases of this kind, there are frequently precursory symptoms, or *fore-runners*, as they are well designated by Forbes Winslow—a celebrated English mad-doctor—in his remarkable book on 'Obscure Diseases of the Brain and Disorders of the Mind.' These are the early symptoms that must be sought out and brought in evidence. The index that should first guide the physician is the idea of disease. In most cases, in fact, where these transformations of humour, character, and conduct are remarked, there is reason to fear general paralysis; where the age is between thirty-five and forty-five, where there are sexual excesses with intellectual excesses, and hereditary predisposition combined, the presumption acquires still greater strength.

Independently of the characteristic symptoms now mentioned, we must overlook a circumstance very common,—and that is cerebral congestion. This may consist in simple stupor or vertigo, or may pass unperceived, though usually observed, and has serious consequences. This congestion produces feebleness of the intellectual faculties, absence of mind, and forgetfulness. The mind no longer possesses its accustomed distinctness, precision, and firmness; and if you engage your patient to give you an account of some transaction where explanatory illustrations are required, you remark trenchant differences between this task and those he has been in the habit of executing. His benevolence is more than ordinarily expansive, and he mingles with his discourse a degree of confidence which at a later period becomes ambitious mania. At other times, but more rarely, we observe a state of sadness, with tendency to melancholy or hypochondriasis.

But disorders of the muscular system are the criterion of the disease. Of these there is one that may be considered as very important, and shows itself by passing tremor of the lips, a scarcely sensible degree of embarrassment in the speech, hesitation in pronouncing some letter or word, and not recurring but at long intervals. This symptom, taken alone, cannot suffice, though it is one of great value; but when it is joined to diffused diminution of motility—which you can ascertain by desiring your patient to stand on one leg, or to press firmly your hand—the certainty of general palsy grows stronger. To these symptoms must be added inequality of the pupils, powerlessness or exaltation of the sexual functions, diminution of cutaneous sensibility, certain tremblings of the muscular fibres, the results of analyses of the urine, and the application of electricity.

On reviewing the cases in this work, and the observations to which they conduct, we think we can of right conclude:

1st. That individuals who, at a period of life already advanced, manifest a change of character and conduct, and commit acts that are quite at variance with their principles and antecedents, give reason to suspect an alteration of their intellectual faculties.

2nd. That this probability becomes certainty when we find also the existence of the characteristic symptoms which we have enumerated.

3rd. The uncertainty that may still in some measure attend the disease disappears with continued observation, because in ninety-five out of every hundred cases the tendency of general palsy is to increase, and terminates fatally in the same proportion.

4th, and lastly. The symptoms described have a real importance, for they put us on the track of general palsy when it has not yet declared itself.

THE SPIRIT OF THE PERIODICALS.

The 'Lancet' commences with a continuation of Mr Hilton's Lectures on *Pain*. This article is followed by a paper by Dr W. Hughes Willshire, on a *Case of Diabetes*. The article is interesting; we therefore quote it:

"Gentlemen,—There is a female patient, named P. E——, in the Clinical Ward, to whom I am desirous of directing your attention. I have already incidentally referred to her, but as her case is one of much interest, and as she has now been some time in the hospital, and we may possibly soon lose her, I wish to enter into some details about her whilst she yet remains with us.

"The patient is twenty-nine years of age, married, and has one child. She was admitted into the hospital as far back as the 12th of May. She then told us—or at least my clinical clerk, Mr Belcher, who took the case down—that a few months after having had ague, in 1857, she began to be troubled by intense thirst, and by being very frequently obliged to micturate. The amount of both thirst and urine had been increasing ever since. In March, 1858, she first noticed her eyesight to become affected; there was a dazzling, afterwards a kind of mist or smoke seemed to pervade everything, and the power of vision gradually went away, leaving her blind in both eyes. The catamenia had stopped eight months back, and had not reappeared. Latterly her skin had become dry, and inclined to scale off in the winter. During the previous summer, however, she sometimes perspired freely. Her appetite for the last six months had become ravenous. She had suffered from thirst ever since she had ague in 1857, but of late her desire for drink had much increased. She has long been obliged to rise several times during the night to pass urine. The bowels are usually very costive, being occasionally confined for a week together; but sometimes she is liable to a slight attack of diarrhœa. She is very emaciated, but has a rather florid colour, and seems happy and resigned in mind. She has not any cough, and does not look phthisical. She entered the hospital to have her eyesight remedied by Mr Hancock.

"Soon after her admission, my colleague kindly referred the medical department of her troubles to my clinical service. It was not a difficult matter to arrive at the nature of the sufferings of thankful and happy-minded P. E——. You have heard that she was very hungry, very thirsty, and very thin; that her skin was dry and scurfy; her bowels confined, and that she passed a very considerable quantity of urine. We found her so weak that she was forced to lie in bed, yet hinting that she could *eat* a little more if more was offered her. We smelt her breath, and noticed that it had a very marked sweet-apple or chloroform-like odour, though not such a strong one as had another diabetic patient of mine upstairs, the approach to whose bed was something like going near an unstoppered bottle of chloroform. There is no exaggeration in this statement; some of the last session's students will bear me out in what I say, as they were witnesses to the fact.

"Now these were general and vital signs, all pointing to the presence of sugar in the patient's urine. Well, then, we examined her urine. We found it voided in quantity between eleven and twelve pints in the day. It was of a very pale straw colour, sweetishly faint in odour, clear, and having a specific gravity of fully 1040. Upon applying the tests of Trommer, Moore, and using the solution of Barreswill, we found the presence of sugar abundantly demonstrated. Some of you will recollect that we afterwards put some yeast to the urine, and so availed ourselves of the fermentation test. This test we also had recourse to again only the other day. It was clear, then, that this woman had glucosuria, and was passing a considerable amount of solid matter in the urine during the twenty-four hours. We examined her lungs, but could not detect that she had that common accompaniment of diabetes—viz., phthisis. But if she was not consumptive, she was *blind*. Mind, this is a point of great interest in this case. She was blind, I say; she had *cataract*, and cataract of both eyes. Before, however, I touch further upon this matter, let me tell you what we did for the diabetes. I ordered her a grain of quinine and a grain of opium three times in the day, an occasional warm bath, and purgatives when necessary. All vegetable matters, except coarse brown bread with the bran in it, and which is made, I may remark, purposely for us by one of our governors, (Mr Robb, in St Martin's lane,) were prohibited. A rigorous embargo was laid against sugar, but *four* meat diets, with extra milk and eggs, were allowed her to make up for these denials. Soon after this plan of treatment was put into force, the patient began to improve; she got much stronger, the quantity of urine lessened, and the gravity of it became often much lower. She ceased to rise to micturate in the night, the bowels became more manageable, and the thirst much less intense. Sufficient for me to say, she now passes (Oct. 15th, 1860) four pints and a half of urine during the day, the specific gravity of it being from 1038 to 1040. This quantity, with an occasional lower degree of gravity, has been the rule for some months past. Once the quantity went down to three pints, and had a gravity of 1026, but sugar was still contained in it. Then both quantity and gravity rose again, and do what I may, I cannot get it less than four pints, with a gravity of 1038, for any length of time. The only addition to her treatment up to quite recently has been, that the opium and the quinine were each increased to

two grains three times in the day. Once for a few days the patient felt so well, that she could not refrain from eating some potatoes. The urine rose in quantity and gravity, and she had a slight attack of diarrhœa. But she has undoubtedly gained flesh since she has been under the treatment I have mentioned.

"Now to revert to her blindness. You hear the patient had cataract of both eyes, for the relief of which she had sought Mr Hancock's skilful assistance. Let me now inform you that an American physiologist, Dr S. Weir Mitchell, published in January of the present year a memoir showing that cataract could be produced in frogs by introducing sugar into their system; and his further experiments proved that a peculiar form of cataract was a pretty constant attendant upon 'sugar-poisoning.' This paper coming across the notice of a gentleman whose genius for physiology is only equalled by his acuteness and persevering energy—namely, Dr B. W. Richardson,—served at once as a hint to him for undertaking what he has called the 'synthesis of cataract.' From March last up to the present time, I believe, he has been more or less occupied in its investigation. He first began by introducing syrup-of-cane sugar into the living system of fishes and frogs, and, as a rule, it may be said that 'sugar-poisoning' and opacity of the lenses were produced. Dr Richardson then experimented with grape-sugar and with syrup-of-milk sugar, and the like results followed. He then passed on to mannite, and the effects were the same; but in his next experiments with liquorice there was a want of agreement. A grand point now with Dr Richardson was to be enabled to introduce true diabetic sugar into the living organism. I am glad to think that my colleague, Mr Hancock, and myself were enabled to place our patient, Phœbe E——, at Dr Richardson's disposal for this purpose. We had the pleasure, some of you will recollect, of seeing Dr Richardson at this hospital during the early part of the summer. He obtained from us several pints of the patient's urine, with which, to use his own expression, he 'made numerous interesting experiments;' some of these, I may add, were performed at Bedford on June 15th, before the members of the South Midland Branch of the British Medical Association. As a rule, again, symptoms of 'sugar-poisoning' were produced, and the cataractous condition was 'markedly brought out.' Other series of experiments have also been continued by him, but for further information about this gentleman's inquiries I must refer you to his papers now publishing in Dr Brown-Séquard's 'Journal de la Physiologie.'

"Attention was now directed to the chronicles of *pathology*, to discover if they gave any support to this physiologic view of a causal connection between diabetes and cataract. The most concise *résumé* of what is to be obtained in this field you will find in the last volume of Guy's Hospital Reports (Third Series, vol. vi., p. 266), in a paper by Mr J. F. France. He there tells us that he himself drew attention to 'diabetic cataract' in January, 1859, in the Ophthalmic Hospital Reports, but that Dr Mackenzie of Glasgow had alluded to it in 1854. More recently Messrs Duncan, Wilde, Walton, Veasey, Sloane, Newman, and Barton have instanced cases bearing upon the point. These you will find specifically alluded to in Mr France's paper. I have referred to Schauenburg's 'Ophthalmiatrik' (p. 114); there I find it stated that diabetes is very often followed by soft cataract, and Unger's name is brought forward in support of the assertion. In 'The Lancet' of April 28th, 1860 (p. 424), there is a note to the effect that Graefe had stated, in the 'Deutsche Klinik,' that diabetes was very frequently the cause of cataract. It is right to mention, also, that Dr Richardson admits both Dr Mitchell and himself have been forestalled by Kunde, who some years ago travelled far in the same direction—the synthesis of cataract ('Journal de la Physiologie,' p. 450). With regard to 'diabetic cataract,' Mr France generalizes thus: the cataractous condition is symmetrically developed upon both sides; the lenses increase very largely in their antero-posterior diameter; the cataracts are of soft consistence; the ocular affection comes on only after the diabetic state has existed for some time, and there has not in any case been reason to suspect further disease of the eyeball. (*Op. cit.*)

"With regard to our patient, I may remark that Mr Hancock first operated upon her on June 9th; and he informs me that the cataracts were double and of soft consistency, and that he did not observe that the lenses were larger in any direction than usual. He likewise says that absorption did not by any means proceed so rapidly after the operation as it usually does. The operation performed was that called 'breaking up.' Mr Hancock again 'broke up' the lenses upon October 8th, and he tells us that although the lens in either eye is not as yet absorbed, the patient is beginning to see very satisfactorily, particularly with the left eye; so that the result of the operations may be considered favourable. Soon after the last operation was performed, some inflammation of the left eye occurred, followed by a slight adhesion of the iris. Mr Hancock and myself had some talk together about suspending the quinine and opium, and giving a little mercury. Although not without some misgivings regarding the possible effects upon the diabetic condition, the last-mentioned drug was had recourse to, and certainly with benefit to the visual organs. I have been very anxious about the urine, therefore, and have several times examined it. To-day we made some inquiries, you will remember, about this excretion in the wards. The specific gravity of the urine we found to be 1040; the quantity rather more than four pints; and the presence of sugar was indicated by the various tests we employed. The patient told me to-day that she felt weak, and was obliged to rise during the night to pass urine. When I inquired if she had an appetite for her four meat diets, she smiled, and said, 'Oh dear, yes!' as if it was a very easy matter for her to dispose of our commissariat allowance. As I intend, with my colleague's permission and assistance, to inquire into the state of the urinary secretion of his cataractous patients at our neighbouring Ophthalmic Hospital, it is probable you may hear something more from me upon this matter."

Dr Chas. J. Hare reports in the same journal a *Case of Secretion of Milk from the Right Axilla.*

"The following rare case of the secretion of milk from the axilla came under my observation amongst the out-patients of University College Hospital.

"Mrs M. S——, aged thirty-seven, was admitted an out-patient for slight dyspepsia at the end of April last. On a subsequent visit, on May 14th, she informed me that she had a small swelling under the right arm, which for some while past had given out a white milky-looking discharge, presenting exactly the same appearance as the milk from the breasts. She was a woman of middle or slightly below the middle stature, of good conformation, somewhat thin, hair dark; her general health had been good. She was confined of her seventh child on February 2nd; had suckled all her children, and at no period of her former lactations, or at any other time, had she observed any swelling in either axilla. On this last occasion she had as good a supply of milk as usual, and had reared this child also at her breast. It was on the night of her confinement that she first observed a swelling in the right axilla, which she described as being (when she first noticed it) 'nearly the size of half a walnut.' It did not increase much in bulk, but became harder, and caused some pain as low down as the elbow. It was not until the end of a month that it discharged a little fluid, which was then, as it had continued to be up to the time of my seeing her, of a decidedly milky appearance. The discharge of the fluid gave relief to the pain. Though the oozing had continued, and had always been of the same character, it had varied somewhat in amount. If she did not exert herself or use the arm much, less was discharged; but as she attended to her domestic duties, enough generally escaped to moisten the linen, and sometimes even more than this. By pressure she had always been able to force out more of the fluid.

"On examining the axilla, I found an irregularly ovoid prominence situated rather nearer the posterior and outer than the anterior and inner part of that region; it was nearly an inch in length, and more than half an inch in breadth, and its longer axis was placed somewhat obliquely with regard to the axillary space. Though the prominence was distinctly visible, yet the mass felt thicker than it appeared to be, as a notable portion of it lay buried in the cellular tissue of the axilla. Its entire bulk was about that of a large filbert or a small half walnut; its outline was but moderately well defined, and not perfectly regular or circumscribed, for the little mass seemed somewhat blended with the loose cellular tissue of the axilla. Its substance was firmish, but by no means so hard and resisting as an enlarged gland usually is in that situation; indeed, by moderate pressure, its shape could be readily altered, though it instantly resumed its original form on the pressure being removed. The skin over the swelling presented no redness, nor any different appearance from that of the rest of the axilla; there was no trace of a nipple, and indeed so extremely minute was the aperture through which the fluid escaped, that it was impossible to say at what point it made its appearance until the surface had been wiped dry, and a fresh portion was forced out by pressure. It was then found that there was but one orifice, which was situated near the outer and posterior end of the mass, and which seemed scarcely, if at all, larger than that of one of the sweat ducts; there was no papilla or elevation of any kind at the opening. On pressure, the milky-looking fluid readily trickled out, as much as the fifth or sixth (at least) of a drachm being collected in a test-tube in the course of a minute or two; but, even of this quantity, the first portion came away more readily than the last few drops. As already stated, the fluid had all the usual appearances of normal human breast-milk, being a thin, bluish-white liquid, rather sticky when rubbed between the fingers. The small quantity collected in the test-tube, being allowed to remain undisturbed, was found after a few hours to form on its surface a layer of cream. A drop of the fluid being, as soon as collected, placed under the microscope, it was seen to be rich in the well-known, variously-sized oil-globules of milk, without any other observable form; nothing resembling a pus-globule was detected."

In the course of some remarks upon the case, Dr Hare observes that the evidence is all in favour of the small mass in the axilla being a portion of mammary substance, and not lymphatic gland.

Dr Joseph Rogers reports a *Case of Idiopathic Tetanus.* We extract it.

"Having been sent for on the evening of the 2nd of this month to the Infirmary of the Strand Union to attend a case of hæmoptysis, my attention was drawn by the nurse to a patient admitted in the course of the afternoon, stated to be suffering from stiff neck and sore-throat. She informed me that shortly before, she was at his request raising him in bed, when he was suddenly seized with a fit of convulsions, and his arm being round her neck, it closed upon her with such force as almost to strangle her. On inspecting him, I found him stretched at length on his bed, bathed in sweat, with a pulse of 120; the fingers were still rigidly closed upon the hand. On inquiry, he informed me that he was about fifty years old; that he had been ill some days under the care of Mr Jones, the out-door medical officer, and that, getting worse, he had been sent into the house. He complained of stiffness about the neck and jaws, and some pain at the epigastric region, the abdominal muscles being unusually hard and resisting; and on my requesting to see his tongue, he said he could not put it out, as he could not open his mouth. I was enabled, however, to see it by the fact of his having lost all his front teeth, and his jaws being kept slightly asunder by the molars of each side. It was large, and covered with a creamy mucus. He said he could swallow but imperfectly. He denied having any wound or other injury about his body, but referred his sufferings to exposure to wet, &c., in his occupation as a street-sweeper in St James's. His bowels had been opened that day, but he had had no sleep the previous night. The fits, as he called them, came on at intervals of two or three hours. The countenance was peculiar. He seemed to be neither laughing nor crying, but a mixture of both, and being nearly deprived of sight, owing to disease of his eyes, his appearance was unprepossessing. Diagnosis, probably tetanus, of idiopathic type. His intellect was perfectly clear, but he was garrulous in the highest degree, his remarks being wholly directed to his sufferings and previous pursuits in life. Ordered powdered opium, five grains; powdered camphor, twelve grains; mucilage, sufficient to make four

pills, one to be taken every two hours ; mustard plaster to be applied to the whole length of the spine for twenty minutes.

"Oct. 3rd.—Nine a.m. : The patient appeared better ; had slept from four to five hours. He had had two convulsive attacks since last night, which evidently, from the description of the nurse, were opisthotonos ; jaws still firmly closed ; pulse 120, small and weak. Ordered, large gruel enema, with oil of turpentine and olive oil ; extract of purified cannabis indica, four grains ; camphor, twelve grains ; mucilage, sufficient to make four pills, one to be taken every fourth hour ; beef-tea, a pint ; wine, five ounces.

"4th.—Nine a.m. : Same as yesterday ; had slept but little ; had had about six attacks, coming on generally after any attempt to raise him in bed. Enema brought with it no fæcal admixture ; a small quantity of high-coloured urine had been passed ; pulse 120. Pills to be repeated, and two drops of croton oil ; enema to be repeated.

"5th.—Half-past nine a.m. : I was requested by the attendant to go into the ward immediately, as he was in a fit. On my arrival, it had nearly passed away. He was lying at his full length in bed, bathed in sweat ; pulse extremely weak and rapid ; breathing hurried ; countenance cadaverous ; slight froth about his mouth. In about four hours after he died.

"Owing to the necessity of obtaining the consent of friends previous to an autopsy, (*vide* Poor-law Regulations on this head,) the examination was delayed until the evening of the 8th, eighty hours after death. Cadaveric rigidity of his limbs still existed. On cutting down upon the spine, the veins were found extremely gorged with fluid blood. On exposing the membranes, the dura mater was evidently congested. On raising this, there was noticed opposite the fourth cervical vertebra, upon the pia mater, or within its meshes, a small quantity of bloody serosity, the pia mater being extremely injected the whole length of the cord as far as the cauda equina. The cord was removed, and on cutting across it, its vascularity was found much increased, especially in its cervical portion. The membranes of the brain were similarly injected, and the brain itself congested. On cutting it across, the puncta vasculosa were more than usually conspicuous. Its base was also congested, especially near the pons ; a small quantity of fluid in the lateral ventricles. The medulla oblongata was pale by comparison with the other parts of the brain and cord. The cerebellum was also much congested. Abundant mucus, thick and tenacious, hung about the mouth and upper part of the larynx. The whole of the lower lobe of the left lung was extremely congested, felt hard and heavy, and was black in colour : portions of the right lung similarly congested. The heart was flabby ; the right side contained imperfectly-coagulated blood. On the left side, at the angle of junction of two of the aortic valves, and extending backwards to the base of the same, was a calcareous deposit, about the size of a large pea ; commencing atheroma of the artery beyond them. The kidneys were diseased, having undergone partial atrophy, but, like the other organs, were extremely congested. Nothing else unusual was discoverable.

"Perhaps some of the readers of the 'Lancet' would be able to throw some light upon the causes in operation that led to the attack of tetanus. For my own part, I have no opinion to offer, save that possibly some relationship existed between the kidney disease and the spinal irritation upon which the tetanic spasm depended."

Mr Furnell reports, in the same journal, a *Case of Chronic Hepatitis* with considerable enlargement yielding to the use of the seton, the reappearance of acute hepatitis, the formation of abscess, early puncture, and recovery.

The 'Medical Times and Gazette' opens with Dr Goodfellow's Lectures on *Bright's Disease*.

Dr Hobson, the Medical Missionary in China, contributes an article on the *History and Present State of Medicine in China*. This article is written in the elaborate essay style, and consists of general remarks upon the characters of various peoples and the writings of Hippocrates. The part relating to the subject described in the title is as follows :

"I wish I could say as much of any Physician in China. The most celebrated is one Hwa-to, who was contemporary, or nearly so, with Galen. It is reported of him that he performed several surgical operations, and effected many wonderful cures, which are handed down as trophies of medical skill, but which none of the present day would presume to undertake. Without knowing much about him, or what he knew, he has been placed prominently forward as the great patron of the healing art in China, and he and a few other celebrated ones have been honoured with the designation of the 'Nation's Arm.' The highest compliment that was considered possible to be given to a European Surgeon after performing some surgical operation was that of his being 'a second Hwa-to!' It is difficult to speak with any certainty when and how the healing art commenced in China. Medical books in the present day are very numerous ; but they are all based on the supposed superior light and experience of the ancients ; and there seems no desire to improve upon them : hence the state of Medicine is now what it has been for many centuries past. It is not encouraged by the Government : there is no Medical College except at Pekin, and it has no examining powers, nor does the law require any one to study there, except those who are designed to take care of the Emperor's sacred person. The dead body is regarded by the Chinese with a superstitious dread, and from this cause, and the respect enforced by Confucius to be shown to deceased friends, there is everywhere in China a deep-rooted aversion to touch a corpse, still more to cut or maim it in any way, even for purposes of medical inquiry. The Doctors unite extremely well on medical jurisprudence, and in case of sudden or suspicious death they are obliged by law to examine with all possible care the probable causes of violent death ; but, while the external examination is most minute, it stops there : the direction, depth, and consequences of a penetrating wound are left unexplored ; such a thing as probing a wound, whether the person is alive or dead, is never practised. It is easy, therefore, to conclude that when there is no encouragement or legislation to favour the study of Medicine, where anatomy and physiology are scarcely known, and, finally, where the books treating upon the nature, causes, and treatment of disease are based, for the most part, on mere theory and speculation, which have been handed down from time immemorial, the Medical Art in China must necessarily be in a very low and imperfect state. And such is the case ; its people are observing people in all matters readily cognizant to their senses, but not one seems to have been gifted with sufficient powers of observation to have drawn the deductions which Hippocrates did 2,200 years ago ; and, although he was born in a family in which the practice of Medicine was hereditary, was reputed to have been a lineal descendant from Æsculapius, had access to all the records in the schools of the Asclepiadæ of the isle of Cos, and enjoyed the advantages of travel in neighbouring countries, yet he had no opportunity, it is believed, of acquiring a correct knowledge of the structure of the human body, the relation of different parts to each other, the existence of the nervous system, or the true circulation of the blood ; but, though deprived of this knowledge, by the abhorrence with which the dissection of the human subject was regarded at that time (and in this respect he did not enjoy greater advantages than the Chinese), yet he did what they have never done, —he examined animals, and thus by comparative anatomy and the study of disease, based not so much on theory as careful observation, he attained to a degree of medical experience and knowledge which greatly surpasses anything to be found in China even at the present day."

We extract the following from a series of cases of *Clinical Midwifery* by Dr Robert Lee :

"*Case* 662.—On February 3rd, 1854, Dr Richards requested me to see a patient in Stanhope street, Regent's park, who had been upwards of thirty hours in labour with her first child. The pains had almost entirely ceased, and there was great exhaustion. The head, much swollen, was firmly impacted in the brim of the pelvis. An ear could not be felt. We waited eight hours to see if the pains would return, but they ceased completely, and it being obvious that the head would never be expelled by the natural efforts, we resolved to deliver by craniotomy. After the brain had been entirely removed, great and long-continued exertion was required to extract the head with the crotchet. In removing the placenta, which was retained within the uterus beyond the usual period, I ascertained that the base of the sacrum projected forward unusually. The hæmorrhage and faintness which followed ceased, and the patient recovered favourably. After the labour had been happily completed, Dr Richards expressed his surprise, how any Practitioner in Midwifery could venture to apply the forceps to the head firmly impacted in the brim of the pelvis, where there was no room for the blades to be introduced. I stated, as the result of my experience, that fatal contusion of the soft parts was often the result of this injudicious proceeding, sloughing, and vesico-vaginal fistulæ, &c.

"*Case* 663.—On April 14, 1856, I was called by Mr Ridley to see the same patient in her second labour. It had commenced at two in the afternoon, had continued all that night, the whole of next day and night, till the following morning. The head was still above the brim of the pelvis, and there being no hope that it would ever pass, I again performed the operation of craniotomy, and the recovery was most favourable.

"*Case* 664.—The catamenia ceased in the same patient on January 1, 1853. On August 1, having ascertained the exact position of the os uteri with the right index, I passed along this the fore and middle fingers of the left hand, which had been introduced so that the top of the middle finger touched the os, and could be passed into it. The stiletted catheter was then slid along, these passed readily into the uterus two or three inches. The stilet was then pressed forward, and the liquor amnii immediately began to escape. Labour soon followed, but the child was extracted dead. The patient again recovered favourably.

"*Case* 665.—On February 12, 1854, Mr Cathrow requested me to see a patient near the Hampstead road, who was far advanced in pregnancy, and had suffered from repeated attacks of convulsions, with insensibility, but not complete. Symptoms of labour commencing, I perforated the membranes, when a great quantity of liquor amnii escaped. The convulsions ceased, and the labour went on favourably."

"*Case* 667.—On April 24, 1854, I was requested to see a lady at ——, who had been long in labour with her first child. The labour had commenced on the Saturday morning ; had lasted all that day and night, all Sunday and Monday to six o'clock. The soft parts were enormously swollen ; pains entirely gone ; pulse rapid ; complete exhaustion. The common midwifery forceps, without leather or any other covering, had been attempted to be applied at a time when it was certainly known that the child was dead. The bones of the head were overlapping one another ; very fœtid discharge. I opened the head and extracted it after considerable exertion ; the shoulders passed with difficulty. Sloughing and contraction of the vagina followed ; but the patient recovered, and has since been delivered of a living child. On November 1, 1856, this patient was safely delivered of a living child by the natural efforts. As the head advanced, the contracted part of the vagina offered comparatively slight resistance ; the chief trouble was at the outlet. The child is very feeble. The mother doing well. This report was furnished to me by her medical attendant."

"*Case* 669.—Mrs K., aged thirty-eight, May 15, 1854, delivered of her first child in 1848, after a severe labour, during which chloroform was given to her by her medical attendant, contrary to her wishes. She was not wholly insensible, but felt as if delirious. Was not perfectly conscious at the time the child was born, and only remembers that her child was brought to her three days after. She was not able to suckle her child, and an attack of 'incoherence,' or puerperal mania, followed. The perineum was extensively lacerated during the labour, and a portion of the sphincter ani has been destroyed. This was not discovered till long after. She has suffered ever since from a painful sense of bearing down, and has not been able to walk. Dr Lever had been consulted, and recommended an abdominal supporter, from which little benefit has been derived."

"*Case* 671.—Mrs S., aged twenty-nine, Friday, 9 p.m., July 7th, 1854. Being near the full period of pregnancy, the liquor amnii began to escape fourteen days before. Pains did not commence till Thursday the 6th, the day before I saw the patient. Mr —— had made an examination,

and 'found the cavity of the pelvis exceedingly small posteriorly; a projection, but whether a projection of bone, or an accumulation of feculent matter,' he could not ascertain. 'The os uteri still very high up, and slightly dilated; pain still continuing.' I found the hollow of the sacrum blocked up greatly by a mass which was not bone, but, whether ovarian or uterine, I could not be certain. The head of the child was distinctly felt through the abdominal and uterine parietes, which were extremely thin. On carrying the finger up immediately behind the symphysis pubis, I ascertained that the os uteri was high up, and widely dilated, and that an extremity presented, whether upper or lower it was not possible to tell, but my fingers were covered with what seemed meconium. It was impossible to ascertain the presentation without passing the whole hand into the vagina; and this being the first child, a good deal of difficulty was experienced in effecting this. The left hand was found to be the most convenient. With the fore and middle fingers I ascertained that it was a lower extremity, and in a few minutes it was in the vagina; in a few minutes more I had the nates, and the other lower extremity, drawn through the outlet of the pelvis. The crotchet was required to bring down the left arm; the right was brought down without much trouble, and no great force was required to draw the head through the pelvis. The placenta soon came away, and the delivery, which appeared at first so formidable to Mr —— that he thought the Cæsarian operation would be necessary, was safely completed in an hour and a quarter. The tumour after this could scarcely be felt in the pelvis. It was probably ovarian, and had ascended above the brim; but of this I am not yet absolutely certain."

"*Case* 674.—On July 30, 1854, about two a.m., I received the following note: 'Will you be so kind as to come with my assistant and see a patient whom I consider in a dangerous state?' Mr —— informed me that he was called to Mrs J. at seven a.m. The os uteri was dilated to the size of a shilling, and the head presenting. All was going on well, with the exception of a slight cough, and crepitation of the lungs, which she said she had once before suffered from when frightened by a fire. She suffered from attacks of palpitation of the heart, but the husband stated that during pregnancy she had enjoyed good health. I found the patient sitting, or rather supported or held up, in a state of urgent distress from difficulty of breathing; livid lips; cold, clammy extremities; rapid, feeble, irregular pulse. She could not lie down, and it seemed very probable, if not immediately relieved, that she would die undelivered. Mr —— said he contemplated using the short forceps. The patient had taken ℥iij. of ether without relief; ℈j. of sulphate of zinc had been given without vomiting being induced. No relief had followed these remedies. A mustard poultice had been applied over the chest. The distress could not have been greater, and it seemed probable she would speedily die if not delivered. We had no doubt about the necessity of immediate delivery. The os uteri was not more than half dilated, and the head had not passed into the pelvis. Only the top of the head could be felt. I stated that the idea of using either the long or short forceps was entirely out of the question, because the os was not fully dilated, and because the head had not passed through the brim of the pelvis. The patient could not lie a moment on the left side. She was brought to the edge of the bed; the feet were placed upon a chair. I had some difficulty, being upon my knees, in reaching the head with the perforator, but I succeeded in opening it and evacuating the brain without much difficulty, and extracted the head with the crotchet. No difficulty with the shoulders, and the placenta soon came away, a little traction being made on the cord. No binder or pressure over the uterus could be borne. In a very few minutes relief took place. The lips became less livid, the breathing and the pulse better, and in twenty minutes she was smiling, and able to express her gratitude for the relief she had experienced. On the following day she was as well as could be expected. The countenance was still turgid; dyspnœa slight, especially when asleep. Six leeches applied to the chest. The day following, still breathing with some difficulty; wheezing in the chest; irregular action of heart; pulse rapid and irregular. A blister had been applied. A Medical Practitioner who saw the patient yesterday suggested that the sudden attack of difficulty of breathing might be puerperal convulsions falling upon the lungs. Recovery complete in a few days."

"*Case* 676.—On August 20, 1854, I saw a young married lady who had been seized with convulsions at the commencement of her first labour. The liquor amnii had escaped three days before. The os uteri being rigid, and the fits recurring, ℥xxiv. of blood were taken from the arm. Labour went on, and the child was born alive, but the fits returned at longer intervals. Some hours after her delivery, when I first saw her, she was completely insensible, but could swallow; pupils little dilated; pulse rapid and feeble; ℥xx. of liquor opii sedativus had been given; ten leeches were applied to the temples, and ice in a bladder to the scalp; the fits gradually ceased, and consciousness returned.

"*Case* 677.—At eleven a.m. on September 7, 1854, I was called in great haste to a patient near Islington in labour, who was represented to be in extreme danger. When I arrived at her residence, I found her dead. She had been delivered at nine a.m., two hours before, with the forceps. The perineum had been extensively lacerated, and I suspected that other parts, of still greater importance, had been injured, but I was not permitted to ascertain the exact state of the parts. There had been no hæmorrhage to account for the death. The labour had been protracted, and the forceps had been applied without a consultation with any other person. I had not previously met the Medical Practitioner who had the care of this unfortunate patient; but the unconcerned way in which he spoke of 'clapping on the forceps,' rather led me to fear that, in this case, the necessary caution had not been observed in the employment of the instrument.

"*Case* 678.—Monday, September 25, 1854.—On Thursday week Mrs B. had an abortion at the third month. The embryo came away, but not the placenta and membranes. The os uteri was found closed by Mr ——, and it could not be removed. The following Wednesday, hæmorrhage took place, and Mr B. was called to see the patient, her medical attendant having been necessarily absent. It was stated to Mr —— by the nurse that she believed the placenta had come away. The ordinary medical practitioner returned, and has been in attendance since, and has acted on this impression. The patient had been seized with fever and vomiting, and champagne had been freely given. The pulse was rapid, tongue furred, with constant sickness and vomiting; fetid discharge. I asked who had seen the placenta, but it appeared it had not been seen by any one. I requested the patient to turn on the left side, and found the whole mass of the placenta in a very decomposed state in the upper part of the vagina and os uteri. I removed it completely, but in pieces. The vagina was washed out with warm water, some aperient medicines given, and the patient was soon quite well."

The 'American Medical Monthly' contains an article, by Dr FOUNTAIN, on the *Treatment of Phthisis by Chlorate of Potash, with Observations on Oxygen and Ozone as Therapeutic Agents.* The Author believes that chlorate of potash is a useful remedy in phthisis by supplying oxygen to the blood, and cites some cases. We quote the following:

"*Case* II.—Mr M——, aged twenty-five, family consumptive on mother's side, applied to me for treatment, Nov. 5, 1859. Had been living for about two years in Omaha, Nebraska. Health usually good during a number of years past, until within the three or four months previous to calling upon me. Has been coughing for three months, during which period he has expectorated blood several times. Strength gradually failing, losing flesh, and appetite entirely gone. He assured me that for two months he had not taken nourishment sufficient to support properly the strength of an infant; and his emaciated and bloodless appearance corroborated the statement. He had some soreness in the throat, and complained of pain occasionally on the right side. Cough very frequent night and day, but very seldom any expectoration. His debility was so great, that he fainted from the effort of standing erect to permit a physical examination of the chest. The left lung appeared to be perfectly healthy, but there was appreciable dulness over the middle and upper lobes of the right. Over this region of dulness the respiratory murmur was very feeble and indistinct, and the expiratory sound nearly equal in duration. His respiration and pulse were increased in frequency on the slightest exertion, and he complained much of great oppression in breathing. He had not the slightest desire to eat at any time, and seldom more than tasted food.

"*Treatment.*—In this case I decided to test the chlorate of potash alone before giving anything else, that I might not confound the effect of different remedies, and thus be able to determine more accurately the properties of the one under investigation. I therefore prescribed half an ounce to be taken daily in the same manner as in the preceding case. This was on Nov. 5.

"Nov. 8th.—Decided improvement; cough less; oppression greatly relieved.

"10th.—Still improving, and beginning to have a little appetite.

"Satisfied by this time that the chlorate was having a decided effect in the manner I anticipated, I now thought it proper to aid the treatment by prescribing iron and quinine in small doses daily, and continued the chlorate of potash the same, half an ounce each day.

"6th.—Cough very slight; no pain in the chest; full inspiration taken with less difficulty; general appearance decidedly better.

"19th.—Improvement continues unabated. From this date I reduced the chlorate of potash to three drachms daily.

"23rd.—Patient considers himself almost well. Appetite good; no cough; gaining strength and flesh quite rapidly; still a slight degree of dulness on the right side; but respiratory murmur more natural. Continue the chlorate of potash in drachm doses three times a day, and omit the iron and quinine.

"Soon after this he left on business for the East, and on January 18th following he addressed me a letter relating to his health from Washington City, D.C. He had continued taking the chlorate of potash most of the time. He invariably felt worse by omitting it, and renewed strength and general improvement when he returned to its use. In this letter he says: 'I have no cough, but occasionally some difficulty in breathing; but not near so much as when you first saw me at Davenport in the fall. My strength has improved a great deal, and generally my appetite is quite good.'

"*Case* III.—Mr H——, aged thirty-four, placed himself under my care early in Nov. 1859. He had the appearance to every one of a man sinking under the influence of confirmed phthisis. To this he was predisposed from his father, who died young with this disease—mother still living and well. A gradually-increasing cough and failing health had been gaining upon him for the past five years.

"Once during this period he had improved under the use of cod-liver oil and phosphate of iron. Free, and quite profuse, hæmorrhage from the lungs once, and slight traces of it a number of times during the past year. When he applied to me, he was conscious of losing strength very fast. Marked emaciation, and unhealthy expression of countenance; very frequent cough, but seldom any expectoration; no appetite; respiration hurried and oppressed; pulse seldom below 90; moderate dulness on the right side, over the infra-clavicular region; no râles, but respiratory murmur indistinct and irregular. As he had once been benefited by cod-liver oil and the phosphate of iron, I first prescribed this same treatment, thinking it might again have a similar effect. This was continued faithfully for about two weeks without any material benefit, when I directed it to be discontinued, and prescribed the chlorate of potash alone, half an ounce daily, as in the above cases. In less than a week he assured me that he felt a decided benefit from the treatment. The improvement continued steadily from this time, and he completely regained his health and strength in less than three months. *He took half an ounce of the chlorate of potash daily for six weeks,* and two drachms each day for the succeeding four weeks; since which time he has taken it only occasionally, and in smaller quantity. At the present time of writing (April, 1860), he is actively engaged in business,

in good strength and flesh, having no cough, except a trifle from a recent cold; complexion perfectly healthy, and appetite good. His own feelings and general appearance indicate a perfect restoration of health.

"*Remarks.*—Although these cases are not sufficient to verify the prediction which I ventured to make nearly a year ago, they certainly furnish strong presumptive evidence in its support. Of themselves they are sufficiently striking to merit the attention of the Profession, irrespective of any particular theory which prompted the treatment. But cases reported can be regarded as contributions to science only as they sustain or reveal some principle of general application. In these cases, although the treatment was purely experimental, it was not empirical; for the chlorate of potash was given on the assumed principle of *conveying oxygen to the blood*, by which I expected to relieve the lungs of a portion of their task; increase the vital power of the blood, and render it more capable of faithfully performing all its functions; and by which tubercular deposits might be arrested, and absorption of those already formed promoted. So far as I have yet been able to test the practice, the results have more than realised my anticipations, and sufficient at least to justify me in laying the subject before the Profession. Whatever may be the result of a more extended experience, some important facts are established by the foregoing cases, and others which have been elsewhere reported.

"1. The chlorate of potash can be given in large doses every day, for a long period, without injury.

"2. It aids the functions of respiration by supplying the blood with oxygen.

"3. It operates as a natural *tonic*, *alterative*, and *blood depurant*, by increasing the supply of that element which is the most active agent of nature in the chemical changes which take place in the laboratory of the human system.

"I will now add, that in the practical application of these principles, it is my belief, which may or may not be confirmed by the experience of others, that it is a peculiarly appropriate remedy for the *early stages of phthisis*, by which the resolution and absorption of incipient tubercles may be effected, and their further deposit arrested. Even where the disease has progressed to the second stage, I have found patients derive great benefit from the use of this remedy; more, indeed, than from all others, single or combined. I cannot, however, expect it be of permanent benefit, only in the early stages of the disease, before there is any disorganisation of the lungs or suppuration of the tubercles. To all who are labouring under the symptoms of this disease, before it has progressed to such an extent, I would recommend the liberal and constant use of the chlorate of potash, aided by appropriate hygienic treatment, in which exercise and pure air hold the rank of first importance. Half an ounce daily is the quantity I usually give, when I wish to produce a decided effect for any purpose, and this can be taken certainly for many weeks with impunity; but when I have occasion to give it for a long time, I find three drachms a day can be depended upon as sufficient in most cases. After all symptoms of phthisis have been arrested by this treatment, it should still be continued for a time in moderate doses, and always resumed as soon as the slightest symptom of its return is manifested. In addition to this treatment, I would recommend as a daily beverage a trial of liquids artificially charged with oxygen gas."

The Author does not consider oxygen gas as an appropriate remedy for phthisis. His views of the nature of ozone are thus expressed:

"I shall venture to affirm that *ozone is simply oxygen in a nascent condition, produced naturally by electrolytic decomposition of the vapour of water in the atmosphere.* It is a law in chemistry that all gases, when in a *nascent* condition, possess properties and powers which are peculiar to that state. In this manner gold is dissolved by the nascent chlorine generated in the *aqua regia*; and the bleaching power of chlorine is due to its strong affinity for hydrogen, by which the water of the dampened fabrics is decomposed, and the oxygen liberated; and this nascent oxygen, or ozone, is the true and proximate bleaching agent. As a disinfecting agent it probably acts in the same way, by decomposing the vapour in the atmosphere and liberating the oxygen.

"Electrical currents are constantly and silently passing around the earth, following the direction of the sun; and upon the combined effect of the degree of intensity of these currents, the discharges of electricity from the clouds, and the amount of vapour, depends the varying proportion of ozone in the atmosphere.

"It is not oxygen electrified or hydrated, but oxygen generated from the decomposition of water or the vapour of water; and it is ozone only at the time of this decomposition. It is not a thing of itself, which can travel with the air and be separated from it, but a manifestation of peculiar properties of oxygen when in a certain condition, which may be termed *dynamic;* and these properties can be manifested only at the time and place of the liberation of oxygen from some chemical combination. This will explain why it is that ozone cannot be produced in an atmosphere which is *perfectly dry*, and also why it is not found within a dwelling or under the shade of the forest. The currents of electricity at all times flowing through the atmosphere are interrupted and pass to the earth through the medium of any prominent structure or forest-tree. They pass down through the walls of our dwellings and circulate not in the atmosphere of our rooms, and therefore we find no ozone there; and the trees of the forest also act as conductors to these electrical currents, and thus prevent the development of ozone beneath them.

"In the laboratory, by means of phosphorus, the phenomena of ozone can be made to appear without the aid of electricity, *but never without water.* And so in the atmosphere, ozone can never be produced by natural agencies without the presence of the vapour of water."

The 'Dublin Medical Press' contains the following observations by Mr Hugh Croskery on the *Intermittent Fevers of the West Indies*, and on the action of Quinia as a specific in the treatment thereof.

"I have always found that the exhibition of a full mercurial purgative, which, if necessary, may be repeated, will materially assist the legitimate action of the quinia, while it will remove from the system quantities of morbid matter. Where the tongue continues furred and loaded, and the mouth parched, the calomel should be repeated, and followed up by a cooling draught of sulphate of magnesia, so that all morbid secretions may be removed. If this be neglected, the quinia will act prejudicially, and the fever may assume a typhoid character. I have lately heard of a case where the paroxysms were complicated with strong convulsions, alternated with low muttering delirium, and where, although the intermission was perfect, and quinine was administered in quantities, the paroxysm returned with increased severity, and with a fatal result. In this case, doubtless, the secretions were in the most depraved condition, and the quinia had an opposite effect to what was intended. Had remedies been administered with the view to preserve internal organs from injury, and to remove morbid secretions during the paroxysm, the result might doubtless have been different.

"But this practice of giving quinia indiscriminately cannot be too loudly condemned. Where a foul tongue and insatiable thirst exist, with a tendency to apoplexy or coma during the hot stage, the secretions are in the most vitiated condition, and no time should be lost in thoroughly clearing out the bowels, and in removing all morbid accumulations. If such active treatment be neglected during the fits, local affections will certainly be established by the smallest quantity of quinia given during the intermission. Quinia is, certainly, a safe and certain specific for intermittent fever, when the system is kept saturated with it, without irritation or inflammation of any internal organ being superinduced, and when its legitimate action is not impeded by the presence of morbid biliary or alvine secretions.

"By getting the quinia quietly and gradually into the system, a very large proportion of it (from forty to sixty grains) can be administered without causing the slightest unpleasant sensation, while a single ten-grain dose will produce violent head symptoms (in most cases), without *affecting the system.* The consequence is, that the dose cannot be repeated with safety, and that the paroxysm returns as before. If, however, the system be gradually and quietly saturated with the salt, as it most certainly will be, after the exhibition of forty or sixty grains, and this effect be kept up by continuing its administration every third, or fourth, or fifth hour, the fever will be entirely eradicated, and the paroxysm will not return; or if it should do so, it will be in a very mild form, and will continue for only a very short time, as will be seen in Case 4 of this paper. In this, and all such cases, however, where there is even the slightest return of the paroxysm, either the system had not been sufficiently saturated during the intermission, or the effects of the salt have been allowed to subside too soon. In order to insure complete exemption from a return to the fever, the action of the quinia must be kept up by the continued exhibition of small doses at longer intervals, after some decided effect has been produced on the cerebro-spinal system; and I maintain that, if this effect be only kept up, and not allowed to subside, the paroxysm cannot possibly return. Such has been my experience, and this opinion is advanced, not hypothetically, but as the result of actual practice. Like mercury, quinia produces a disease *sui generis*, in which the cerebro-spinal system is principally affected, and which, while it continues, is directly antagonistic to the affection for which it is said to be a specific. To produce, then, this effect, we must proceed cautiously, lest the system be overpowered by too large a dose, and a violent and sudden action be the result. What is wanted, is complete saturation of the system, and the continuance of this condition, until the period of two or more paroxysms has elapsed, without much cerebro-spinal excitement being induced. This is especially to be avoided, as, while it lasts, the administration of quinia must be discontinued, and its action allowed to subside before another dose can be given. In such a case, there would not only be a possibility, but an absolute probability of a return of the paroxysm. If, as Muller says, intermittent fever is essentially a nervous disease, and quinia causes, when given in large doses, intense cerebro-spinal excitement, surely it is almost madness to attempt to cure such a disease by the administration of such doses of this salt, during the intermission, as will convert a healthy—for such is the intermission—into an unhealthy and morbid action?

"The day will yet come, and, I hope, is not far distant, when it will not only be in the power of every physician to cure the most aggravated cases of this most troublesome and dangerous malady, but also of the non-medical public, at least of a country like Jamaica, where, in some districts, one man has to minister to the medical wants of ten thousand inhabitants, to put an effectual check to the disease, whenever it appears amongst them. So frequently does this disease attack even the most acclimatised, that there is scarcely a single house of any respectability in the island of Jamaica where an ounce or half-ounce bottle of sulphate of quinine is not to be found in the medicine-chest!

"I have shown, and I will give further proof by reports of cases, that even the most aggravated attacks yield to proper treatment.

"Drs Bailie and Pitcairn recommend the administration of calomel, in doses of one grain every night, as an adjuvant in the treatment of intermittent fever by any of the preparations of bark: my experience, however, will not allow me to agree with these gentlemen, as I have seen the worst results follow this practice. A brisk mercurial purgative is, however, a very considerable adjuvant to the action of quinine, as it clears away morbid secretions.

"As far back as the 17th century, it was found out that bark, or any preparation of it, could not be administered with safety or advantage during the paroxysms, as it not only produced cerebral congestion and excitement, but actually prolonged the period and increased the violence of the fit: hence it was that Sydenham, after long and deep reflection, 'diu multumque apud se agebat,' proposed the aphorism 'to administer the bark in the intervals, instead of in the paroxysms of a fever.' This excellent advice was not given hypothetically, as Sydenham, at one period of his life, was directly opposed to the administration of bark at all in fevers, from seeing the bad effects of it when given either in large doses or during the paroxysms, but after long and earnest trial, and when he had practically convinced himself that its failure, as a specific, depended, not on the bark itself, but on the improper administration of it. This rule holds good, even at the present day; and if fevers are not cured by quinia, it is because some medical men will adhere to doctrines condemned 170 years ago, and will not be convinced of the impropriety of their practice. During the fit, there is a determination to particular organs, according to the idiosyncrasy of the individual or his habits of life, and, in most cases, the head symptoms predominate. So that, if this be the case, and if quinia tends to excite the cerebro-spinal system, surely even the smallest dose will have a mischievous effect if given during the existence of a paroxysm.

"Again, if the paroxysm be associated with a cerebro-spinal affection, or any tendency to it, and quinia be given in large doses during the intermission, surely there is every chance of this cerebro-spinal complication becoming either exaggerated or developed during each succeeding paroxysm, as it is well known that large doses of this salt have a tendency to inflame congested organs? Of late years, medical men have been in the habit of prescribing quinine in much larger doses than formerly, although Bretonneau and others have called attention to dangerous results which frequently follow this practice."

Five cases in illustration are then reported.

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Untamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

THE MEDICAL CIRCULAR.

WEDNESDAY, OCTOBER 31, 1860.

THE MEDICAL OFFICERS OF THE INDIAN ARMY.

Two years have now elapsed since Her Majesty issued her Warrant to improve the position and pay of the Medical Officers of the British Army. It was expected, as a thing of course, that the Royal Warrant would command obedience in every region where the Royal Troops were acting in the service of their country. It could not be anticipated that Her Majesty's authority would be limited by temperature, geological strata, conventionality of administration, prejudices of class, or any of the thousand obstacles and refinements which occasionally impede the fulfilment of the designs of her humbler subjects.

It has been well said that the sun never sets upon the Queen's dominion. Her Royal mandates fly to the uttermost parts of the earth, and are supposed to strike high-spirited Governors with awe, and to astonish refractory natives into submission. We fondly believe that our Queen is the supreme embodiment of British sovereignty, that Victoria is a name to conjure with, that the Chinese Mandarin holds it in profound respect, especially when pronounced by the stentorian lips of a sixty-eight pounder, and that the African Black considers it to be the only articulate name of the great spirit that is the overruling Providence of his destiny.

Like many other sublime notions, it appears that this is an illusion. The Queen of Great Britain is not so paramount as we suppose, and the Right Hon. the Earl Canning is a much more important personage—at least in India. Events seem to make this conclusion too clear.

We are informed by the 'Indian Lancet,' that the Medical Officers of the British Army serving in the Bengal and Bombay Presidencies have recently memorialised his Lordship, requesting to know "the reason why" Her Majesty's Warrant has not yet been acknowledged in India, and become the law of the Service. This is a very reasonable request. The Indian Army is an integral part of the British Army. It acknowledges the same head, fights under the same flag, is liable to the same perils, and undergoes even greater hardships: why, then, should there be any unnecessary difference in its internal administration?

Her Majesty's Warrant "has been recognised and acted upon in every country acknowledging British supremacy," except India; and here the Medical Officers have enjoyed none of the advantages of rank, consideration, and pay which the Warrant was intended to confer. The Medical Officers of the Indian Army are placed under greater difficulties, perform at times more important and responsible functions, and are more liable to wearing anxieties and physical trials, than their brethren in the regiments at Home Stations. In consequence of the nature of the climate, their routine duties are heavier and more oppressive, and their health and lives are in more imminent peril. Surely, then, these gentlemen have a strong claim to justice. It seems strange to us that they should condescend to argue their case upon any other ground than that of their *right!* They are entitled to the same pay and privileges as their brother-officers—and nothing less. Every other claim but that of plain, even-handed justice is beside the case, and weakens it.

The *injustice* of their case, as it at present stands, is very apparent. The Assistant-Surgeon of a home regiment has the substantive rank of *Captain*, and draws the pay and allowances of that rank; he is ordered to India, and directly he puts his foot upon that inhospitable soil he is virtually degraded, being recognised and paid only as a *subaltern*. Englishmen will not long submit to such wrong without complaint.

This is not, however, the whole of the grievance. The Government of India, having regard to the exigencies of the climate, the expense of living, and incidental social necessities, has granted an increase of pay of from two to five times that allowed at home to all commissioned officers, except those of the Army Medical Department! The result is, that the Assistant-Surgeons of the Indian Forces lose, by serving in India, "from four to seven pounds sterling per mensem," not including in this loss the allowances which are granted at home, but not permitted in India.

Such is the case of the Medical Officers of the British Army in India. These are real grievances, and demand instant redress. Service in India, under present circumstances, is a penalty, and must be regarded with aversion by every Medical Officer. We have often noticed a complaint that there is a deficiency of candidates to fill up the vacancies in the appointments to the Army Medical Service; and much surprise has been expressed that such noble prizes should invite so few competitors. We now see what the real value of these appointments is; and so long as the injustice we have described continues, so long will the junior members of the Profession be reluctant to engage in so arduous and ill-requited a service. It is for the interest of the Army itself, as well as for the honour of the Indian Government, that the grievances of the Medical Staff should be redressed, and these gentlemen placed in every respect on a footing of equality with their brethren serving in England and her dependencies.

SUMMARY OF THE WEEK.

SIR BENJAMIN BRODIE AND THE ROYAL SOCIETY.

It is with regret we have heard that, in consequence of his continued impairment of vision, Sir Benjamin Brodie has deemed it necessary to resign his post of President of the Royal Society. Though this resignation was not wholly unexpected, it has nevertheless caused much pain among the Fellows, and accordingly, at a recent meeting of the Council, it was agreed that a request should be made to Sir Benjamin to allow himself to be nominated again for the Presidency. His incumbency of office during the past two years has given much satisfaction, and it is hoped that in a short time his sight will have so much improved as to enable him to discharge the duties of the post. We most sincerely hope that this expectation will be realised, and that the career of his usefulness will be extended.

SUICIDE BY VERMIN-POWDER.

A domestic servant of the name of Ann Collins lately destroyed herself at Cheltenham, by taking "Broad's Vermin-Powder." Strychnia was discovered by Mr Horsley in one of the powders, so that there can be no doubt about the poisonous ingredient of this vermin-killer. We should like to know how this girl obtained the powders, and what were the precautions used by the druggist who sold them? We fear that the sale of this and similar articles is unguarded by any adequate precautions, and that any servant-girl who is love-sick, and has a fancy to kill herself, can do so at any time at the cost of a penny expended upon the purchase of vermin-powders. At one time, arsenic was the favourite poison for this purpose; but the Legislature put a prohibition upon its sale, by requiring it to be mixed with charcoal, and imposing certain restrictions. Until legislation be carried out in the same spirit with reference to other poisonous articles, the papers will continue to report cases of suicide by their use. The salutary effect of past legislation should encourage Parliament to take other steps in the same direction.

STRANGE DOINGS IN THE MARYBOROUGH DISTRICT ASYLUM FOR THE INSANE, IRELAND.

The newspapers of the sister-country have been affording astonishment of late to the general public, by reason of revelations of a

most extraordinary nature in connection with the management of the above-named establishment; and all evidently arising out of the insane practice of permitting an extern functionary, designated a "Visiting Physician," to exercise an authority greater than that of the really working and responsible officer, the Resident Superintendent Physician. It naturally surprises us in this country to learn of such an arrangement as the above, which was so properly brought under the consideration of the "Association of Medical Officers of Asylums and Hospitals for the Insane," at their last annual meeting, and, after a full discussion, was unanimously denounced by that body as wrong in principle and bad in practice. The proceedings now in question must necessarily, we conclude, give a deathblow to a system so pregnant with evil to the best interests of our public institutions for the treatment of insanity in the sister-country; and all having their welfare at heart should rejoice that such an *exposé* has been made as must compel the proper authorities to "mend their ways" in a matter so grave and so deeply important. A reference to the condensed report contained in our pages to-day of the investigation at the Maryborough Asylum will, no doubt, amaze our readers on this side of the Channel; for it "a tale unfolds" of oppressive misrule and interference, by a merely extern functionary, of the most marvellous nature in all its bearings. The redoubtable "Visiting Physician" of tho "Maryborough" would appear to be a genuine Ishmaelite, in direct line from that "wild man" of the desert whose "hand was against every man, and every man's hand against him." The poor lunatics themselves, even, held him in such estimation that the services of a body-guard had to be put into requisition ere he could venture amongst them!! Officers, attendants, and servants were constantly kept in scalding hot water by the unprecedented course of proceedings which he has been permitted to pursue with so high a hand in this devoted Asylum. What, let us ask, was its Committee of Visitors, the Government Inspectors themselves, and the Executive Government of the country about, that such a miserable and disorganizing state of things was permitted to run riot so long? It is to be hoped, if a continuance of the same be not at once and thoroughly provided against, that the whole matter will be brought before Parliament by some independent Member, and the Irish Asylums freed, for all time to come, from the baleful presence of extern officers whose delight, as in the present instance, was in exercising authority—such should never have been given—in a manner so as to "embroil everything" within the walls of the Asylum. We have only, in conclusion, to remark that Dr Burton was a man in a thousand, to put up so long with the treatment pursued towards him.

MR BAKER BROWN AND DR EBEN WATSON.

A few weeks ago, Dr Eben Watson forwarded to us an angry letter reproaching us for having permitted the insertion of some remarks prejudicial to his Professional character, and lecturing us on the proper mode of discharging our Editorial duties. We thought that it would be but kind to Dr Watson not to publish his rash epistle; we therefore contented ourselves with simply noticing it in our column to Correspondents, and expressing our regret if his feelings had been wounded by inconsiderate remarks. It is not in our power, however, to arrest the arm of Nemesis. Other men have characters as well as Dr Watson; and although we may care little about what men like Dr Watson may think or say of ourselves, we must, as the guardians of scientific truth and professional courtesy, protect the reputation of all cultivators of science who have been wrongfully aspersed. Our readers will see from a letter in another page, that Mr Baker Brown's practice has been carelessly and unwittingly, we trust, but, nevertheless, most egregiously misrepresented by Dr Eben Watson. Instead of nineteen cases upon which that gentleman had operated up to the time of Dr Watson's article, there were actually twenty-nine; and instead of four unsuccessful cases, there was only one. As to the "special pleading,"—for it can be called nothing else,—about twenty-five operations in one case, and adding these to the aggregate number of operations for the express purpose of diminishing the degree of success, we leave that to the common sense and fairness of our readers. We now hope that when Dr Eben Watson next engages in scientific investigations, he will see the propriety of being more accurate in his research, and more temperate in his judgment; and that when he indites an epistle to the Editor of a Journal, he will deem it expedient to be more charitable in his opinions, and more gentlemanlike in the language he may please to employ.

WANTED AN EDITOR!

The 'Association Journal' must be in a bad way, for we observe that its friends are advertising for an Editor. Dr Wynter has resigned his charge, as Dr Cormack, Dr Ranking, &c. &c., did before him; and now who will be bold enough to take service under two thousand masters? This resignation affords a fair opportunity to adopt the suggestion of one of the members, to the effect that the Editorship should be put in commission, and that each of twenty-six gentlemen should write two leading articles a year. It would be a pity that the Society should lose the chance of developing such a phalanx of editorial ability. In a short time, Editors will become as cheap as stale mackerel, and the Association will be able to satisfy its literary needs at a small cost. Before Dr Wynter leaves the 'Journal,' we advise the twenty-six gentlemen to give the subscribers a specimen of their abilities. We shall have no objection to act as umpire; but we beg to intimate beforehand that we shall insist upon the observance of nine essential conditions: first, that the writers do not expatiate on Medical politics—or, if by a special indulgence they do so, they must take care not to offend Sir Charles Hastings or Dr Richardson; secondly, they must never treat of Medical Science, because it's dull, and the 'Journal' is dull enough already; thirdly, they must not joke, for that's vulgar—nor be grave, for that's pedantic; fourthly, no gentleman must puff himself, for that's derogatory—nor his friend, for that excites envy; fifthly, they must not reprove anybody, lest they should lose a subscriber—nor have a single opinion of their own, lest they should bring down upon them a shower of hostile communications; sixthly, they must do as they are bid; and seventhly, eighthly, and ninthly, they must write, not with ink, but with a nicely-flowing pale-blue, neutral milk-and-water. If they fulfil these conditions, they shall be invested with our authoritative commission to write leaders for the 'Association Journal.'

REVIEWS.

The Surgical Diseases of Children. By J. Cooper Forster, F.R.C.S.

Mr. Cooper Forster has produced a very useful book, which, without any pretension, gives a brief and lucid account of all and each of the affections susceptible of surgical treatment to which children are liable. We have many treatises devoted to the elucidation of the diseases of children; but all these works, having been written from the Medical point of view, treat largely of the hygienics of infantile life, and are copiously interlarded with prescriptions. Mr Forster has eschewed this form of work, and has confined himself to a practical treatment of his subjects. He has noticed every affection, however trivial or important, from tongue-tie to calculus, and has directed attention to some forms of disease which are not common, but when occurring in the course of practice are difficult to manage. For instance, he has described a strumous ulceration of the face, "frequently of one or other cheek; irregular in shape, apparently inclined to heal in one part while spreading in another; the edges thin and eroding; no appearance of granulations; the surface of the sore smooth and shining, as well as the surrounding integument; the discharge watery, rarely purulent; a part of the sore has frequently scabbed over; and if a part has healed, there is a puckering of the new skin." This disease is generally associated with evidences of strumous disease in the glands or joints. We quite agree with Mr Forster that escharotics are injurious; indeed, we have seen this peculiar affection spread from the irritation they cause. Our reliance must be placed upon time, and the general improvement of the health by appropriate remedies. It is unnecessary to quote from a work which is characterised by the brevity of its descriptions, and the purely practical nature of its remedial recommendations; but it is a work we can recommend to the notice of the young Practitioner.

On Eruptions and other Forms of Cutaneous Disease requiring the use of Mercury, &c. By Thomas Hunt, F.R.C.S. Third Edition, revised and enlarged.

Having noticed the earlier editions of this work, it is unnecessary to do more now than to state that the Author strenuously urges the use of the mercurial treatment in the syphilitic forms of cutaneous disease.

On Organic Polarity. By H. F. Baxter, M.R.C.S.

We gather from our Author that there are two schools of electrical philosophers—one represented by Mr Grove, and the other by Professor Faraday, and that the Author has come under the influence of Faradisation. We must confess that, without knowing much about the subject, we, too, go for Faraday. We must, however, let the philosophers settle it. With respect to Mr Baxter, we may state his views to be, that the actions which take place in the living body, whether of secretion, absorption, or nutrition, are accompanied with the manifestation of *current force*, and therefore present the marked characteristic of *polarity*. Eschewing the phrase *vital* force, Mr Baxter styles this *organic* force. The "consequential results" deduced from these investigations are, *first*, that the blood is in an opposite electrical state to the secreted product, as well as to that of the muscular and nervous tissue, and that this state is *positive*. Out of these opposed electrical states the phenomena of irritability, sensibility, contractility, &c., arise. Mr Baxter says:

"The questions which physiologists will have to decide appear to me to be reduced to the two following: 1st, Is the electric condition of the nerve merely a condition necessary for the manifestation of nerve action? or, 2ndly, Is the electric force *converted* as it were into nerve force *during* nerve action? Now if the *decrease* in the nerve current, which I have observed to take place under these circumstances, be due to a *loss* of the electric force, and not to a disorganisation of the tissue, which I have supposed it to be, then we get evidence of the *conversion*, as it were, of the electric force *into* nerve force. We need not expect to have any great effect upon, or any great loss in, the nerve current, as an *equivalent* during this conversion. The quantity of electricity associated with a grain of water, and evolved during its decomposition, its *equivalent*, when existing in the static form, as in a charged Leyden jar, equals that of a violent thunderstorm; and so in regard to nerve force the electricity manifested as nerve current, a loss only of 3 or 4 degrees might be equivalent to its conversion into nerve force, but then I think we have a right to expect that the *decrease* in the nerve current, to whatever amount it might be, ought to be sudden and definite."

As an illustration afforded by Mr Baxter of a philosophic muddle, as well as of the peculiar views of the Author himself, we extract the subjoined paragraphs:

"Dr Carpenter, in a valuable paper 'On the Mutual Relations of the Vital and Physical Forces,' speaking of the term *germ force*, as employed by Mr Paget to designate the power which each germ possesses 'to develope itself into the perfection of an appropriate specific form,' adds, 'so far from regarding the whole force which produces the evolution as being possessed by, or as residing in, the germ, it will be the Author's object to prove that it is of *external* origin.' . . . 'That the vital force which causes the primordial cell of the germ first to multiply itself, and then to develop itself into a complex and extensive organism, was not either originally locked up in that single cell, nor was it latent in the materials which are progressively assimilated by itself and its descendants; but is directly and immediately supplied by the Heat which is constantly operating upon it, and which is transformed into vital force by its passage through the organized fabric that manifests it.' Now the influence of external agencies upon the development of an organism is not to be denied; but when we speak of Heat being converted into vital force, or that Light is converted into vital force, that Heat and Light are absorbed as it were and converted, we are then considering these *forces* as entities; not that Dr Carpenter goes to that extent, for he speaks of the necessity of a *material substratum*; but the language employed leads to this conclusion. The error arises from the employment of the term *conversion*, which expresses inadequately the meaning that is intended to be conveyed by it. When we speak of electricity being converted into magnetism when a current of electricity traverses a helix, the two forces, magnetism and the current, are produced and exist at the same time; there is no change of the electric current into magnetism. Conversion implies a change, a loss on one side and a gain on the other.

"Faraday commences the 'Nineteenth Series of his Researches' with stating, 'I have long held an opinion, almost amounting to conviction, in common, I believe, with many other lovers of natural knowledge, that the various forms under which the forces of matter are made manifest have one common origin; or, in other words, are so directly related and mutually dependent, that they are convertible, as it were, one into another, and possess equivalents of power in their action.' Dr Carpenter observes, 'starting with the abstract notion of Force, as emanating at once from the Divine Will, we might say that this force, operating through inorganic matter, manifests itself in electricity, magnetism, light, heat, chemical affinity, and mechanical motion; but that when directed through organized structures, it effects the operations of growth, development, chemico-vital transformations, and the like; and is further metamorphosed, through the instrumentality of the structures thus generated, into nervous agency and muscular power.' It appears to me, that we should be justified in considering this Force which Dr Carpenter speaks of to be Polar Force, and that the different *forms* under which the various forces are made manifest, as electricity, magnetism, heat, light, &c., are merely different manifestations of this one Polar Force, and therefore have a common origin. One great object experimentalists have to determine is the polar character of the phenomena, and to point out the connecting links which bind these different phenomena together.

"From the facts recorded in the present essay, we can come to no other conclusion than that *the force manifested as organic force in organized beings is a polar force*. The influences which these external forces, heat and light, have over organic development is not so *direct* as would at first sight appear; their influence is not to be doubted, but they appear to be excited in inducing changes of a chemical nature. Heat and Light without moisture and food would have no influence over organic actions; and it is questionable whether there is any loss of heat or of light indicating a conversion, as it were, of those forces into organic force during the development of the organism. The connection, the relation that exists between organic forces and physical forces is manifested by the polar character of the phenomena, by the manifestation of current force during organic actions; and perhaps it would be more correct to say, that the chemical force of inorganic bodies is converted during nutrition and absorption of food into organic force; and, consequently, the same influences may be expected to be exerted by heat and by light over organic actions, as are exerted over ordinary chemical actions."

Such of our readers as may feel an interest in following out the experiments and arguments which form the basis of these conclusions, must refer to the little treatise itself for the gratification of their curiosity.

An Expository Lexicon. By R. G. Mayne, M.D.

This is the tenth part of this admirable work, and well sustains the character of its predecessors.

Obstetrical Society of London.—On Wednesday, November 7th, at eight o'clock p.m., Dr Tyler Smith will read a paper entitled, "An Inquiry into the Correctness of the Doctrine of William Hunter in regard to Retroversion or Retroplexion of the Gravid Uterus."

READINGS FROM FOREIGN JOURNALS.

LARYNGOSCOPY.

Laryngoscopy goes on pursuing its investigations, and, with patient industry, accumulates elements which will one day contribute to a complete history of the affections and lesions of the organ of voice. While waiting till science shall be in a position to derive from this new mode of exploration all the advantages the practitioner has a right to expect, we shall continue our exposition of such results as come under our notice, and now give some extracts from the cases seen by Czermak and Tavernier conjointly, in various subjects, in whom the voice was either changed or quite suppressed, leading to the presumed existence of organic disease of the larynx.

Honorine F., twenty-two years of age, of a lymphatico-sanguine temperament, for seven years had suffered from hoarseness, and had become almost aphonic two years ago, after a masked ball, where she danced much, and drank all sorts of refreshing beverages. On leaving, the cold seized her, and from that time she lost her voice. An examination by the laryngoscope discovered an excrescence the size of a small pea lying in front of the right arytenoid cartilage. The vocal chords were slightly redder than in the normal state. This patient submitted willingly to the examination three different times, nor showed the least repugnance.

Julie B., aged thirty-two and a half years, has for ten years suffered from hoarseness; but for five years the voice has been completely broken down—a diminution which she ascribes to suppression of the menses. These two successive accidents were followed by affections of the throat, to which abscess succeeded. The laryngoscopic examination showed that the epiglottis, in this person smaller than natural and that looked as if shrivelled, was thickened, and was red and bluish in colour. At the posterior part of the larynx, Czermak and Tavernier saw a small yellowish-white mass projecting into the interior of the glottis, and this seemed to be the cause of the extinction of the voice, by hindering the approximation of the chords.

N., twenty two years of age, suffers from severe coryza, which alternates with failure of the voice, produced, she says, by the cold she suffered during an abundant fall of rain when on a journey so long that her clothes became dry ere she reached its termination. The laryngoscope exposes a marked swelling of the vocal chords, and excrescences, two millimeters in height, on the anterior part of the left arytenoid cartilages. During the second examination, two days subsequently, the mirrors exposed a patch of redness at the angle of insertion of the vocal chords, the borders of which are undulated.

Adèle L., twenty-two years of age, of a lymphatico-nervous temperament, suffers from hoarseness, which she cannot attribute to any certain cause, and has existed for two months. The examination (August 21) shows a high degree of redness, with thickening of the membrane covering the epiglottis.—August 28: Another examination. The voice is improved, and the inflammation diminishes under the treatment prescribed.—September 8: Third examination. Sensible improvement of the voice, and the redness is evidently disappearing.

Rose S., twenty six years of age, has for five years suffered from coryza, which persists throughout the year, with exacerbations in winter, when there is complete aphonia. The patient ascribes her disease to a quantity of snow falling on her chest and shoulders as she was leaving a ball. An examination shows thickening of the membrane of the inferior vocal chords, with redness and turning down of borders.

Mlle. C., thirty-two years of age, has been affected since March last with severe coryza, which she caught when travelling by rail. This patient is tormented with a violent cough, accompanied with a feeling of burning in the chest. Laryngoscopic inspection shows the inferior vocal chords to

be red and tumefied; their borders are unequal, preventing them meeting perfectly.

Marie C., twenty-four years of age, has for a fortnight suffered from coryza, brought on by exposure to cold at an open window when occupied with her toilette and covered with perspiration. The most minute examination could discover nothing beyond simple inflammation of the membrane covering the epiglottis and chords, manifested by a vivid degree of redness and some degree of thickening.

M. A., of R., affected with complete aphonia, and acute pain in the whole of the buccal, laryngeal, and pharyngeal mucous membrane, desired the attendance of M. Tavernier, who, with M. Czermak, saw him on September 4th. After learning the state and antecedents of the patient, they began an attentive examination, which disclosed the following particulars: the tongue shows patches of redness, and is denuded in different parts; the epiglottis is red and purple, thickened and corroded, showing on its upper surface especially manifest tumefaction; its edges are irregular, and the inferior border red; the arytenoid cartilages are pale, œdematous and thickened, and a large ulcer is seen on the right part of the right vocal chord.

HOSPITAL REPORTS.

MIDDLESEX HOSPITAL.—Oct. 3rd.

Ectropion.—Mr Henry. Abdominal Fistula through Tendon of External Oblique Muscle, Cauterised.—Mr Moore.

Ectropion.

The inversion of the lower eyelid of the left eye in this case occurred to a young man, in infancy, or as far back as he can recollect, from a scald. The injury had induced a complicated condition of the parts: first, contraction of the tarsal cartilage; relaxation and thickening of the conjunctival reflection, after its leaving the lid to cover the globe; and, apparently, the action of the orbicularis palpebrarum had become abnormal. Mr Henry, to obviate these conditions, slit the lid at each angle, and removed a portion of the reflected skin of the lower lid over its whole extent, as well as a portion of the orbicularis muscle.

Abdominal Fistula.

This patient, a female about thirty-five years of age, had been for a long period a great sufferer, and in a miserable and deplorable condition; an abdominal fistula having formed after the discharge of an abscess, communicating externally through the tendons of the external oblique muscle with the cæcum coli internally. Her evacuations passed by this fistula, causing great discomfort from the disgusting state to which she was in consequence reduced. Many means had been resorted to at different times, and in different hospitals—amongst others, the application of pins and ligature had been used—but without success. Mr Moore considered this a fair case for the use of the actual cautery. To obviate the objection to hot wire so soon becoming cold, Mr Moore used galvanic heat. The wire, connected with a galvanic battery, was armed with a portion of platina wire at its distal extremity. This was speedily brought to a white heat, and introduced freely and deeply into the fistulous opening. When it lost its intensity of heat, it became speedily restored by renewing its junctions with the battery. The wire thus heated was applied three or four times. This mode of cauterisation had been resorted to on a former occasion upon this patient, and with considerable success, the fistula having in consequence become much contracted. Mr Moore was sanguine that this mode would ultimately succeed in obliterating the fistula, and so effect a cure. The patient refused the aid of chloroform, and did not appear to suffer much pain.

UNIVERSITY COLLEGE HOSPITAL.

Oct. 3rd—10th.

Amputation of Breast—Tumour on Palm of Hand—Inter-pelvic Abscess.—Mr Erichsen.

This tumour was of carcinomatous character. Infiltration of cancerous juice had taken place, superior to the nipple. Mr Erichsen said, "In these cases the whole mammary gland should be always removed." Mr Erichsen made an incision in a longitudinal or perpendicular line, contrary to the usual horizontal section or line parallel to the fibres of great pectoral muscle. He removed the nipple and all infiltrated parts. The tumour included the mammary gland. It was necessary in these cases to remove the whole mammary gland, or the infiltration would reach every or any distant part of it. The integuments over where the disease existed were dense and firm, and drawn flat, and the nipple also retracted. There was no mobility or freedom in the tissues. These conditions generally occur, as in this instance, at the period of life when the function of the uterus becomes passive, and mammary sympathy becomes more strongly developed.

Tumour on Palm of Hand.

This was a large, globe-shaped tumour, seated in the middle of palm of hand of a young man. It was of very doubtful character. Mr Erichsen had, by way of exploration, punctured it. A large quantity of blood followed: so much escaped, that pressure was required. When removed, it was found to be encysted, with all the characters of a ganglion. Mr Erichsen remarked that ganglions usually formed a sheath of tendons—ligaments to fasciæ.

Inter-pelvic Abscess.

This was a case of some obscurity, as these cases generally are. The patient, a young man about nineteen years of age, had been suffering from inter-pelvic disease for a length of time. It seemed to be seated in the iliac fossa of the right side. He could not, without great suffering, extend the leg. The leg was fixed at an acute angle upon the thigh. The disease arose spontaneously. The patient had been in hospital some time, and seemed an unfavourable subject. Mr Erichsen took the opportunity to dilate upon inter-pelvic, and inter-abdominal, and thoracic abscesses. He explained their origin, seat, and tendency. He also gave very interesting and, no doubt, accurate diagnoses of these obscure diseases. He also adverted to the source and probable conditions of disease which gave rise to these inter-pelvic formations of pus. They found their way and got below Poupart's ligament, towards the inner aspect of the thigh. The pus is not connected with the lymphatic glands. Buboes form a superficial abscess. You may get subserous peritoneal infiltration, and intro-pelvic seated upon the iliac fascia, similar to what you find occurs in the axilla from poisonous absorptions. Iliac pelvic abscesses point through the anterior abdominal wall just above Poupart's ligament into Scarpa's triangle, half-an-inch above Poupart's ligament. Those connected with ilium are to be opened above Poupart's ligament. *Pericæcal* abscess slowly forms its way into iliac fossa. Peritoneal infiltration induces intestinal disturbance and derangement. Perinephritic abscess develops itself, and forms into the iliac fossa. Besides periphrenitic abscess, an abscess may perforate the pleura, pass behind the diaphragm posterior to the intestine, and point in the iliac fossa. There are several forms of abscess in the iliac fossa. Simple psoas abscess infiltrates sheath of psoas muscle, forms a cyst, and points below iliac fossa, as discovered by Mr Saunders. The effect of psoas abscess is to draw up the leg, and draw down the body—which are in short, the same thing. This motion depends entirely upon the position in which the patient is placed. They have a limp in true psoas abscess. These symptoms were not present in this case, therefore it was not true psoas abscess. It was not caries of spine, the pus getting into sheath of psoas abscess, inducing great irritation. There was no tenderness of spine, which attends this second form of spinal disease. This was disease of pelvic bones. They are liable to disease, but not to caries. These bones have no cancelli. The disease is necrosis; but, perhaps, nevertheless, both may exist. If necrosis, it may be confined to parts posterior to pelvic bones, near the iliac fossa. They are very slow to suppurate; very little discharge will occur from the part. But if the acetabulum be diseased, we shall get hip-joint disease. All these we have named, with hip-joint disease, and also of the acetabulum, may occur in the left iliac fossa, except the pericæcal. In this case it was two inches below pericæcal abscess. Pericæcal abscess forms two inches below anterior superior spine of ileum. Mr Erichsen said the interpelvic abscess or swelling occupied middle fourth of the abdomen, and got below Poupart's ligament. A horizontal section was made, about two or three inches in extent, and in a line beneath superior spine of ileum. Upon discharging its contents, a vulcanised india-rubber tube was introduced, to be kept in the wound.

GENERAL CORRESPONDENCE.

MR BROWN'S OPERATIONS FOR VESICO-VAGINAL FISTULA.

To the Editor of the Medical Circular.

Sir,—In a late number of your Journal, you published an extract from a paper by Dr Eben Watson, in which that gentleman made a most unfair attempt, as it seems to me, to depreciate the success of Mr Baker Brown's operations for the cure of vesico-vaginal fistula. As the conclusions of Dr E. Watson were preceded by a most inaccurate statement of facts, it is but just to Mr Brown that the truth should be published in the Medical Circular. That your readers may have a clear view of the question, I will first recite Dr Watson's statement, and then append, in answer to it, a plain and simple record of the facts.

The following is Dr E. Watson's statement, as contained in the article referred to, bearing date June 23, 1860:

"5. *Amount of Success.*—Mr Baker Brown, in the paper to which I have already alluded, states that he has had 'a greater amount of success in operating for vesico-vaginal fistula than that yet published by any other surgeon.' Now, he certainly has a great number of cases of that lesion under his care, and, therefore, it may not be uninteresting to inquire into the proportion of cures to failures among them. I think we are entitled to do this, since Mr Baker Brown has boasted in the above terms of his great success, and also because Mr Baker Brown has devoted his special attention to the diseases of women requiring surgical operations. To his writings, therefore, surgeons naturally look for encouragement or discouragement in the performance of operations within the domain of his speciality. I have not been able to discover the records of all Mr Baker Brown's twenty-seven cases, but I have read his own reports of nineteen cases in the following repositories, where they may be consulted by any one:—1st. In Mr Baker Brown's book 'On some Diseases of Women,' four cases are recorded, at pp. 100 to 110. 2nd. In the 'British Medical Journal,' No. 118, four cases are recorded, at pp. 267 to 269. 3rd. In the 'Medical Times and Gazette,' No. 407, three cases are recorded, at p. 398. 4th. In the 'Lancet,' No. 13, p. 322, one case is recorded; and in No. 24, p. 581, seven cases are recorded. I think that these nineteen cases, taken just as I could find them, will exhibit the success of his practice sufficiently, without my undergoing the labour of any further search for his cases.

"Now, of these nineteen patients, two died; one apparently of pyæmia ('Treatise,' p. 108), the other of frequent hæmorrhages ('Lancet,' No. 24, p. 583); in other two cases ('Treatise,' pp. 104 and 110) the fistulæ remained open: so that four out of the nineteen cases may be considered as ultimately failures. Still, it will be said, there were fifteen cases ultimately cured; and this is a great amount of success in dealing with what Mr Baker Brown rather oddly terms 'a difficult lesion.' But this is hardly the way to look at the matter. It is not that there were nineteen operations, and fifteen of these successful. Far from it; for in many cases the operation was frequently repeated before the cure was ultimately arrived at. In one case, for instance, the poor woman was operated on twenty-five times before the fistula was closed ('British Medical Journal,' No. 118, p. 267); and, while we admire the courage of the patient, it must be admitted that the operator failed twenty-four times in this one case; yet it counts simply as a cure in Mr Baker Brown's statement of his great success. It may, indeed, be enough for philanthropic purposes to look at the number of ultimate cures; but, certainly, in trying to ascertain or to demonstrate the successfulness of an operation, we must compare the number of times it has been successfully performed with the number of times in which, when

performed, it has failed to accomplish the intended result. Now, in this latter point of view, the statistics are as follows: In the nineteen cases above referred to, Mr Baker Brown operated seventy-one times, and succeeded fifteen times—in other words, he was successful fifteen times, and failed fifty-six times.

"This 'amount of success' hardly warrants his boast, in my opinion, and perhaps does not give very much support to the cause of specialities."

Now, Sir, for that plain and truthful statement of the facts which is the answer to the foregoing specimen of special pleading.

In his work on 'Surgical Diseases of Women,' Mr Brown records *four* cases of vesico-vaginal fistula, to illustrate its nature and the difficulties of its cure. Two of these cases (28 and 29, pp. 104 and 106) were successfully treated as far as the lesion itself was concerned, but one of them subsequently died of pyæmia. The other two cases (27 and 30, pp. 100 and 108) were unsuccessful up to the period of the publication of the work, but have since been cured, and published (Case 27 in the 'British Medical Journal,' April 2, 1859, and Case 30 in the same journal, December 18, 1858). In a paper which Mr Brown read before the British Medical Association at Edinburgh, in July, 1858, he related *eleven* cases successfully treated, principally by Bozeman's plan. This paper was afterwards published as a separate pamphlet, and forwarded to every member of the Association.

Two more cases were published, under the heading of St Mary's Hospital Reports, in the 'British Medical Journal' for November 6, 1858; and in the number of the same journal for the following week (November 13) *two* more cases were recorded.

One case is published in the same journal for December 18, 1858, and *four* cases in the number for April 2, 1859.

In the 'Lancet' for December 10, 1859, seven more cases are related, six of which were cured and one died; thus making the total number of cases published *twenty-nine*, of which *twenty-eight* were perfectly cured, although one of them, as above stated, died of pyæmia.

I am, Sir, &c.,

A Lover of Truth.

IRIDECTOMY IN GLAUCOMA.

Letter from Mr Lawrence.

[The opinion of Mr Lawrence on the subject of Iridectomy in Glaucoma would be considered valuable if it could be obtained; we have, therefore, reproduced the following letter from the 'Medical Times and Gazette, as giving us the nearest approach to it. It is satisfactory to know that these cases are progressing favourably.—Ed. Med. Circular.]

Sir,—I am indebted to the polite kindness of Mr Bowman for the opportunity of examining two of his private patients, in whom iridectomy has been performed with complete success. These cases illustrate so clearly the kind of disease most suitable for the operation, and the period of the affection at which it can be performed with the best prospect of success, that your readers will be gratified by finding that Mr Bowman, at my request, has consented to their publication.

Case 1.—In Mr S., a healthy person, of spare habits, past sixty, the sight of the right eye was entirely lost eight years ago, from glaucomatous inflammation. In December, 1858, he suffered an acute attack in the left eye, with agonising pain, sudden and almost total loss of sight. He was unable to see his own fingers; he told me, indeed, that, from the intolerable pain, and the imperfection of the sense, he could not distinguish between light and darkness. Mr Bowman excised a portion of iris on the third day of the attack. He can now read a very small type (No. 2 of Jaeger's pearl) without convex glasses.

Case 2.—Mr J., a gentleman of good constitution and health, between fifty and sixty, accustomed through life to much use of the eyes in reading and writing, has had acute glaucoma, first of the right, and subsequently of the left eye. On the 28th of last July he was unable to count his own fingers, or see at all in front or to the left side with the right eye, from acute glaucoma, which had then existed one week. Iridectomy was at once performed, and all other treatment abandoned. He steadily improved, and can now read with his old convex glasses a small type (No. 3 of Jaeger's test). The visual field has extended over the central region, but he has not regained any sight on the extreme left of that eye, as Mr Bowman told him would be the case, the operation having been delayed till too much damage had been done. The sight, however, of this eye is still improving. On the 11th of the present month he came to London with the left eye more acutely inflamed from glaucoma than the other had been, but it had only been so for forty-eight hours. He could barely see that there was an object before him, but could not tell what it was. He can now (Tuesday) see No. 9 of Jaeger, on Saturday only No. 14, and he sees over the whole field. Mr Bowman has no doubt that this eye will recover perfect sight.

The inferences from these very interesting cases are so clear, that remarks would be superfluous.

I am, &c., William Lawrence.

Whitehall place, October 24.

MEDICAL SOCIETIES.

MEDICAL SOCIETY OF LONDON.

Monday, October 22nd, 1860.

Peter Marshall Esq., Vice-President, in the Chair.

Mr Baker Brown read a paper on

THREE CASES OF OVARIAN DROPSY CURED BY TAPPING AND PRESSURE.

Case I.—Mrs C., æt. thirty-six, married, admitted into the London Surgical Home July 21st, 1859—was sent to Mr Brown by Dr Jackson, of Sheffield, who kindly supplied him with the following history:

"During the last eight or nine years she had been constantly subject to severe dyspepsia, with painful and irregular menstruation, and at the catamenial periods to considerable enlargement of the abdomen. Had been married ten or twelve years; never been pregnant. About three years ago, observed a swelling, attended with severe pain, in the lower part of the abdomen, on the left side; the tumour gradually enlarged up to the period when she saw Mr Brown.

"Diuretics and resolvents had been administered for many months without the slightest relief."

On Examination, Mr Brown found a distinctly fluctuating tumour on the left side, evidently ovarian and unilocular.

August 1.—Tapped her on the semilunar line, and between three and four pints of sero-sanguineous fluid escaped. Pads and flannel bandages were firmly applied. This was kept up for a month, when she returned home.

Mr Brown saw her three months afterwards at Sheffield, with Dr Jackson and Mr Pearson, when he found her perfectly well, and upon examination could distinctly feel the puckered-up cyst in the left iliac fossa.

October, 1860.—Dr Jackson has lately written to Mr Brown to state that she is perfectly well, without any return whatever of the disease.

Case II.—E. S., æt. twenty-one, single, admitted into the London Surgical Home July 23rd, 1859.

History.—Had been ill three years, when she first perceived a swelling in the left side, which gradually increased.

On Examination, a unilocular ovarian cyst was diagnosed.

August 4.—She was tapped on the left side in the semilunar line. Nine and a half pints of pale, thin, and slightly albuminous fluid were drawn off immediately; bran-pads were applied, and firmly secured by nine yards of flannel bandage.

October 4.—Pressure had been steadily continued up to this period, when the most careful examination could detect no fluctuation. From this time she steadily improved in health, and continued as a nurse in the Institution for nine months. She is now in service, and perfectly well.

Case III.—S. D., æt. twenty-six, single, residing in the country, admitted into the London Surgical Home October, 7, 1859.

History.—Has been ill for seven years. Catamenia always regular; the abdomen generally began to fill, and for the last six months it has rapidly increased. She has never suffered much inconvenience beyond the weight, her general health being good.

On Examination, a unilocular ovarian cyst was diagnosed.

October 22.—She was tapped whilst in the horizontal posture on the left side, and thirty-two pints of a pale, thin, and slightly albuminous fluid were evacuated. Immediately very firm pressure was made with pads and flannel bandages. She complained a little of the pressure for the first twenty-four hours, but afterwards got accustomed to it. This was kept up for one month, when one of Mr Brown's ovarian bandages was applied. She returned to the country quite well, and has continued so up to the present time.

Practical Remarks.—These two cases were considered fit for the trial of this simple mode of treatment, which Mr Brown first advocated as far back as 1844. Time and experience have satisfied him, that such cases as these three now detailed ought always to be so treated in the first instance; that the padding and pressure require very careful application, and when applied *can* produce no ill effects; and that, therefore, objections on this score must arise from ignorance of the mode of application.

In reply, Mr Brown stated that he believed that some gentleman who had not brain enough to understand the application of the bandage, had stated that Mr Brown used very heavy pressure, such as Post-office Directories; but he need not say that there was an exaggeration. Mr Brown had, indeed, in his earlier cases, *once* used a small book, when he required pressure on a particular part, the same as all accoucheurs frequently do—*e. g.*, in post-partum hæmorrhage; but subsequent experience had taught him that bran-pads, made according as circumstances required, carefully applied and bandaged, answered all purposes, and produced a perfectly even pressure without pain.

Many gentlemen had since successfully applied this treatment, especially Dr Tanner, who had recorded some cases of cure; but that gentleman had made no mention of any pain or inconvenience caused to the patient by the application of the bandage. Mr Brown therefore thought that the strongly-worded statements made by others, as to the tortures to the patient and the cruelty of the application, were without fact, and only arose from ignorance of the method of application.

As regards recurrence of the disease, although in the cases Mr Brown had just read they had only been operated on a year ago, still he had had many which had stood the test of a much longer time with an equally beneficial result. Mr Brown mentioned the case of a lady who, when operated on, was single, but had since married, and been confined of three children by Mr Brown himself.

Again, as a *substitution* for ovariotomy, Mr Brown could not recommend it, *except* in unilocular cases, the proportion of which to multilocular is exceedingly small. In the latter, when they fail to yield to the injection of iodine and other methods recommended, and when death is staring the patient in the face, Mr Brown saw no alternative but ovariotomy. This operation was still undergoing a trial; but he considered it as successful as most other capital operations, and perfectly justifiable.

Mr De Meric would ask Mr Brown, if by pressure the cyst be not obliterated. This seems to be the intention, since they do not refill. He considered pressure, well graduated and calculated, would do immense good, if no excitement was produced on the confines. Three gentlemen from the Continent, here on a visit, were anxious for and applied to him to have correct information. If Mr Brown can establish his practice, he will have done good service to the Profession.

TUMOUR ON THE THIGH.

Mr Bryant brought before the notice of the Society a pedunculated tumour which he had removed by simple torsion from a woman aged thirty-eight. It was congenital, and had grown to a large size, being seven inches in diameter before removal. It was situated on the outer side of the thigh, and was of fibro-cellular structure. It fell off in seven days. The plan by which it was removed was a very simple one, and which he had accidentally discovered three years ago when manipulating a pedunculated tumour of the thigh in a young woman. When under examination, the tumour was accidentally twisted in its axis, and immediately became much congested. Taking the hint, the tumour and pedicle were fixed in this position by strapping, and in less than a week the growth sloughed off. Mr Bryant has adopted this practice in half-a-dozen instances with like success, and strongly advises the repetition in similar instances, when the patient refuses to permit the more surgical and cleanly

operation of excision. The subject was alluded to by Mr Fergusson at a meeting of the Pathological Society during the last session; but it appears that the practice had been known and carried out for several years by Mr Bryant in many instances.

The CHAIRMAN stated that he had seen Mr Liston operate on a tumour in the palm of hand in a similar way. It was of fibro-cellular character, and of a fatty nature. He also alluded to another case.—(The Clinical Discussion will be given next week.)

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, OCT. 16TH, 1860.

MR FERGUSSON, PRESIDENT.

The business of the evening was opened by Mr FERGUSSON, by some introductory remarks. He alluded to the progress of the Society during the past year; to the excellent volume of Transactions which appeared for the first time to-day; and to the subject of the proposed amalgamation of the principal medical societies of London.

The minutes of the last meeting were read and confirmed.

LUNG FROM A MILLSTONE-MAKER.

Dr PEACOCK exhibited the lung, and some very fine microscopical preparations and drawings illustrating the morbid condition resulting to the lung from the occupation in question. A large quantity of silicious material was found in the substance of the lung itself. The fact had been denied that such matter could reach the lung; but here was a positive illustration of its occurrence.

Dr PEACOCK also exhibited a

DISEASED HEART.

The symptoms of the case were detailed at some length, and compared with the morbid specimen. This, as well as the previous subject, was illustrated by some very beautiful drawings by Mr Tuffen West.

An interesting conversation took place, in which Dr Williams, the President, Dr Leared, and Dr R. Bennett took part, in reference to the specimen of the millstone-maker's lung.

Dr MURCHISON presented a specimen of

PRIMARY CANCER OF THE PERITONEUM.

No other organ was similarly diseased. This specimen was interesting in relation to the subject of gastro-colic fistula, and to Dr Murchison's previous researches thereon. There was a cancerous tumour in the omentum, connecting the stomach to the transverse colon.

KIDNEY WITH LARGE CYST ATTACHED.

Dr MURCHISON exhibited a remarkable specimen of thia disease—a cyst attached to the outside of the kidney by a very narrow pedicle. The cyst was as large as the kidney itself. The contents of the cyst were not of a urinary nature.

Mr SEDGWICK exhibited a coloured drawing of

A CASE OF TRUE KELOID.

The patient was a girl, aged four years and a half, of a strumous diathesis; and the first patch of the disease had appeared on the back about two years ago. Since then thirteen other patches had been developed at short intervals, of which the first seven were limited to the back; one occurred on the right lower eyelid; one on the skin of the right ear, near the external meatus; one occupied nearly the whole of the right margin of the tongue; and the others were on the front of the body and the neck. The patient had had the tendons of the left foot divided in six places for talipes equinus; but the cicatrices were quite free from any appearance of the keloid, nor was it associated with burns, scalds, or local injury. A treatment by cod-liver oil, quinine, and liberal diet, had for the present apparently checked the progress of the disease.

Mr SEDGWICK also exhibited a coloured drawing of

A CASE OF ITCHTHYOSIS,

in a boy aged fourteen years. The disease had been hereditary in the family for three generations, and was limited to the males by transmission through the females, who themselves remained free from it. It had first shown itself in the grandfather, and after skipping the second generation, consisting of three sons and three daughters, had reappeared in four of the grandsons by the female line of descent.

Mr T. HOLMES showed a specimen of

FRACTURE OF LOWER JAW,

in which the injury was associated with sero-sanguineous discharge from the ear of the same side.

Mr Wells, Mr Toynbee, and others took part in a discussion on these sero-sanguineous discharges.

Mr TOYNBEE exhibited a specimen of

MOLLUSCOUS TUMOUR OF THE EAR,

which was interesting on account of its connection with disease of the brain—an abscess in the cerebellum.

Mr ADAMS showed a specimen of

TUMOUR OF THE LOWER JAW,

which he had removed from a middle-aged man. A report will be furnished on this specimen.

Mr DURHAM exhibited a specimen of

HORNS FROM THE HUMAN SUBJECT.

One of them was removed last week by Mr Cock, and was the product of twenty-five years' growth. Mr Durham also produced several interesting specimens of similar growths from the museum of Guy's Hospital, and illustrated the subject at some length.

Mr S. WELLS showed a specimen of

OVARIAN CYST,

which he had removed that morning from a lady, aged fifty-three. It was multilocular, consisting of one very large cyst (which had contained between forty and fifty pints of fluid), and of a number of groups of smaller cysts, growing in and from the walls of the principal cyst, and weighing about eight pounds. The existence of these smaller cysts had led him not to inject iodine when he tapped the patient the first time, six months ago. They had grown rapidly since the tapping, although the large cyst had filled slowly. The parietal adhesions were very firm; but the whole of the tumour had been withdrawn through an incision hardly four inches long. The patient was going on well. In reply to a question from the President, Mr Wells stated that the peduncle was long, and easily fixed outside the wound in the abdominal parietes. The clamp was used to secure the peduncle until the cyst was removed and the wound closed; but it was taken away as soon as a ligature had been applied. The clamp was only of temporary utility. If left on, it was uncomfortable to the patient, and caused unnecessary dragging upon the peduncle and uterus.

OUR NOTE BOOK.

DELIVERY OF THE PLACENTA IN ABORTION IN EARLY PREGNANCY.

In the 'Lancet and Observer' for July, Dr L. D. Sheets has an article upon the above subject. It is a generally-acknowledged fact that most of the alarming cases of hæmorrhage accompanying abortion are caused by a partially-detached placenta. In such cases the complete detachment and removal of the same constitutes the appropriate treatment. The important inquiry is, how can this best be done? But to the paper. In regard to diagnosis, Dr Sheets says, "We make out the diagnosis by the touch, as we can often, without any extra effort, feel part of the after-birth at the internal os; but if this examination prove unsatisfactory—if we feel nothing—we must introduce the finger still further, until we can traverse the whole internal surface of the womb, and in perhaps every case we will find a placenta." This may be a feat of easy performance, but we have seen cases in which we could not perform it, and we have the satisfaction of knowing that some of our ablest and most experienced obstetricians have been placed in the same unfortunate condition. Hence, it may be well for the young practitioner to be prepared for a failure in this regard, and it may not be amiss to be acquainted with other resources.

We give Dr Sheets' method of removing the placenta in these cases, which removal is really the object ever to be had in view. "My method is to remove the placenta with the index-finger, on which I always keep a tolerably long nail, for the purpose of separating the after-birth from the womb. The nail should not be too long, or it will not be sufficiently firm, and may bend backward while using it. Push the uterus as low down in the pelvis as possible, and retain it there with the left hand, while you introduce the index finger of the right hand into its cavity, and pull off the placenta, and remove it. Sometimes it is a little difficult to separate with a single finger, and I do not get quite all removed; but it is so much broken up as to arrest the violence of the hæmorrhage, and render the tampon, &c., unnecessary; in a few days the remainder will come away piecemeal."

So it seems that Dr Sheets is not always quite successful in the removal. We have a horror of "piecemeals," and believe that success may always crown our efforts. Because of the vast importance of the subject, our readers will pardon a few comments, if even a little critical. Dr Sheets may always by this means arrest the hæmorrhage, but we know that we cannot, and we fear there may be some that might be alike unfortunate, and hence, for us, there must be found another and easier road to success.

We have seen several cases in which it was all we could do, with justifiable force, to touch the os, saying nothing of "traversing the whole interior of the womb."

Prof. Meigs is free to confess that there are a good many cases of "abortion in the early stages," in which he has failed to extract the placenta. Of this acknowledgment Dr Sheets says, "How remarkable that the corypheus of obstetricians in this country should fail in what can be performed in every instance!"

Has he forgotten that he sometimes succeeded only in part? When Dr Sheets has seen, as we have, a girl of fourteen years, about at two and a half months, with a vagina undisturbed by previous childbearing, and, because of youth, at best but imperfectly developed, and the os uteri only just within reach, he may find a case of failure, unless he has a very small hand, or has a finger-nail two inches in length. Ramsbotham and others have called attention to the fact that there are some cases in which the hand cannot be introduced into the vagina. Dr Sheets thinks it strange that it should not occur to so sagacious authors that if the hand cannot, the finger can. We repeat that we have had cases in which the finger was not long enough. We suppose that others may be as unfortunate. Dr Sheets says, "On account of having short fingers, I am often obliged to introduce my hand into the vagina: but I always reach the fundus of the womb without difficulty." We repeat, there are cases where a physician would not be justified in using the requisite force for the introduction of an ordinary-sized hand, at least so long as there is a better, easier, more expeditious, and less painful way to accomplish the same end. Bearing upon this point, we quote, with pleasure, from Dr A. K. Gardner, of New York. He says, "How shall the small and fragile placenta be seized hold of and withdrawn? Some have recommended the introduction of one finger into the uterus, and bringing down one edge of the placenta, and twisting it round and round, not only thus to detach the entire mass, but to also so shape it that it may the more easily pass through the os. Where this can be done, by all means do so! But it should be remembered that in the great mass of cases it is impossible to reach the os, so as to pass one finger into the cavity; far less to effect any good result, if it arrive there, to say nothing of the utter impossibility of aiding the finger with the thumb of the same hand." Thus it will be seen that we are not alone in finding cases in which the unaided finger is inadequate to the successful treatment.

Dr Sheets has a poor opinion of the tampon in these cases, believing it to be productive of much mischief. In this opinion we concur most heartily, but we cannot join him in the condemnation of instrumental aids in the delivery of the placenta. We have seen that, however successful Dr Sheets may be in making the unaided finger accomplish all that is desired, there are those, and we among them, who are very far from being so successful.

We have been in the habit, for some time past, of delivering the placenta, in these cases, with Carey's decidual separator, if the finger is inadequate to the end. With this the separation is easily made, the evulsion speedily accomplished, and the consequent hæmorrhage ceases at once and permanently. The irritation from the introduction of the instrument is far less than from the introduction of the hand, especially when the abortion is in a primipara, and at a stage anterior to the fourth month. Our rule is to lose no time with the trial of styptics, the tampon, &c., but to separate the placenta, and remove the secundines at once,—with the finger if we can, and with instruments if we must. At all events, effect the

removal, and the hæmorrhage ceases, and all danger is past.—'American Medical Monthly.'

[Upon the points in dispute argued in this article, we may observe that we have removed the placenta after miscarriage, on three or four occasions, in this way. Two fingers (not one)—the fore and middle fingers—have been introduced *per vaginam*; a loose portion of the placenta (which is commonly found in these cases at the os uteri, if the hæmorrhage have been so severe as to *require* manual interference) is then seized. The placenta being steadily and carefully pulled downwards, the uterus, of course, descending with it, the fore-finger of the left hand is passed in, and the placenta is seized between it and the middle finger of the right hand: the uterus being now fixed, the forefinger of the right hand can be easily passed into the uterus, and the placenta separated. The process is a simple one, and always effective in our hands, when the placenta can be thus seized. —Ed. Medical Circular.]

UTERINE NEURALGIA.

In the 'Lancet and Observer' for July, Dr E. J. Fountain reports a case of severe uterine neuralgia, which resisted the usual treatment; large and repeated doses of opium included. At this stage he says: "Recollecting an account of a case of fascial neuralgia promptly arrested by the muriate of ammonia, published in 'Braithwaite's Retrospect,' I concluded to give it a trial in this case. I ordered half a drachm to be taken every hour, until some effect should be produced. She began to feel some relief shortly after the first dose, still more after the second, and the third dose removed every vestige of pain, and she dropped into a natural and refreshing sleep, the first she had enjoyed for ten or twelve days. She continued taking the preparation for several days, three times each day, in gradually-diminishing doses, and had not the slightest return of the difficulty.—'American Medical Monthly.'

OPIUM IN PNEUMONIA.

In the report of cases of pneumonia, treated at the Charity Hospital, N. O., under the charge of Prof. Austin Flint, and by him reported for the 'New Orleans Medical News and Hospital Gazette' for July, the following language occurs in regard to the use of opium in pneumonia: "Of the value of opium in the treatment of pneumonia, my experience has furnished abundant evidence during the last five or six years; and the more my experience accumulates, the more am I satisfied that the free use of this drug will come to be regarded as a very important measure in the management of certain cases of the disease."

Our experience is in full conformity with the above, and we are happy to adduce so high an authority in support of our opinions, long since entertained and expressed. Though most authoritative writers condemn the use of opium in pneumonia, we were early induced to depart from standard authorities, and each year's experience but adds to our conviction of its propriety, and to our confidence in its utility. Our own views are given in the 'Monthly' for January last, in a notice of W. W. Gerhard's work upon 'Diseases of the Chest.'—'American Medical Monthly.'

EXTRAORDINARY PROCEEDINGS AT MARYBOROUGH DISTRICT LUNATIC ASYLUM.

On Friday, Dr Hatchell, Inspector-General of Irish Asylums, and Lieutenant-Colonel M'Kerlie, one of the Commissioners of Control, &c., of Asylums, attended at the Asylum, Maryborough, for the purpose of resuming the inquiry ordered by the Lord-Lieutenant, at the request of the Resident Physician, into certain matters connected with the internal conduct of the institution.

Dr Burton, R. P., proceeded to read his reply to evidence. He first went at great length into the assault committed on Dr Jacob, V. P., by an inmate, named Margaret Kelly, and which Dr Jacob attributed to the connivance of some parties in the asylum. This statement was most puerile, and he (Dr Burton) considered that unsubstantiated assertions were most unjust towards the institution. Dr Jacob stated that Margaret Kelly did not exhibit any symptoms of unequivocal insanity. The woman was one of the strongest he had ever seen, and the treatment she had received was such as to exasperate her towards Dr Jacob. He referred to the fact that Dr Jacob had frequently to be guarded by a band of attendants in his visit to the house, which, he thought, showed a feeling between him and the patients which should not exist. The next statement he referred to was that there was a conspiracy amongst some persons in the institution to thwart and obstruct him in the discharge of his duties. It was wholly unsubstantiated and contrary to fact, so far as he (Dr Burton) knew. A patient named Miles Tierney had been removed from the convalescent ward to another, where he received very severe treatment for repeating, as he was informed, a copy of some verses he wrote to the Valuation Commissioners on the occasion of their visiting the house. He was subjected to very severe treatment in consequence of having handed a copy of some verses to Dr Jacob himself. The statement that he had offered to back Kane to the amount of 100*l.* was untrue. The statement that he had advanced money towards the defence of Kane on the trial already alluded to was likewise untrue. Dr Jacob complained that he (Dr Burton) had no wine when called for. He could prove that he had that day given the last of the wine to a sick patient. Dr Burton next alluded to the charge brought against him of having allowed a patient, named Coulton, to go out with a gun without supervision. He reminded the commissioners that it had not been proved that Coulton had ever carried a gun in his (Dr Burton's) presence, and he had given special directions not to allow Coulton to take it in his hand. He (Dr Burton) did not, at the time he took Coulton out, look upon him as a lunatic in any light, either medically or legally. He was perfectly convalescent and perfectly trustworthy, and skilful in the use of firearms, having been in the constant habit of using them, and having a gun of his own the greater part of his life. He considered it a great indulgence to get out with him, and he (Dr Burton) considered that in all cases where a patient could be indulged without danger it should be done, as it had a beneficial effect. Dr Burton proceeded to answer the charges made against him on the last day of the investigation—Friday, the 28th ult. It had been stated then that the former matron and storekeeper had left in consequence of differences with him. The former storekeeper (Mr Vanston) was now the private agent of Dr Jacob. He had been reprimanded, and soon after he gave in his resignation. After Vanston left he brought some charges against him (Dr Burton), and after an investigation they were declared quite groundless. The previous matron resigned in consequence of ill health, and not because she could not bear his conduct. He himself had seen the present matron (Miss Farrell) profoundly affected by what she termed the brutal treatment of Dr Jacob. As to the statement that he had not visited the patients—or some of them—for months, or even weeks, he must denounce it as a most unqualified falsehood, whoever told it to Dr Jacob. After going at much length through all the matters mentioned during the course of the evidence already submitted, Dr Burton proposed that he should produce witnesses to corroborate his statements on oath.

Dr Jacob said he anticipated the course Dr Burton had taken, and he had prepared a memorandum, which he begged the commissioners would allow him to put in evidence to vindicate his character.

Dr Hatchell said Dr Jacob had at the proper time given his evidence, and had made certain statements to which it was only fair Dr Burton should have an opportunity of replying. That day was appointed for the purpose, and he could not allow Dr Jacob to interrupt the course of the inquiry. At the proper time he would be heard.

After a very lengthened investigation,

Dr Burton was affirmed, and proceeded on oath to testify to the facts he had already stated.

Dr Nugent, the senior Inspector of Lunatic Asylums, was examined at the request of the Resident Physician. He said he had been acquainted with the asylum for fourteen years in the capacity of inspector, and for ten years as a governor, and he was familiar with the working of the establishment. There were no similar institutions in Europe that equalled the Irish district asylums in the number of cures, in the paucity of deaths, and the immunity from accidents generally; and they were, at the same time, more economically worked than public asylums elsewhere. He could state—and it was, he need not add, most satisfactory to him to be able to do so—that, notwithstanding the discord and the contests that had existed in that asylum, it occupied a fair position as compared with the other district asylums of the country. It might not equal some of them in the proportionate number of cures, but its proportion of deaths was under the general average. Taking the last four or five years, the number of deaths there, it had happened, was less in proportion than in any other asylum. Accidents had occurred, and must occur, in lunatic asylums as the natural consequence of the class of persons occupying them; but still the fact was that, within a period of five years, the number of deaths resulting, not from natural causes, but from accidents and violence, was only 13 in the Irish asylums, as against 140 in another country. It was, of course, gratifying to every one connected with the asylums and with his own department to be able to refer to these distinguishing characteristics. (Hear, hear.) Then, as regarded fiscal management, he did not know of any asylum in Ireland where the governors looked more carefully after the expenditure of money; and the result was that, having regard to the population of the asylum (between 160 and 170), its cost was about the same as the average of the large and small asylums, or, perhaps, about from 10*s.* to 15*s.* per head more. Dr Nugent, in answer to questions put by Dr Burton through Dr Hatchell, said he thought the internal working of the asylum was very unsatisfactory. In no other asylum did such a state of things exist as did there in relation to the medical officers, whose disagreements embroiled everything else. In other asylums there was a better, a more give-and-take spirit amongst the medical officers; there was more cordiality and more desire to work together for the good of the asylum. The position of Dr Burton now was not such as he and his late colleague, Dr White, intended it should be when Dr Burton was appointed resident physician. The conduct of Dr Burton, so far as the inspector's office had experience of him in the discharge of his duties, was satisfactory.

Dr Nugent was very sharply, if not offensively, cross-examined by Dr Jacob with regard to the relative duties of the resident and visiting physicians, and the rules that regulated them. He was also cross-examined as to whether he imputed to Dr Jacob the making of unfounded statements. He said he did not impute to him that he ever wilfully made unfounded statements.

A number of witnesses, servants in the house, were produced by Dr Burton to prove various details of the statement he had laid before the commissioners, in contradiction of the statements of Dr Jacob.

The inquiry was resumed on Saturday morning by Dr Hatchell and Colonel M'Kerlie.

Persons employed or who had been employed in the asylum were produced by Dr Burton, the resident physician, to prove various parts of the statement he had made to the commissioners, and in support of which other witnesses had been examined on the preceding day. Some of the witnesses were examined by Doctor Burton in reference to some differences he had had with the matron of the institution; and others gave evidence as to the differences with Dr Jacob, and as to his mode of proceeding on the occasions of his visits to the asylum. Two or three of these witnesses had ceased to be connected with the asylum, and said they were unable to remain because of Dr Jacob. Dr Burton examined the witnesses for the purpose of showing that Dr Jacob's treatment of some of the keepers, and also patients, was calculated to prevent the various officials from performing their duties satisfactorily.

The Commissioners called for the head attendants, and examined them as to the directions they received from the two medical officers. It was stated that the directions often conflicted, and that the visiting physician appeared to have more authority than the resident physician.

CHARGE OF MANSLAUGHTER AGAINST MR EVAN THOMAS.

At the Birkenhead Police-court, yesterday, Evan Thomas, known in Liverpool as a "bone-setter," surrendered on a charge of the manslaughter of Francis Timlin, a child aged eight years. The circumstances of this case have already transpired through the Coroner's inquiry, conducted a short time since. The deceased, who is the son of a labourer named Patrick Timlin, it will be remembered, was submitted to the treatment of Mr Evan Thomas, for a supposed fracture of the thigh-bone; and, having subsequently died, that event was sought to be associated with Mr Thomas's treatment.

The magistrates on the bench were the Rev. Mr Coxon, and Messrs R. Bryans, B. Darbyshire, and J. B. Case. The greatest public interest was manifested in the case, the court being densely crowded throughout the day. Among the spectators were Mr J. Bramley-Moore; the Rev. Mr Howson, principal of the Collegiate Institution; Mr Frost, Mayor of Chester; Mr Booker, Mr Buchanan, and Mr Daglish, besides numerous medical gentlemen.

Mr J. B. Aspinall (instructed by Mr Clarke Aspinall) appeared for the prisoner.

From the evidence of Patrick Timlin, and other witnesses, it seemed that on Tuesday morning, the 2nd inst., the deceased child complained of pain in the knee, which he attributed to a blow inflicted by a younger brother. On

the following Friday, having in the mean time become worse, he was visited by Dr Lambert, who ordered poultices of linseed meal or bran to the part affected, and the strength to be supported by good diet, with the addition of a little wine. Poultices were applied accordingly, and continued until Saturday, when, on the suggestion of some neighbours that the boy was suffering from a fracture of the limb, he was taken to the house of Mr Evan Thomas. This gentleman, on examining the limb, pronounced it to be fractured, adding that his fee for setting the bone would be ten shillings. The patient's father having but 5s. to offer, proposed that Mr Thomas should accept that amount, assuring him that he would pay the remainder of the required sum on a second visit. Mr Thomas, however, declined the proposal, intimating that he gave "no trust." The father then took the lad away, and was about to place him in a cab for conveyance home, when the pecuniary difficulty was met by the timely arrival of a friend, who advanced the needful sum. The lad was taken back to Mr Thomas's, and that gentleman, on receiving his fee, proceeded to treat the patient for a fracture, by apparently going through the process of setting the bone, and then binding the limb with splints, &c., ordered cold applications. On Sunday the child became worse; and on Monday, Dr Lambert having again been called in, removed the bandages, asserting that there was no fracture whatever.

Dr James Lambert, Union Medical Officer for the north district of Birkenhead, in which the deceased and his parents resided, deposed to his attendance on the deceased Francis Timlin, commencing on the 5th instant. On examining the boy on his first visit, he observed the inner portion of the outside of the thigh to be red and inflamed. From the state of the pulse, the tongue, the skin, and other indications, he concluded that matter was forming in the thigh, and that there would probably be an abscess; ordered poulticing and good diet, with a little wine, and continuation of the treatment until his next visit. On the Monday following he was informed that the child was worse, and on again visiting it, much to his surprise he found the child in a sinking state. On examining the leg, he found it bound up in splints and bandages, from the knee to the top of the thigh, and observed that the limb had been treated for a fracture. He knew, however, that the limb was not broken, and expressed his surprise at the treatment to which it had been subjected. From the state of the limb, the bandaging would have a most injurious effect, by increasing the inflammatory action, and favouring the absorption of matter into the system. The effect of such absorption would be to induce the disease called pyæmia. The child was then sinking, and on Tuesday he found that it was dead. The post-mortem examination showed a considerable quantity of matter in the right thigh, infiltrated among the muscles, and round the bone. The bone, on being taken out, was entire, and not fractured. The thorax, on being opened, showed adhesions between the two pleuræ, and effusions of serum. The pericardium was almost filled with turbid serum; there were considerable depositions of lymph over the surface of the heart; in the right ventricle there were three distinct abscesses found in the substance of the organ; the kidneys were highly congested, and studded with minute depositions of matter; the brain, as well as the lungs, was congested; the other organs presented no unusual appearance; there was no phlebitis or inflammation of the venous system. Considered that pyæmia was the cause of death, produced by the absorption of matter from the thigh, the absorption being accelerated by the bandaging of the part affected.

In cross-examination, the witness stated that pyæmia was not always fatal. Would undertake to swear that pyæmia had not set in on Friday, because there were none of the symptoms of pyæmia present. The symptoms of pyæmia were a quick pulse, profuse perspiration, and general feverishness. No notice of the post-mortem was given to Mr Evan Thomas, so far as witness was aware of. Thought it quite fair for the post-mortem to have been made in his absence. Believed that death was accelerated by the pressure of the limb and the treatment to which the deceased had been subjected. Saw a prescription which he believed to have been written by Mr Thomas's son; it included quinine, which he considered was proper to give. Pyæmia, he believed, originated in absorption of matter; never knew a case of pyæmia arising from absorption of an abscess under proper treatment. Had read of some cases of the sort. In cases where there is inflammation, or where there is a doubt as to the existence of a fracture, it was not usual for medical men to place a limb in splints. It was quite improper to use splints in a case of inflammation. In cases of suspected fracture, witness saw no objection to splints, if applied loosely; but they would be injurious if applied tightly. Supposing splints were loosely applied, and the inflamed part was constantly kept wet, the inflammation might be benefited. such a mode of treatment was not the practice of Surgeons. Splints were occasionally applied by Surgeons, even where there was no fracture; but where matter was in the course of formation, cold applications would be decidedly injurious.

Dr Baylis, who was present at the post-mortem examination, agreed generally in the appearances already described, but differed from the previous witness in one or two unimportant particulars. Was of opinion that death was caused by pyæmia, and considered, from what he had observed, and the evidence he had heard, that the pyæmia was induced by improper treatment. The grounds of his opinion were, that the matter in the thigh was due to an effort of nature, which would have been assisted by poultices, but which was interfered with by the application of splints and wet bandages. The evidence he had heard confirmed him in that opinion. The witness stated that he had a similar case under his care some time ago, but the abscess was in the forearm, and, in that case, the limb had been subjected to pressure by Mr Evan Thomas.

Mr Aspinall.—You have no right to mention a case against Mr Evan Thomas; you may strengthen your own opinion by cases which have come to your own knowledge, but you have no right to prejudice the accused. It is disgraceful.

Mr C. Evans, Surgeon to the Birkenhead Hospital and Dispensary, agreed generally with the evidence of the two previous medical witnesses. Was of opinion that death was caused by pyæmia, induced by absorption of matter from the thigh; and that the absorption was accelerated by pressure.

In cross-examination the witness said that, in a case where extensive inflammation had been set up, it was possible for a qualified practitioner to be uncertain as to the existence of a fracture. In a case of diffuse inflammation, such as existed in the patient under consideration, the application of splints would be injurious. He believed that pressure on the suppurating surface increased the absorption.

Mr John Dowling, Surgeon, was present at the post-mortem, and agreed generally with the appearances detailed. From what he had seen, and from the evidence he had heard, he was of opinion that the cause of death was pyæmia, produced by the absorption of matter from the thigh, and that the application of splints was highly calculated to promote absorption. Believed that the treatment to which the child was subjected accelerated death, but could not say that it would have lived in the absence of that treatment.

This being the case for the prosecution, evidence was taken for the defence.

Hugh Owen Thomas, a qualified Surgeon, and son of the accused, with whom he practises, stated that on the child being brought to their establishment, on the 6th instant, he examined the case. Found the thigh swelled, tender to the touch, and somewhat inflamed. Considered that an injury had been sustained by the epiphysis of the bone, but could not, in the state of the limb, ascertain if there was a fracture or not. Left the case in the hands of his father, and was present while the child was operated upon. Was engaged with other patients at the time, and did not pay special attention to the case; but did not see any attempt made to set the bone. Had obtained his degree three years, and during that time had had a good deal of practice. Considered that what was done was proper to be done under the circumstances.

Patrick Timlin, the father of the deceased, in reply to the bench, denied that on the occasion of his first visit to the establishment of Mr Evan Thomas he had any conversation whatever with the last witness.

Dr O'Donnell, having heard the evidence, was of opinion that the treatment adopted towards the deceased had no influence in inducing death. Pyæmia was a disease of the blood; and probably when the symptoms appeared the boy's lungs and pericardium were diseased at the same time. From all that he had heard, he was of opinion that pyæmia was in the child's system when first seen by Dr Lambert, and that it must have died under any circumstances.

Dr Roberts, brother-in-law to the accused, having heard the whole of the medical evidence, doubted very much whether the treatment of Mr Evan Thomas had anything to do with accelerating the child's death. In support of his opinion, the witness detailed his experiences of one or two cases in point. Believed it probable that exposure to cold by conveyance across the river hastened the disease. In cases where there was a doubt as to fracture, it was quite proper to employ splints; but it was often difficult to tell whether matter had formed.

Mr Pope, Surgeon, formerly of the Southern Hospital, was of opinion that the treatment pursued by Mr Evan Thomas was not instrumental in inducing death. Had seen a case of pyæmia, from a similar cause, result in death, without any pressure being applied.

Dr Lodge was of opinion that there must be a diseased condition of the blood to produce pyæmia, and therefore considered that it would be extremely difficult to say that pyæmia was produced by pressure in the case under consideration.

Mr Aspinall, in addressing the bench on behalf of the accused, contended that the treatment pursued by Mr Evan Thomas was consistent with the practice of medical men; and that, even supposing it were not, an error in judgment, to which all medical men were liable, could not involve the crime of manslaughter. He attributed the prosecution to the envy and uncharitableness of those medical gentlemen who were jealous of Mr Evan Thomas.

The magistrates, after retiring for a short period, decided on committing the prisoner for trial. Bail was renewed.

THE CHINESE EXPEDITION.

The Special Correspondent of the 'Indian Lancet,' writing from Talien Hwan Bay, 10th June, 1860, says:

"On the 19th of May, the 1st Division of the expeditionary force left Hong Kong, *en route* to the rendezvous at Talien Hwan Bay, on the northern shore of the Yellow Sea, and in the same degree of latitude as Pekin. Our embarkation took place under most unfavourable circumstances. One of those sudden storms of heavy rain, for which tropical regions are celebrated, burst on our devoted heads the morning we were ordered to embark. The usual preliminary instructions for the baggage to be conveyed to a place convenient for transport to the boats, and for the men to parade, had been given out, from that exquisite miniature of the red-tape and sealing-wax office, the orderly-room. The rain, however, continued with unabated violence, and reason, in the corporeal form of the senior Medical Officer, for once got the ascendency—the orders were countermanded, and the men, for that night, slept on dry bedding. This was too good a joke to be perpetrated more than once, and next morning routine carried the day: wet or dry, the men must be got on board. Wet they embarked, and wet they remained, without a prospect (for many days) of getting dry. The consequences might have been foreseen by any one gifted with a very ordinary share of common sense. Fevers, catarrhs, and diarrhœa prevailed to such an extent, that the majority of the men on board were rendered unfit for duty during the first week, and many have not yet recovered. Fever, in this country, is easily contracted, but very difficult to shake off. It very frequently passes from the common continued to the typhoid form, which leaves its victims miserable wrecks of their former selves. Diarrhœa yields very slowly to treatment, and when it becomes chronic, is a most formidable disease. It occurs frequently as a sequel of fever, and is then very difficult to control. Fortunately we had no fatal cases during the voyage; but several of our strongest men have been so much reduced by disease, that they cannot possibly be of any use, in active operations, for some time. Another cause of sickness, and one even more reprehensible, existed, and had it not been at once removed, would have been attended with the most serious results. I allude to the salt pork provided by the Commissariat at Hong Kong for the use of the troops during the voyage. All the available pork

in the merchants' stores at Victoria was bought up and shipped for this especial purpose, in order that the Commissariat stores might remain intact for future use. There was no brand on the casks containing this pork to shew the date of its preparation, as that would have betrayed a commercial secret, and gone far to render it unsaleable. The moment the head of a cask was started, sulphuretted hydrogen was evolved in such quantity, that it was impossible to approach it. One of them was completely opened, and it was found to contain nothing but a mass of black and putrid filth. As a matter of course, it was instantly thrown overboard. Several casks contained what might be called a superior quality of pork. The flavour was not quite so high, but when cooked, the muscular parts displayed a tint of dark green, gradually deepening to jet, not usually met in wholesome food. I have no doubt, the gentlemen of the Commissariat had a very arduous task to perform, when they were called upon to purvey for so large a force, in a country where salted food is seldom prepared. But they have no right to hazard the success of an expedition like the present, by issuing supplies that a dog would not touch, especially when they have the means of ascertaining (by boards of survey, &c.) that these supplies are, at least, sound in condition. This applies more particularly to provisions intended for use at sea, where frequently no substitute can be found. That this most essential duty was either neglected, or performed in a very careless manner, one glance at the *outside* of a barrel of pork such as we had on board would abundantly prove. Fortunately the salt-meat ration was not confined to pork, as a proportion of beef was included in the supplies for the voyage. Thus, the men were saved from a bread-and-water diet, one that certainly would not add to their efficiency in the field.

"June 20th.—Nearly thirty transports have now arrived with troops; and on reference to them, I find that the majority urge the same complaint against the Commissariat supplies above allnded to, so that my grievance is not an exceptional one.

"Since we reached these northern latitudes, I have remarked a wonderful tendency towards hybernation amongst the arrivals from India. Instead of making a virtue of necessity, as you good people in India do, by rising early, because you cannot remain comfortably a-bed, we denizens of the north find it difficult to tear ourselves away from the warm blanket, with the mercury standing at 60° Fahr. It is a fine, bracing temperature, and contributes much to the maintenance of health and the recovery of the sick. The first step, on our arrival here, was to land a party, under an armed guard, to sink wells for the supply of water to the fleet. There are plenty of small springs all along the coasts, and excellent water can be had in any quantity at a depth of five or six feet. Our chief difficulty is, the non-existence of fresh provisions. The villagers around the Bay have driven all their cattle inland, beyond the mountain range that forms a kind of landward barrier, and they cannot be induced to bring supplies, even at the sight of the mighty dollar. The supply of live stock in most of the transports is exhausted, and nearly every one luxuriates on salt provisions.

"We have just heard of Lord Elgin's arrival at Hong-Kong, and now we hope that our future movements will soon be determined.

"You will be glad to hear that the subscription to the 'Alexander Testimonial' progresses most favourably amongst the Medical members of the Chinese expedition."

A NEW FEEDING-BOTTLE AND SHIELD.

We have been favoured by Messrs Morgan Brothers with a view of two new inventions, which, we hope, will be as successful as they are neat and ingenious. The one is a feeding-bottle, supplied with an elastic tube and perforated teat; and the other is a nipple-shield, with a similar tube and teat. The latter, we have been informed, has been tried with success. Perfect appliances of this kind are desiderata in the nursery.

DEATHS.

PARSLEY.—October 19, at Woodborough, Somersetshire, Samuel Parsley, formerly of Worle, Somersetshire, aged 82.

TRESTRAIL.—August 1, at Bathurst, West Coast of Africa, of yellow fever, only nine days after his arrival, William Mitchell Trestrail, Staff-Assistant Surgeon in the Army, aged 28.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen having undergone the necessary examinations, received their diplomas in Dental Surgery at a meeting of the Board on the 24th inst.:—Francis Hancock Balkwill, Canonbury, Islington; James Kempe Devonshire, Great Coram street; John Evans, Gloucester cottage, Upper Albany street, Regent's park; John Spencer Fitkin, Fleet street; St George Freeman, Waterford; George Fellows Harrington, Ryde, Isle of Wight; Samuel George Leigh, Leeds; Martin Magor, Penzance, Cornwall; Joseph Lewthwaite Ritson, Carlisle; William Ryding, Limerick; William Williamson, Elgin, N.B.

APOTHECARIES' HALL.—Names of Gentlemen who passed their examination in the science and practice of Medicine, and received certificates to practise, on Thursday, October 18th, 1860:—Frederic Charles Bailey, Norwich; William James Lancaster, Barnsley, Yorkshire; Thomas William Onwin, Birmingham; William James Thomason, R.N.; Frederic Hase Watts. The following gentleman also on the same day passed his first examination:—James Savage, Hull School of Medicine.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—Robert Uvedale West, M.D., L.R.C.P., and L.R.C.S., Alford, Lincolnshire, was elected a Fellow of this College on the 17th inst.

APPOINTMENTS.—Dr R. Wollaston has been elected Physician to the South Staffordshire Hospital, in place of Dr Topham, resigned; Mr C. W. Browne has been appointed Resident Medical Officer of the Metropolitan Hospital, Devonshire square; Dr T. A. Carter, of Leamington, was elected Honorary Physician to the Warwick Dispensary on the 17th ult., *vice* Dr Allanby, who has recently resigned.

THE COLLEGE ACCOUNTS.—The following abstract of the finances of the Royal College of Surgeons, Midsummer 1859 to 1860, has just been published by the authorities:—The Receipts amounted to 22,307*l.*, and were made up from the following sources: Diplomas of Members, 14,355*l.*; Dental Certificates, 929*l.*; Midwifery Licences, 198*l.*; Fellowship Diplomas, 840*l.*; Dividends on Investments, 1207*l.*; and Sale of Stock, 4756*l.* The Disbursements amounted to 21,906*l.*, and are thus distributed: 1. College Department, including Council, Court of Examiners, Dental Board, Midwifery Board, Auditors, Diploma Stamps, Lists of Members, Salaries, Wages, Coals, Law Expenses, &c., 9215*l.* 2. Museum Department, including Catalogues, Specimens, Spirit, Bottles, Salaries, Wages, &c., 2613*l.* 3. Library Department, including purchase and binding of Books, Salaries, &c., 634*l.* 4. Miscellaneous, including Taxes, Insurance, Furniture, Pensions, &c., 747*l.* 5. Repairs, 648*l.* 6. Under Deeds of Trust, including Oration, Lectures, Prizes, &c., 175*l.* 7. Balance of Purchase of House, 43 Lincoln's-inn fields, 7761*l.* The Incidental Income is 21,099*l.*; and the Permanent, 1207*l.* The Incidental Expenditure is 18,173; and the Permanent Expenditure, 3733*l.*

THE ANALYST FOR THE CITY OF LONDON.—At the last Court of Common Council, it was announced that the Secretary of State for the Home Department had sanctioned the appointment of Dr Letheby as Analyst.

SIGHT AND REASON RESTORED TO AN INSANE PATIENT BY AN OPERATION FOR CATARACT.—This interesting case is referred to in our Paris letter of this week, and the following are some additional particulars: M. Bouisson, Professor at the Faculty of Montpelier, lately communicated to the Academy of Medicine the case of a man aged fifty, who was brought to the hospital without any particulars of his case. He was suffering from double lenticular cataract, and from dementia. Couching was resorted to for both eyes; and, on the tenth day after the operation, the man said, "I can see!" these being the first sensible words he had spoken. As the sight improved, the man became more manageable. He began to give some details as to the origin of his ailments; and six weeks after the date of his entrance into the hospital, the patient left, fully capable of earning his own livelihood. To these facts Professor Bouisson added some valuable remarks as to the probable connection between the restoration of sight and the return of intelligence, and stated that he considered that "sensation stimulated the mind as electricity stimulates nervous action, the patient being at the time favourably situated for such impressions." The dementia was probably not deeply rooted, and the organ of sight being that which affords the most vivid sensations, the results have been extremely beneficial as to the patient's state of mind.—'Lancet.'

DR S. B. PARTRIDGE, who distinguished himself in the Lucknow Residency in 1857, has been appointed to officiate as Principal of the Calcutta Medical College. His predecessor, Dr Eatwell, has gone home. Dr S. G. Chuckerbutty, a native, is to act as Professor of Materia Medica.

DR EATWELL, the Principal of the Calcutta Medical College, has published details of the results of the College since its establishment, 25 years ago. At present 85 of the native students are Sub-Assistant Surgeons in Government Service. At least 20 are practising on their own account in Calcutta, and of these several have an income of Rs. 600 a month. The Bengalee educated students practise all over Bengal; 62 are employed by Government as native doctors. Of the Hindustani students, there are 330 with regiments and in hospitals. In 1836 Pundit Modoosoodun Goopto was the first Hindoo who, in spite of caste, dissected the human body. The other Medical Schools in Bombay, Madras, Agra, and Hyderabad have turned out relatively as many medical students.—'Friend of India.'

IN Dr McCleland's report on the health of troops in India we see the following particulars of mortality, compiled by Dr Cheevers. The annual mean rate of deaths for ten years, per thousand men, is for Bengal 65·29, for Bombay 54·44, and for Madras 28·35. The rate of mortality of women per 1000 is, in Bengal 44·4, in Madras 24·7, in Bombay 30·5. The rate of mortality of children is in Bengal 84·2, in Madras 39·8, in Bombay 31·60. The low rates in Madras are attributable to the accessibility of hill sanitaria, and the high rates of Bengal to the prevalence of malaria. In Bengal one-third of the deaths are caused by fever, in Madras one-ninth, and in Bombay one-fourth.

A CHINESE PHARMACOPŒIA.—Toads' flesh cures diarrhœa; that of the *geeks*, tuberculous affections. The flesh of the bat gives long life to those who eat it; its blood and bile have the reputation of curing syphilis, and its excrements are used in the preparation of certain pills. The dried and powdered skeleton of the scorpion possesses diaphoretic virtues, and cures rheumatism and syphilis. The brain of a horse makes the hair grow, its heart dried and powdered strengthens the memory, its bones remove sleeplessness; but they must be the products of a white horse. The marrow of an ass's bones introduced into the ear during sleep cures deafness; rhinoceros's horn cures somnambulism. The urine of the tapir is an antidote against poisoning by copper.—'Gazette Hebdomadaire.'

PHYSICIANS' FEES.—The ordinary fee for a physician in the Elizabethan era was not a guinea. A great noble sometimes gave that sum. It is recorded of a peer in Henry the Eighth's reign, that he paid a fee of 1*l.* to a Cambridge physician, but half that sum was all that usage required. In the reign of Charles the Second, the guinea fee began to be very usually paid; but a doctor was not thought to be badly treated if he received only half that sum. 'Physic lies a-Bleeding; the Apothecary turned Doctor' (1697) represents 10s. as the common fee; and the 'Levanem Infirmi' (1700) says—"To a Graduate in Physick, his due is about 10s., though commonly he expects or demands 20s. Those that are only licensed Physicians, their due is no more than 6s. 8d., though they commonly demand 10s. A Surgeon's fee is 12d. a mile, be his journey far or near; ten groats to set a bone broken or out of joint; and for letting blood, 1s.; the cutting off or amputation of any limb is 5*l.*; but there is no settled price for the cure."—'Athenæum.'

THE BLINDNESS OF GEOFFREY ST HILAIRE.—"His life was shortened by the workings of his mind—by the fire of his powerful imagination. The day did not suffice him; and he passed long

hours of the night, seated on his bed, following out his speculative ideas, and writing down whatever came into his head, and as it were under the dictation of his imagination; a sad habit, for it hastened the occurrence of the blindness which had previously threatened him. It would have been a veritable calamity to him, had he been compelled to ask the hand of a stranger to write down for him every little word. But Heaven had blessed him with a devoted daughter—a pious Antigone, who led his steps and partook of his labours; so, thanks to her, this deep cause of grief became at last a tender melancholy. I have seen this illustrious blind man in his peaceful retreat at the *Jardin des Plantes*, surrounded by his family and friends. His features wore a serene and amiable look; and science, which still exclusively occupied his attention, animated and consoled his beautiful intellect. 'Oh, my friends,' he would sometimes say, 'I in vain seek the light, and yet the sight of animated beings is ever before my eyes.' What regrets he must have suffered, enthusiastic naturalist, incessant contemplator of the marvels of creation! Like blind Milton, he must have wept for his loss of sight—the sight of that splendid *Jardin*, which was his Paradise, his first and last refuge."—'Eloge of Geoffrey St. Hilaire, by M. Dubois.'

At a late sitting of the French Academy of Sciences, Dr Jules Cloquet produced a pair of boots made of the tanned skin of a boa-constrictor. The material is remarkably strong and supple; the scales have preserved their natural imbrication and colour after the process of tanning, and the inside of the skin displays the marks of the scales in alternate reliefs and depressions. Dr Cloquet, on this occasion, observed that it would be desirable to make further attempts to introduce the skins of the inferior vertebrata into trade, seeing that, as to thickness and durability, they decidedly offer greater advantages than those of the superior classes. He concluded by stating that he intended to give one of his specimens to the Museum of Natural History, the other to the Cabinet of the Zoological Garden of Acclimatization.

The late Dr Addison.—The will of this gentleman, late Consulting Physician to Guy's Hospital, was admitted to probate on the 4th instant, and the personalty sworn under 60,000*l.* by one of the executors—viz., John Addison, Esq., of Banks House, Cumberland, the testator's brother; power being reserved to Alfred Brooke Barnes, Esq., Surgeon, of King's road, Chelsea, also an executor. To his relict he has bequeathed his freehold estate and residence at Brighton, together with the furniture, and has left her an annuity of 350*l.* and his shares in the Indemnity Mutual Marine Assurance Company; and to her son and daughter he has left an annuity of 100*l.*; these annuities to be free of legacy duty. The presentation of plate made to him by various parties, both public and private, he leaves to his said brother, to be held by him as heirlooms in the family. He appoints his said brother, John Addison, Esq., residuary legatee of his estate, real and personal. The will bears date September 26, 1855, and a codicil in 1858.

Middlesex Hospital Medical Society.—The first meeting for present Session was held in the Board-room of the Hospital, on Thursday evening, October 18, the Treasurer, Mr Flower, in the chair. After the minutes of the last meeting had been read by the Secretary, and several new members proposed, the Chairman briefly addressed the assembly. He congratulated them on the success which had attended their efforts during the past year; alluded to the advantages naturally accruing from a Society like theirs; urged the necessity of not only becoming members, but of entering warmly into the discussions, stating it as one of the best and quickest means, in his opinion, of gaining information. He likewise impressed on the minds of his hearers the comparative ease with which papers might be produced, owing to the proximity of the wards, and the numerous illustrations contained therein. Dr Cobbold read a paper 'On Tapeworm its Prevention and Treatment.' The very interesting observations of recent naturalists upon the development of tapeworm, and their relationship to the cystic entozoa, were pointed out, and illustrated by diagrams and specimens. The Author then remarked, that to harbour parasitic beings appears to be an almost universal and normal condition of existence. He had himself dissected upwards of six hundred animals belonging to the different vertebrate classes, and had in almost every instance found some form of internal parasite, often many different species and innumerable individuals inhabiting the same creature. Upwards of twenty species of Entozoa are known to infest the human body; of these, four belong to the Tæniadæ, or Tape-worm family, viz., Tænia solium, T. mediocanulata, T. nana, and Bothriocephalus latus. The means of prevention are to avoid the introduction of the creature in its undeveloped, or cystic, condition into the system. In this state it has received the name of Cysticercus cellulosæ, and exists frequently in the muscular tissue of the pig, producing what is commonly known as "measly pork," and which, if eaten in an imperfectly cooked state, will infallibly give rise to tapeworm. The treatment recommended washalf-a-drachm of ætherial oil of male fern, mixed with an ounce of honey, half to be taken at night fasting, the other half next morning, followed in two hours by a brisk purgative. A cordial vote of thanks was accorded Dr Cobbold for his highly-instructive paper, and the meeting then adjourned.

Middlesex Quarter Sessions, October 24th, 1860.—Slaughter-house Licences.—The magistrates met this day for the purpose of hearing applications for licences for slaughter-houses within the Finsbury divisions, and several cases from Clerkenwell and Islington were heard and disposed of. Mr Thomas Cross, of Red Lion alley, within the Holborn district, attended by his foreman in support of a licence to slaughter in Rose and Crown yard, St John street. The applicant stated, that Mr Cross had received notice that his premises were required for the purposes of the new dead-meat market about to be established in Smithfield, and he was anxious to secure new premises for carrying on his business. Mr Meadows, while instructed by Mr S. W. Hopwood, appeared as counsel for the Holborn District Board; and Mr Sleigh, instructed by Mr Keightly, on behalf of the Governors of the Charterhouse, opposed the application. On it being made to appear to the magistrates that the premises in Rose and Crown yard had never been licensed before, and that the proposed slaughter-house would be within fifty feet of dwelling-houses, the magistrates refused to grant the licence. The case excited considerable interest; Archdeacon Hale, master of the Charterhouse, and Mr Turnbull, and several influential inhabitants of St Sepulchre, were present. Mr John Fawcett, of No. 125 St John street, attended with a memorial signed by the Churchwardens, Overseers, and several inhabitants of St Sepulchre, including the Treasurer of St Bartholomew's Hospital. Dr Gibbon, Medical Officer of Health; Mr Isaacs, the Surveyor, and Mr Easton, the Inspector, attended to give evidence on behalf of the District Board.

Medical Trial: Michael v. Lea.—The plaintiff in this case is a fully-qualified practitioner at Newcastle, and the defendant a farmer; the action being to recover the sum of 2*l.* 2*s.* for attendance upon the latter, and 1*l.* 1*s.* 6*d.* for attendance and medicines for his servant, supplied at his request. The first item included a charge for adjusting temporarily a compound fracture of the arm when called hastily at the time of the accident, and visiting the patient three times at seven miles' distance. If any fault could be found, we think it should be that the fee of 2*l.* 2*s.* was unreasonably small for such services. As to the second item, it was submitted that the defendant had acted only as messenger to his cowman, and had requested Dr Michael to attend to him in that capacity only. This defence also broke down, and judgment was given for the plantiff.

APPOINTMENTS FOR THE WEEK.

Wednesday, October 31.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.
Hunterian Society.—8 p.m.

Thursday, November 1.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.
London Surgical Home.—2 p.m.
Harveian Society.—Mr Sedgwick, "On Sexual Limitation in Hereditary Disease," 8 p.m.

Friday, November 2.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, November 3.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, November 5.

Operations at the Royal Free Hospital, 2 p.m.; Metropolitan Free Hospital, 2 p.m.
Medical Society of London.—8½ p.m.

Tuesday, November 6.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

Amicus.—The Report has come to hand, and a notice been given of it.

R. D.—Theories of life are highly interesting to their concoctors, but not so to the general reader. There are limits by which human reason is bounded in the consideration of this question,—a sufficient motive for some men to attempt to transcend them. If a man be a positive materialist, and say that life is exclusively the result of the properties of "common matter," his case is so simple that it cannot be misunderstood; but if he admit a distinct vital principle, or anything equivalent to it, he will find it difficult to prove to the satisfaction of his readers that he has found the link connecting his vital principle with matter. As we cannot discover that you have done this, we decline the communication.

Chinurgus.—Certainly.

W. S.—The Guardians are not bound to pay the extra fee in the case cited; should they do so, it will be purely an act of grace.

Dr H.—There would be no incongruity in a Licentiate of the College of Physicians of Edinburgh styling himself Dr, and placing the letters L.R.C.P. after his name. He ought not to imply that he is an M.D.

Birmingham.—We are not acquainted with the precise title of Professor Youatt's book, but any bookseller will provide it for you.

Mr Thomas Lyte.—We cannot give you more authentic information than has been already given to you by Mr Belfour. The regulations of the College are the only ones at present that are binding.

M.D. (Dublin) is thanked. The subject will not be forgotten.

X. X.—The case is probably one of lupus non-exedens. Try cod-liver oil or arsenic.

Mr Ward.—Received.

Mr Baker.—1st. Yes.—2nd. Yes.

Mr B. C.—It is quite a mistake to suppose that phthisis is not a frequent disease in the South of France and Italy. There is no part of France where consumption is so common as Montpellier and Marseilles; and at Nice there is a greater mortality from consumption than in any town in England. As for Malta, the death-rate from this disease is as high as it is in England.

A Student.—You will be exempt from any future regulations.

Medicus.—Dr Budd's and Dr Brinton's.

A Subscriber is thanked.

The Educational Regulations of the Medical Council.

Sir,—I have read with some surprise the letter of Dr F. Hawkins in your last Number. I quite agree with you that apprenticeship is a great sham in relation to a Medical education; but still you must recollect that to all who entered the Profession with the intent to become General Practitioners, it was the only way of entering before the establishment of the Medical Council, and even now remains so: it is compulsory, by Act of Parliament, on the Apothecary, and admitted as a part of Professional education by the College of Surgeons. Under these circumstances, what right have the Council to make a retrospective law affecting those who had already legally entered the Profession before the Council had any existence? Is there no appeal to any Court of Equity to try such a case? You must be aware that a large number entered the Profession not prepared to pass such an examination, inasmuch as such was not required when their parents paid two or three hundred pounds premium,—supposing, on the faith of Acts of Parliament and College laws, that such was the right way to commence a Professional education.

I trust, with your efforts to secure justice in other cases, you will not withhold your powerful aid in redressing this wrong; and am, dear Sir,

Yours, &c., A Father.

London, Oct. 25.

To the Editor of the Medical Circular.

Sir,—In reference to the extract from the 'Indian Lancet' on the licensing and medical inspection of bazaar-women for the prevention of venereal disease in the Army, I would suggest that women be the examiners of the unfortunate women, for most assuredly the male examiners must suffer by the contaminating influence. There is a continued reciprocating influence between mind and body. If your liberality of principle will admit you to insert this, you will oblige

Yours, &c., Sanitas.

Chlorodyne.—R. Freeman,

Pharmaceutist, Kennington road, London, S., informs the Profession and Trade that he has FOR YEARS MADE, and extensively used in his business, Chlorodyne; and that he is supplying it in one-ounce stoppered bottles at 1s.6d. each, and in four-ounce bottles, 5s. each. He guarantees it to be uniformly and properly prepared, and superior to any other makers', though their charge be ever so exorbitant; and he trusts that the lowness of price at which he offers it will allow the Profession to use it in common practice and at public institutions, so that its extraordinary beneficial effects may be enjoyed by the poorest sufferer. Sold by all Wholesale Druggists.

Fennell's Celebrated White

STOPPING (warranted to keep its Colour in the Mouth) reduced to 8s. per oz. Sold in ½ oz. and ¼ oz. packets, sent by post upon receipt of stamps for the amount. Mechanical Dentistry in all its branches. Work done for the Profession. Instruction in Mechanical Dentistry.

Mr F.'s Charges to the Public are, for a Mineral Tooth, mounted in pure silver, 5s; ditto in gold, 10s. 6d.;—Stopping Teeth with his White Stopping, 2s. 6d.

Price Lists sent upon application to Mr FENNELL, Dentist, 36 Upper Berkeley street, Portman square.

WATER MATTRESSES & CUSHIONS, For Bed Sores, Consumption,

Paralysis, Fevers, and all Invalids and Bedridden Patients. Air Cushions and Pillows, Bed Sheets, Elastic Stockings, Enemas, Ear Trumpets, Railway and Bed Urinals, Bed Pans and Slips, &c.

WILLIAM LEE, 115, NEW BOND STREET, W.

Water Beds on Hire, 7s. per Week. Deposit, £10.

TO THE PROFESSION.

Messrs M'Gowan & Danks

(THE PRINTERS OF THIS JOURNAL)

Are prepared to forward Estimates, to those requiring the same, for any description of Work connected with the Printing Business.

Messrs M'G. and D. are enabled, from the facilities which they possess, to execute whatever may be entrusted to them with economy and despatch.

Letters addressed to No. 16 GREAT WINDMILL STREET, HAYMARKET, will meet with immediate attention.

*** There is at the present time an opening for the Printing (and Publishing if wished, of a Weekly Periodical.

Flat Silver Watches—

Four Holes Jewelled and with true Sunk Seconds—£1 18s.

FLAT GOLD WATCHES—Eight Holes Jewelled, of a higher character, with White Dials and true Sunk Seconds—£6 6s.

The above are Sample Watches (Horizontal Principle) and such as within the large experience of this Old Established House we have never been able to offer at less than Three Guineas in Silver, and Ten Guineas in Gold Cases.—All warranted.—Per Post, 1s. extra.

Particularly suited for Students and Gentlemen of the Medical Profession.

ARNOLD, 59 and 60 Red Lion street, Holborn, London.

Kinahan's LL Whisky v.

COGNAC BRANDY.

This celebrated old IRISH WHISKY rivals the finest French brandy. It is pure, mild, mellow, delicious, and very wholesome. Sold in bottles, 3s. 6d. each, at most of the respectable retail houses in London; by the appointed agents in the principal towns in England; or, wholesale, at 8, Great Windmill street, Haymarket.—Observe the red seal, pink label, and cork branded "Kinahan's LL Whisky."

Catalogues gratis.

Bank of Deposit, Established A.D. 1844,

3 PALLMALL EAST, LONDON.—CAPITAL STOCK £100,000.

Parties desirous of INVESTING MONEY are requested to examine the Plan of THE BANK OF DEPOSIT, by which a high rate of interest may be obtained with ample security.

Deposits made by Special Agreement, may be withdrawn without notice.

The Interest is payable in January and July.

PETER MORRISON, Managing Director.

Forms for opening Accounts sent free on application.

TO SURGEONS, DENTISTS, &c.

The Best House in London

for SECOND-HAND INSTRUMENTS is Mr WM. LAWLEY'S, Lombard House, 78 Farringdon street, City.

Established upwards of a century.

A first-class full SURGEON'S ARMY CASE for Sale.

N.B. The largest stock of Second-hand Dissecting Cases in London. Also, A great variety of New and Second-hand Army and Navy Regulation Cases.

Instruments Bought, Sold, or Exchanged.

PULVIS JACOBI *VER.*, NEWBERY'S.

GENTLEMEN,—We beg to call your attention to the following paragraph by "*J. Cheyne, M.D.*, Phyſician to the Hardwicke Fever Hoſpital, Dublin, *in his paper on the virtues of James' Powder in the Apoplectic Diatheſis*:"

"She began a courſe of James' Powder in the latter end of September: the firſt night ſhe took only two grains, and every ſucceeding night an additional half grain, till the doſe amounted to twenty grains. She took *twenty grains every night for five weeks*, when ſhe found herſelf ſo well that ſhe diſcontinued the medicine."—"*Dublin Hoſpital Reports*," *vol.* 1. *p.* 319.

To ſecure the diſpenſing of the *original* preparation, which, for 114 years, has been ſold by the Newbery family in St. Paul's Churchyard, it is neceſſary to preſcribe it as "*Pulvis Jacobi* Ver., *Newbery's*," otherwiſe another article (wanting in the beſt properties, and recommended to be given in a different code of doſe, *though called by the ſame name*), will be ſubſtituted for the original medicine. This, of courſe, cannot but have an effect other than that expected, and will thereby lead the practitioner totally to diſcard it from his daily Pharmacopœia, as a preparation whereon no dependance can be placed. We hope the above extract will prove that when the genuine medicine is uſed, faith may be repoſed in it.

Yours faithfully,

F. NEWBERY & SONS.

45, St. Paul's Churchyard.

S. Bowles (late Windsor and Co.),

PHIAL and BOTTLE MERCHANT, Dealer in Druggists' Sundries, &c., 6 James street, Covent garden, W.C. The cheapest house in London for every description of MEDICAL GLASS of the best quality.

Samples and prices forwarded free on application.

Antimargaric Cod-liver Oil,

Pure and Tasteless, sold by H. ELDREDGE, Wholesale Agent, for Messrs WM. & EBENR. ROTTON, at their Depôt, 85 Pentonville road, London, and by most respectable Chemists throughout the kingdom.

This Oil, extracted by W. and E. ROTTON, possesses all the medicinal properties essential in cases of Consumption, Diseases of the Chest, Infantile Wasting, general Weakness, &c.; and for many ills the human frame is heir to, there is not its equal. In order to prove its superiority over every other, it has been subjected to the most scientific Analysis, as proved by Testimonials received from the following well-known Physicians:—WM. HERAPATH, F.C.S., of Bristol; JOHN POSTGATE, M.D.; Dr BELL FLETCHER, M.D.; D. W. CROMPTON, M.D.; WILLIAM SANDS COX, Senior Surgeon of the Queen's Hospital, Birmingham; and many others of equal eminence.

Dr SEPTIMUS GIBBON, A.B. & M.D., Medical Officer of Health, late Professor of Natural Philosophy at St Bartholomew's Hospital, Physician to the London Hospital, &c. &c., of No 3 Finsbury square, London, E.C., whose recent investigation under Government brought to light such an alarming extent of adulteration in articles of diet, writing expressly upon Messrs W. & E. ROTTON'S Antimargaric Cod-liver Oil, uses the following expressions:—

"I have carefully examined some bottles of Messrs W. ROTTON & SON'S Cod-liver Oil, and find them to be excellent samples of pure Oil. Besides answering admirably to the usual tests, it is free from the noxious and nauseous principles, Margaric Acid, &c., which so commonly render Cod-liver Oil not only unpalatable, but indigestible and injurious to the human stomach. By their mode of extracting and preparing this admirable remedy, I feel satisfied they have overcome the main obstacle to its more frequent and general use in medical practice."

The Antimargaric Oil is sold in pint bottles at 2s. 6d.; half-pint, 1s. 3d.; quarter-pints, 8d. Where a difficulty is found in obtaining it, write direct to the Depôt, when a case will be forwarded for the amount of 5s. or 10s., carriage free.

None is Genuine unless Capsuled, and Signed WILLIAM and EBENEZER ROTTON.

W. Twinberrow begs to

draw the attention of the Medical Profession to his EXTRACT of INDIAN HEMP, prepared expressly for him at Calcutta, its peculiar sedative properties being so beneficial where opiates are inadmissible; also to his MEDICINAL EXTRACTS, prepared from the fresh plants (Hyoscyamus Niger, Conium Maculatum, Atropa Belladonna, Cotyledon Umbilicus, &c.); also to his Liq. Taraxici, Liq. Galli Aparinis (a valuable alterative), Liq. Pareiræ (diuretic), and Liq. Belæ (prepared from the Ægle Marmelos, or Indian Bael) for Dysentery and Diarrhœa. W. T. has a large supply of INDIAN BAEL on hand.—Agent for Palmer's Aerated Chalybeate Water.—EXT. LARICIS EUROP.

BOUDAULT'S PEPSINE imported in Original Corked Bottles by W. TWINBERROW, 2 Edwards street, Portman square.

Surgeons receive Appointments to SHIPS to ALL PARTS of the WORLD through

F. G. MOORE, M.R.C.S.,

34 TERRACE, TOWER HILL, LONDON.—E.C.

Gentlemen requiring Appointments are invited to forward their names.

SURGICAL INSTRUMENTS required by Surgeons to Ships always ready.

PORTABLE SURGERIES for Medical Men in General Practice.

MEDICINE CHESTS for Ships and Passengers. COMMISSIONS promptly executed. The PURCHASE and SALE of PRACTICES. VALUATIONS of STOCK and FIXTURES. ASSISTANTS provided. Business hours, 10 to 5.—Send stamp for reply.

A New Discovery.—Mr

HOWARD, Surgeon-Dentist, 52 Fleet street, has introduced an entirely NEW DESCRIPTION of ARTIFICIAL TEETH, fixed without springs, wires, or ligatures. They so perfectly resemble the natural teeth as not to be distinguished from the original by the closest observer; they will never CHANGE COLOUR OR DECAY, and will be found very superior to any teeth ever before used. This method does not require the extraction of roots, or any painful operation, and will give support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication; and that Mr Howard's improvements may be within the reach of the most economical, he has fixed his charges at the lowest scale possible. Decayed teeth rendered sound and useful in mastication. 52 Fleet street.

At home from ten till five.

James's Fever Powder.

4s. 6d. per bottle; packets 2s. 9d. each.

Prepared and sold by J. L. KIDDLE, 31 Hunter street, Brunswick square, London.

This Preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remark on the part of the Proprietor unnecessary. To be had of all Wholesale Druggists.

The Pulvis Jacobi Verus,

prepared by WILLAM HOOPER, 24 Russell street, Covent garden, from its identity with the more costly preparations and its acknowledged efficacy as an Antimonial, merits the patronage of those Gentlemen who have not hitherto included Pulvis Jacobi in their daily Materia Medica. An extensive continuous demand, for Public Institutions, has satisfactorily verified the ancient character of this medicine. It is sold in 1 oz. and 4 oz. bottles, at 2s. 9d. and 10s. 6d.; and in packets for transmission by post.

To Gentlemen.—Mr Miles,

(Alfred Webb Miles,) Established 18th February, 1841,

Originator of the WORLD-FAMED TROUSERS, at 16s. per pair, has the pleasure to inform thirty thousand customers that his stock for the forthcoming Winter is now replete with all the new and best designs for Over-Coats, Morning and Travelling Suits, Vests, Trousers, at prices as heretofore. Gentlemen who have not already favoured this establishment with their interest and support are most respectfully informed that it is distinguished not only by the extent, variety, and quality of its patterns and materials, but it excels in the cut and workmanship.

CAUTION.—Mr Miles is not connected with any person imitating and advertising in the same name; his only address is 73 Brook street, Hanover square, and he has no other establishment in London or elsewhere.

DINNEFORD'S

Pure Fluid Magnesia,

now greatly improved in purity and condensation.

"Mr Dinneford's Solution may fairly be taken as a type of what the preparation ought to be."—'Pharmaceutical Journal,' May, 1846.

This excellent remedy, in addition to its extensive sale amongst the public, is now also very largely used for DISPENSING. In the stone jars (half-gallon, 5s. 6d.; gallon, 9s. 6d.,) specially adapted for the use of Surgeons and Chemists. To be had from the Manufacturers.

DINNEFORD and CO., Chemists, 172 Bond street, London; all Wholesale Druggists and Patent Medicine Houses.

CLINICAL LECTURES.

ON DISEASES OF WOMEN.

DELIVERED AT ST THOMAS'S HOSPITAL,

By CHARLES WALLER, M.D., Obstetric Physician to the Hospital.

Lecture II.—On Polypus Uteri.

(Continued from page 268.)

At the conclusion of our last Lecture, gentlemen, I showed you the mode of applying the ligature in cases of uterine polypi. I have made, at the suggestion of my son (at present one of your number), a slight alteration in the barrel affixed to the lower part of the instrument: instead of the hook around which the two ends of the ligature are tied, I have, in the barrel, two openings corresponding to those of the canula above. The ligature is, as I now show you, passed through the foramina, the ends tied tightly together in the centre, and the superfluous thread cut off. Now, what advantage has this over the hook? Trifling as the alteration appears to be, I assure you in practice it is a great improvement. Contrast the working of the two instruments. In the original one, there is more difficulty in making the knot tight when passed around the little hook, and, in turning the barrel round, it will sometimes slip off. Then, again, the two ligatures and the knot are apt to become somewhat entangled with each other after several turns of the instrument, and its free action impeded. No such obstacle can possibly occur in the instrument I now exhibit. You will perceive that the two ligatures are kept widely separated, and the knot revolves *between* them. Let me now detail to you the progress of the case operated on after our last lecture. You saw the way in which the ligature was passed around the upper part of the polypi: during the introduction of the instrument there was rather free bleeding (much more than ordinarily occurs), which ceased immediately after the ligature was tightened; not the slightest pain was felt, and the patient was left in a very comfortable condition; the parts were ordered to be sponged with cold water, nourishing diet so far as it could be taken to be continued, and no medicine prescribed.

Next day (October 20), no inconvenience felt, with the exception of the desire to urinate frequently, and some little difficulty in the act. This symptom was not a new one, it had been present for some weeks; perhaps it had been slightly aggravated in consequence of the instrument lying in the anterior part of the vagina, and thus pressing somewhat on the meatus urinarius. If you ask why, with a knowledge of this fact, the instrument was not placed on the opposite side of the pelvis, I would refer you to the history of the case. You will remember that the *entire circle* of the os uteri could not be distinguished, it was only anteriorly that it could be felt away from the tumour; on this account, I selected this locality as the starting-point of my ligature. The catheter was introduced, and a pint and a half of clear urine removed. The ligature was also tightened by two or three turns of the barrel.

Oct. 21.—Feels comfortable, although the bladder has not been satisfactorily emptied; ligature was also tightened by two or three turns, it having become loose; catheter employed; slight fœtor.

Oct. 22.—Fœtor increased; ligature firm.

Oct. 23.—Discharge extremely fœtid; ligature firm; slight extracting force made without effect.

Oct. 24.—Ligature tight; substance of polypus greatly diminished in size; firm traction brought away the instrument, with the polypus attached to it. I show you the tumour, resembling, as you perceive, a large bag containing a hard substance.

Thus, gentlemen, has a disease which has been for twelve months weakening and depressing the patient's constitution, and even threatening her existence, been removed by a simple, painless, and usually (though not entirely so in this case) bloodless operation.

The ligature I employ consists of silver wire twisted round a strong silken thread. I prefer this to any other material, not only because of its firmness, but also because, although in a very trifling, yet to a certain extent, it *cuts* its way through the pedicle: where this is thick and firm, the cure is more speedily effected than where the surface of the ligature is altogether smooth.

During the progress of cure, should the discharge become very offensive, the vagina should be washed out with tepid water, or with a weak solution of chloride of lime.

In a polypus of moderate size, the cure is usually effected in from four to six days; and although the stem may not be entirely separated, the small undivided portion is easily torn through, if the instrument be grasped by the hand, twisted round, and a moderate degree of extracting effort made at the same time. Do not be too anxious, however, if a longer period of time be required; for if the ligature be properly applied, the cure is certain, although it may be protracted.

In some forms of polypus, although of considerable size before they are tied, there is scarcely any solid substance to be seen after strangulation has been effected; the mass, to use a popular expression, dwindles into almost nothing. The following case is one amongst many examples which have fallen under my notice.

Case 3.—M. Ripping, admitted into Ann's Ward, ætat. forty-nine, married, has borne thirteen children: her countenance is pale, and has an anxious expression; she has had more or less bleeding for eighteen weeks. On examination, a polypus of considerable size was felt projecting through the os uteri. The surface was peculiarly smooth, and the substance much less firm than in the cases previously detailed to you. A ligature was applied, which came away in three days, bringing with it the remnant of the tumour, in appearance similar to a piece of shrivelled skin, far gone in a state of putrefaction.

A polypus distinctly felt at one time, may disappear for a greater or less period, and in some cases seem to vanish altogether, the patient experiencing no more unpleasant symptoms.

Case 4.—Rebecca Cole, ætat. twenty-eight, single, cook in a gentleman's family, has had hæmorrhage for nearly three months; had leucorrhœa previously. She was examined on admission. The os uteri was to a considerable extent open, and a polypus felt descending from the interior of the uterus. The substance, however, had not yet passed into the vagina. Large doses of gallic acid were administered, and perfect rest in the recumbent position enjoined: the hæmorrhage soon ceased. At the expiration of five weeks, there being no alteration in the size or position of the tumour, a different plan was adopted: secale was given three times daily, and the patient desired to move about, in the hope of expediting the descent of the polypus. Hæmorrhage supervened, but no other result followed. As the female was very anxious to return home, an attempt was made to apply a ligature, which was not attended with success. The manipulation produced considerable bleeding, which was arrested by the exhibition of secale cornutum. After an attack of diarrhœa which somewhat weakened her, she felt perfectly well: when examined, the os uteri was closed, so that nothing could be felt beyond it. She was now discharged apparently well. About two years afterwards, she was again admitted into the hospital. Her strength was reduced, her countenance exceedingly pale and blanched; she had had profuse monthly discharges since her last sojourn in the hospital, until within the last eight weeks: since then the hæmorrhage has occurred every fortnight. On examination, the os was found partially open, and a small moveable body felt within the uterine cavity. I succeeded in introducing the index-finger of my right hand beyond the bulging portion, and scraped off its attachment to the womb, bringing the polypus away in my hand. Very little pain was experienced, and no hæmorrhage occurred: indeed, the regular catamenial discharge did not make its appearance until eight weeks afterwards, this time continuing three days. The patient was dismissed thoroughly restored to health.

I direct your attention to another case, wherein the polypus disappeared for a few days only.

Case 5.—Anne Bead, admitted 26th, ætat. forty-two, has had seven children, the last seven years old. About nine months ago, was attacked with severe hæmorrhage, which has continued at intervals ever since: has great pain in the left inguinal region, with some swelling of the lower extremities; general health enfeebled. When examined, the os uteri was found slightly open, and the base of a polypus just within the reach of the finger. The bowels being confined, a mild laxative was administered; afterwards pulv. secalis cornuti ℈j. was given for two days without any marked effect. The patient was again examined about ten days afterwards, when I found the os completely closed, leaving no trace of the tumour.

Jan. 22nd.—Again examined. A considerable portion had escaped through the uterine mouth, projecting into the vagina. Although the pedicle was out of the reach of the finger, I determined to apply the ligature, and to carry it up within the cavity of the womb. As the os was quite free, this was effected without much difficulty. The ligature was tightened day by day, until Feb. 22nd. The tumour was considerably lessened in size, and the discharge was offensive: becoming a little impatient, I exercised too much force in winding up the instrument, and broke the ligature. A very small portion of the polypus came away with the canulæ. The uterus still felt enlarged, tho os open, and no portion of the polypoid growth within reach. On the 5th a large mass came away, after which the patient rapidly gained strength.

The discharge in polypoid growths is sometimes so exceedingly offensive, that carcinoma, or sloughing, may be suspected.

Case 6.—Ann Meary, æt. thirty-six, domestic servant, admitted April 9th, has always been in delicate health: has had frequent hæmorrhage for the last eighteen months, with great "bearing down;" her countenance cadaverous; she is unable to pass urine. The fœtor of the discharge almost unbearable. This symptom excited a suspicion that sloughing had taken place. Before making an examination, I directed the vagina to be thoroughly washed out with cold water, and afterwards with a weak solution of chloride of zinc. A large polypus was found occupying the vagina, the stem passing through the os. A ligature was applied in the usual manner, which was brought away in seven days. The patient had a good recovery.

Case 7.—Mrs G——, æt. forty-two, the mother of several children, had lost much blood, principally at her monthly periods, for many years. Being one of the deluded followers of homœopathy, nothing effectual had been done for her relief, until her health became seriously injured, and her life im-

perilled. Her peculiarly cadaverous look, and the fœtor of her discharge, led to the supposition that the disease was carcinoma uteri. This opinion was given by a physician-accoucheur of considerable celebrity at the west end of the town, who said that nothing could be done for her relief, and that her life could not be protracted for many weeks. Soon afterwards I was requested to visit this lady. Her general appearance was, to say the least, very discouraging. She had a peculiarly sallow, unhealthy, anxious-looking countenance. Her strength had been greatly reduced by the repeated hæmorrhage to which she had been subject, and, as might have been anticipated, her spirits much depressed. On examination, a large tumour was felt occupying the whole cavity of the pelvis, polypoid in shape, slightly moveable, although not so much as usual on account of its large size. The finger could not be passed high enough to touch the os uteri. The fœtor evidently arose from blood which had become putrid. I gave an unhesitating opinion that a ligature should be applied, although no distinct pedicle could be felt. Mr De Morgan, of the Middlesex Hospital, saw this patient with me at my next visit, and agreed with me as to the non-malignancy of the tumour: I therefore at once passed the silver wire round it. Day by day the ligature was drawn tight, apparently without effect: no additional fœtor was noticed, and no diminution in the size of the tumour. On the fifth day the ligature was broken, but not before it had done its work; for although the polypus was not completely separated at the time, it was expelled a few days afterwards, to use the words of the patient's friend, in the form and "the size of a turnip." A microscopical examination demonstrated it to be of a fibrous character, free from any appearance of cancerous deposit. Polypi sometimes grow to an enormous size within the cavity of the uterus, which enlarges as in actual pregnancy, and at length suddenly forces the substance into the vagina with powerful action resembling the pains of labour. The following case affords an illustrative example. I shall not weary you with a tedious detail of symptoms, or of the palliative treatment adopted, but shall content myself by giving the result of the examinations as they were made from time to time.

Case 8.—Mrs C., residing in the country, consulted me for the first time July 9th, 1857. She was forty-seven years of age, had been sixteen years a wife, but had never been pregnant. For the last three years, she has suffered most agonising pains at her menstrual periods, with profuse hæmorrhage, attended with vomiting: in the intervals leuchorrhœal discharge was constant, occasionally tinged with blood. Complains of bearing down; although the appetite is tolerable, she is gradually getting thinner; has occasional rheumatic attacks; is distressed by flatulence. On examination, the uterus was found enlarged and heavier than usual, and somewhat prolapsed: when seen through the speculum, the vaginal membrane was highly vascular; the portion reflected over the cervix uteri of a bright vermilion colour, and slightly tender to the touch. She came to town at intervals during the months of July, August, and September, the uterus continuing to increase in size and weight; and at the end of the latter month, the cervix uteri, which had been gradually shortening, was distended as perfectly as in the latter periods of gestation. No relief from suffering at her monthly periods; os uteri still closed.

Nov. 16th.—Os beginning to open; a large moveable body felt in the uterus.

Dec. 17th.—Os still more patulous; no descent of tumour; very little alteration, except that the os was more dilatable; her sufferings every month were still acute. On the 12th of May, 1858, the finger could be introduced high up in the uterus; the tumour still contained within the cavity. I recommended my patient to come to town again at her next catamenial period, hoping that during that time I might be able to reach the upper part of the tumour. She came again, rather before the appointed time, in consequence of increase of pain and bearing down. On examination, the polypus, which was of very large size, was found occupying and filling up the vagina; the ligature was applied without delay, and by the end of the week the disease was removed, and the patient, after a protracted period, regained her health and strength.

Polypi are sometimes expelled by the efforts of nature alone, as in the following case:—

Case 9.—Saw Mrs ——, in consultation with Mr Complin. She had suffered from severe hæmorrhages for some time. When I saw her, the uterus was acting forcibly. On examination, the os was opening, and a firm, moveable substance felt in the cavity. I recommended nothing to be attempted, but to wait and see what these powerful uterine contractions would accomplish. Mr C. informed me that some time afterwards a polypus of considerable size had been expelled, to the relief of all unpleasant symptoms.

Polypi are occasionally met with where, from their size and hardness, they cannot be removed by the hand.

Case 10.—Saw Miss ——, in consultation with Mr Harris. The substance was of enormous size, and after the pedicle was separated, the polypus could not be removed by the usual manipulation. It was at last extracted with a pair of stout stone forceps.

Had this lady been married and borne children, it is probable that the hand might have been introduced within the vaginal cavity, and the polypus brought away without the use of instruments.

TWO CASES OF PURPURA HÆMORRHAGICA.

By JOHN GASON, M.D., &c.,
Member of the Society of Quirites at Rome.

(Continued from page 283.)

Purpura hæmorrhagica is a disease still wrapped in much mystery, and the difficulty of forming any correct idea of its nature has given rise to various opinions, which may be classified as having reference to the sanguineous and nervous systems, sometimes in a sthenic, but most frequently found to present itself in an asthenic form. It appears to me that its causes may be attributed, in the first place, to a chemical decomposition or derangement of the component parts of the blood, produced by the absorption into the system of a morbific poison which deranges or decomposes its chemical affinities; secondly, to a loss of nervous power in the organs which supply the fibrine and serum of the blood, thus modifying or destroying the properties of the chyle; and, thirdly, to a diminution, more or less, of the nervous power derived from the nerves which supply the blood-vessels, which not only favours this change in the blood, but also extends to the capillaries, thus weakening their tone, and allowing of the escape of blood in its decomposed state or deprived of its fibrine. It now remains to examine under what conditions the blood escapes, and what are the chemical changes which allow of its escape, and how the changes are effected. It is well known that individuals of a sanguineous temperament, in whom the venous system predominates, are those most predisposed to typhoid and contagious fevers: it may be that they are more prone to inhale putrid animal miasma or exhalations of a contagious nature; or it may be that their blood is not sufficiently oxidised, which disposes them so much to this influence. I believe that this preponderance of venous blood in the sanguineous temperament is the consequence of an unhealthy state of the nervous ganglia acting throughout the body, whereby the supply given to the blood becomes degenerated, and that which in a healthy state of the system would have renovated the blood with proper sustenance becomes converted into a fluid wanting in sufficiently active properties. It has been of late the fashion to underrate the evil consequence of noxious effluvia: and not only this, but statements have been made that nightmen, and persons engaged in occupations which bring them into contact with fœtid exhalations, are generally men of portly mien and of good constitution. I grant that they are very often large, fat, and bloated; but this is, I believe, the result of the decomposition or derangement of the chemical affinities of the blood. It is in this description of persons that the large proportion of typhoid fevers, delirium tremens, and nervous affections are found, as well as purpura hæmorrhagica, and diseases indicating debility of the nervous system—who, though apparently in the possession of good health, have in themselves the seeds of diseases most difficult to cure. In order rightly to understand the effect produced on the blood by particular states of the atmosphere, and by the inhalations of noxious vapours, as well as by the indulgence in practices very debilitating to the constitution, it will be well to consider, in the first place, the physiology of the blood. The most accurate investigations have shown that the red globules of the blood are each surrounded by an envelope or cyst, containing fluid in which the globule floats: this cyst is colourless, transparent and remarkably thin, and is supposed to partake more of the nature of fibrine than of any other known substance in the animal kingdom. The red globule contained in the cyst is composed of two substances, globuline and ematosine. The substance called globuline is supposed to possess many properties in common with the albumen of the serum. Ematosine, though insoluble in distilled water, is very much so in alcohol acidulated with various acids. It is also very soluble in alkalies and various gases. What, then, are the uses of this cyst which encloses the globule, as well as of the fluid in which it floats? I believe that they are principally for the protection of the globules from the various gases to which they are exposed, for preservation from shocks, for nutriment and the preservation of an equal temperature.

When the healthy nervous power derived from the ganglia which surround the blood-vessels is weakened by any debilitating cause, the vitality which the component parts of the globule should possess becomes weakened, and allows of its contents being subjected to various chemical combinations in the blood, derived from the atmosphere, or taken into the system by various means and from various morbific sources. By this means the involucrum of the globule in its weakened state allows the absorption of various deleterious agents, while in others it may be completely destroyed, and the poisonous agent is brought into immediate and more powerful contact with the globule, which in its injured state is hurried through the lungs and capillaries, and though subjected to the oxygen of the air, fails to receive the necessary vivifying power from it. It thus fails to supply the system with the same healthy nutriment as before; the consequence of which may be an unusual deposit of adipose tissue, or a nucleus of diseased organic matter, &c., among the solids, and a depraved state of the blood, giving rise to various diseases too numerous to mention here.

The second of the cases of which I have given the history appears to be one of those in which nature attempted to relieve itself by crisis; but either from some organic defect in the sudatory system, or that the blood oozed from the vessels, it was poured into those parts in which it was found in the post-mortem examination.

I have examined into the history of twenty-seven cases of purpura hæmorrhagica, upon which I would make the following remarks:—It is a disease which equally attacks males and females, and is for the most part found in youth. In most of the cases which I am referring to, it was a primary disease, but occasionally occurred in a secondary form. It is a disease of a very serious nature, having proved fatal in half of the cases alluded to. In nine cases, post-mortem examinations are recorded; in six of these the brain and its membranes were affected, varying from petechiæ and increased vascularity to effu-

sion of blood into the substance of the brain. In six cases the lungs and pleura were the seat of disease, with petechiæ and effusion into the pleura, and in some infiltration of the substance of the lungs with blood. In six the heart is described as pale and flaccid, in two as fatty. In four the liver was pale, in some soft. In two there was enlargement of the kidneys. In eight out of the twenty-seven cases, turpentine formed the principal treatment; and of this number fatal results took place in three. In ten cases out of the twenty-seven, bleeding and antiphlogistic treatment was employed; and in seven of these, fatal results took place.

From the careful consideration of many cases which have been under my care, as well as from the history of those which I have alluded to, I conclude that purpura hæmorrhagica is a disease not necessarily connected with a previously cachectic state of body, but most probably with a deranged and abnormal state of the functions, and with a diseased state of the absorbent and excreting powers; secondly, that a debilitated state of the nervous system tends to produce a depraved state of the blood, with its unhealthy consequences, as stated before; and thirdly, that the best treatment for the cure of this disease in an asthenic state consists in the exhibition of turpentine as soon as possible after the nature of the disease has been ascertained, without regard to any other with which it may be complicated.

The debilitated state of the nervous system I attribute in great part to the indolent and unhealthy habits which society has adopted, a cessation of active out-of-door exercises, and inhabitating localities whose atmosphere is impregnated with noxious effluvia.

Rome.

ON THE NON-DIGESTION OF FAT,

CONSIDERED IN ITS SPECIAL CORRELATION WITH AFFECTIONS OF THE PANCREAS.

By Dr E. ANCELET, of Vailly-sur-Aisne.

(Translated for the Medical Circular.)

Without abandoning the domain of experimental inquiry—too exclusively cultivated in the present day—a time must come when physiology will deal with facts in a manner more decided than heretofore, and taking in a more exact fashion the data furnished by clinical observation, will compare them with the results of experiment, in such a manner as to enable us to controvert or confirm, discover new points of view or suggest new subjects for research—consequently enabling us in every case to render its applications more direct and more immediate. When this legitimate alliance shall be established, we shall be better able to appreciate the connection existing between the resulting phenomena and the organic lesion; therapeutics will then be reared on more solid ground, and the foundations of physiology will be more compactly laid. The importance which modern investigations, those especially of Claude Bernard, have given, on the one hand, to the pancreas in connection with the digestion of fat; and on the other hand, the numerous objections that have been raised against this view,—give to everything relating to this subject a real interest.

Occupied with a work on the diseases of this organ, for which I have collected nearly 350 cases, it was incumbent on me to examine such as could throw light on this relationship, and to see whether pathological facts really concur in proving the physiological theory—whether this gives a clear interpretation of them, or whether, it may be, they have not indicated some inappreciated peculiarity, some cause of error in the experiments compromising their accuracy and rendering their interpretation less conclusive, and so throwing doubt over the whole.

According to the theory, when the pancreas is affected the digestion of fat is at an end, or at least is less perfect; for fatty matters are rejected, and no longer serve the purpose of nutrition. I shall therefore consider the vomiting and the dejections, as well as the emaciation.

The vomiting, a very frequent symptom of affections of the pancreas, (*a*) furnishes but few facts bearing on this inquiry. We have to remark, however, that in a case of tubercles of the pancreas; Harles, in two cases of cancer; Laennec and Dr Henrot also, who communicated the case to us, have seen fat aliment provoke vomiting, while lean meat excited no such symptom. In a case by Leroux, though less explicit, it is stated that amylaceous substances, when given alone, were not rejected. Lastly, are we to consider as fat that substance, sometimes concrete and of an albuminous appearance, which Tacheron observed in the food vomited up by a woman, sixty-four years of age, suffering from cancer of the pancreas?

Such are the facts. As to their interpretation, that is subject to the objections which, in order to avoid repetition, we shall speak of in the next article.

The fæces have been more frequently examined, and we have been able to collect thirty cases in which the presence of fat has been noticed. This relative abundance of materials obliges us to treat this subject with some degree of detail. Fabricius Hildanus (1641) saw a patient with colic void a fat, white matter, contained in thick pellicles, and divided in small fragments. The patient recovered. Tulpius (1652) saw a woman, who was slender and often ill, void every day for more than fifteen months a great quantity of yellowish fat, floating in fæcal matters, that burned in the fire, and became solid when exposed to cold. Another of his patients, who died in a state of marasmus, voided fat both from the intestine and the bladder. Mæbius (1653) mentions the daily voidance of fat by a woman who died in a state of marasmus. Moellenbroch (1571) had a patient who for two years voided, *per anum*, a matter similar to beef-fat, and died also in a state of marasmus. Clauderius, Lentilius, Albrecht, Shalport van der Viel, also observed the presence of fat matters in the fæces. In a man affected with icterus, says Haller, the fæces were white, and covered with fat destitute of the fluid that should have dissolved it. After voiding a calculus *per anum*, the fæces ceased to contain fat.—William Scott saw a woman, twenty-five years of age, who suffered from pains in the stomach and violent attacks of colic. This person for three weeks brought away, with her stools, a great quantity of fatty matters that took fire when thrown on burning coals. A man of forty, according to Arnott, voided with his excrements a whitish, greasy substance, composed of small globules that melted with heat.—Turner sent to the College of Physicians of London several fatty concretions in form and size resembling blanched almonds, which had been voided from the intestine in a solid state. This patient, who was young and hysterical, took purgatives and for a week brought away each day from four to eight of these bodies, after which they did not reappear. Babington relates the history of a lady who had all the symptoms of biliary calculi. She took two or three ounces of olive oil; and there were then discovered in the fæces globular concretions of the size of grape-stones, slightly transparent, that could be cut like wax, and that melted with heat These substances were examined by Brandes, who considered them a composition of oil and intestinal mucus. A child of tender age, meagre and subject to jaundice, voided, at intervals of some days, an ounce or two of liquid fat that became solid on exposure to the air. He found it composed of olcine, stearine, and a yellow matter.—Kuntzmann's icteric patient, during thirteen years, voided without pain, and at different intervals, a fat fluid matter, the quantity of which was increased by the use of meat. At the autopsy, the pancreas was found indurated and its excretory duct obliterated; and there was softening of the intestinal mucous membrane. Hufeland, in whose journal this case appears, proposes to give to these fatty dejections the name of *stearrhœa*.—Pearson saw a poor woman whose evacuations were fatty; she had diarrhœa usually, with great pain, when she went to stool. The fæces were pale and odourless. She voided every day about two ounces of fat and an ounce of oil; but the quantity of this last was variable. At the autopsy no sort of lesion was found in the digestive organs: the liver was sound, fat, and pale; and the gall-bladder contained a fat, thickened mucus, scarcely inflammable. In a woman attacked with disease of the liver, and who died in a marasmic state, the same observer remarked in the evacuations a concrete matter of a fatty appearance, but without any colour from bile. Oil also passed from the intestine, and very soon became solid. It burned away in the fire. When mixed with an alkali, it formed soap.—Prout relates that a young woman, some months before her death, voided a great quantity of a fat material with her stools. The cæcum was much thickened, and the mucous membrane of a considerable portion of the intestine ulcerated. The rest of the abdominal viscera were sound.—Bright relates the following:—In September, 1847, a man, forty-nine years of age, who was diabetic, began to void per anum a great quantity of fatty matter. This evacuation followed that of the excrements. There was a suspension for eight days, after which it reappeared. This man died three weeks after in a state of marasmus. A scirrhus of the head of the pancreas obliterated the orifice of the biliary and pancreatic ducts.—An icteric woman, fifty years of age, voided with her stools, which were colourless, small, round, fatty masses, somewhat larger than peas. Bright ascribed them to a dose of castor oil which she had taken; but she affirmed that the same thing had occurred before taking any oil. She died six weeks afterwards. The pancreas was cancerous throughout. The ductus choledocus was still permeable.—A young woman, twenty-one years of age, whom Bright saw in 1831, died six days after she came to the hospital. There were, in her clay-coloured stools, pellicles of fat. Two fungoid tumours occupied the pancreas—the one the head, the other the body. There was stricture of the ductus choledocus at its insertion into the duodenum.—Lloyd, quoted by Elliotson, observed in the fæces of an icteric man, of forty-eight years, a greasy substance, of a deep yellow colour and nearly fluid consistence. This matter floated on the surface of water and became solid, but melted with heat and burned with a blue flame. Sometimes it contained a mixture of fæcal matters: but these last were usually distinct. When this substance was mixed with fæcal matters, these were usually of a deeper colour; when it was not present, the stools were pale-coloured like pipeclay. This phenomenon was noticed for seven weeks, but disappeared a week before death. Scirrhus of the duodenum and of the head of pancreas obliterated the duodenal orifice of the pancreatic and biliary ducts.—In Elliotson's patient, a man forty-five years of age, the stools, which were voided with pain, were often of a pale colour, and showed a liquid oil that became solid on exposure to the air, and burned when thrown into the fire. The patient continued to void these matters till he died. They were sometimes absent, or again flowed away involuntarily in great quantity. He died in a state of marasmus. All the

(*a*) It is only necessary to look into practical authors to be convinced that vomiting is not a symptom peculiar to any affection within the abdomen, but common to them all, not excluding the kidneys and pelvic viscera.—Translator.

organs were sound; the gall-bladder was full of thickened bile, and the pancreatic duct and its larger branches were found filled with white calculi.—In a man who had been ill for a long while, and whose alvine evacuations contained no bile, Gross, during several months, ascertained the presence of fat. The patient had about ten motions daily, and daily voided at least a half-pound of this substance, but only when he ate rich broth, or meat fried in fat. When he refrained from these, the appearance of the evacuations became charged in twenty-four hours, but again became fat when he took fat aliment. Five months before death, the patient became icteric. At the autopsy, the pancreas was found converted into a cyst which contained calculi, by which the pancreatic duct opening into the duodenum was completely obliterated.—A patient observed by Lassana had copious salivation, weight at the epigastrium, eructations, and constipation. The fæces contained yellowish particles similar to solid fat, which became more abundant after taking a purgative. The patient recovered.—In the 'Lancet,' Clark has published the following. A woman, fifty-seven years of age, had for some years had symptoms of hepatic colic. In December, 1850, a fat matter like butter was noticed on the surface of the urine. A more attentive examination showed that the fæces, which were without colour, contained it also; and that the presence of this substance in the urine was owing to its escape from the rectum—an occurrence of which the patient was not conscious, but which happened every time she made water, though there was not at the same time any excrement voided. Every day she passed 3 or 4 ounces of this fat substance, and 8 or 9 at a later period. These fatty evacuations were not interrupted by medicine, or by any modification of regimen. The pancreatic duct was found entirely obliterated, near its duodenal insertion, by a rough calcareous substance; the liver showed commencing cirrhosis, and the ductus choledocus, too, was obliterated.—A child, six years of age, seen by M. de la Tremblaye, for about eighteen months had the following symptoms: loss of appetite; vomiting of food, bile, and mucosities; ptyalism; rapid emaciation; constipation; and for the last eight days of life, diarrhœa. The solid fæces were here and there more or less covered with a yellowish-white pellicle resembling solid fat. The diarrhœic evacuations often resembled oil with which fæces had been mixed; but at other times the semi-liquid portions were covered with a transparent matter which the liver imbibed without being tinged by it. The lungs showed traces of chronic inflammation; so likewise the stomach and duodenum, of which the tunics, especially the muscular, were hypertrophied. The liver was perfectly sound.—In a case of cancer of the pancreas communicated by M. Roques to the Medical Society of Observation, the patient was icteric, and had diarrhœa alternating with constipation. The stools, which were not examined sufficiently often owing to the insufficient diagnosis, contained greasy matters.

Tulpius and Clark have noted the presence of a fatty matter in the urine; but the observation of the latter enabled him to account for this peculiarity: the fat escaped by the anus during the emission of urine, but without being perceived by the patient, by which he was deceived—a cause of error which it is sufficient to notice.

(To be continued.)

Statistics of Lunacy. — Late statistical returns show that in Belgium there are at present 51 lunatic asylums: 6 in the province of Antwerp (one of them the colony of Gheel), 11 in Brabant, 6 in Western Flanders, 16 in Eastern Flanders, 6 in Hainaut, 4 in Liege, and 2 in Limburg. The number of lunatics in Belgium is 4,907, which is 1 in every 920 of the population.

CASES OF PLACENTA PRÆVIA,

Communicated by EBENEZER FLEMING, M.D., M.R.C.S. Edin.

Two case of placenta prævia having occurred in my practice during the last few weeks, I have pleasure in furnishing you with the particulars.

Case 1.—September 17, 1860.—Requested this morning, at one o'clock, to attend Mrs A——, Shenchan street, Stranraer, who has had several children. On my way to the house, was informed by her husband that she was in an alarming state from a flow of blood of several hours' continuance. I found she had been flooding to a considerable amount; but as countenance and pulse were good, I spoke to her encouragingly.

On making an examination, I found the vagina filled with large, loose coagula; the os uteri dilated to the size of a shilling. The placenta partially presented, and adhered to the surface of the uterus behind the inferior margin of the os. The head also presented.

I plugged the vagina firmly with strips of soft rag saturated with cold water; and as there was no farther hæmorrhage, and the pains very feeble, I left the house, enjoining the attendant strictly to send for me if the flooding returned.

Visited her at eight o'clock. — No more flooding; pains feeble, and recurring at long intervals; no progress in the dilatation of the os.

Twelve o'clock.—Pains more frequent; some flooding; the os dilated to the size of a crown-piece; a part of the placenta exposed.

I ruptured the membranes, which at once had the effect of causing the head to exert mechanical pressure on the open vessels; no additional hæmorrhage for an hour, when the pains became very severe, and were accompanied by flooding, which ceased as the head occupied the cavity of the pelvis. She was naturally delivered of a strong, well-formed male child at two o'clock p.m.

The placenta came away immediately afterwards, and the uterus contracted firmly; but as the patient felt weak and exhausted, I administered a few drops of brandy. She recovered without an unfavourable symptom.

Case 2.—October 7, 1860.—Requested this morning, at eight o'clock, to attend Mrs F——, Stranraer; but as I had only returned a short time before from a long, fatiguing country visit, I desired the messenger to get some other person. Not having seen him, I heard no particulars of the case, nor thought of it again until I was summoned on the evening of same day, at six o'clock. I was now informed that she had been flooding since the preceding evening, and that she had only reached the seventh month of gestation.

I found her in a very anæmic condition from the excessive and long-continued loss of blood, which had saturated the bed-clothes, and formed a large pool on the floor. The countenance was anxious, and the pulse upwards of 120. Vaginal examination revealed complete placental presentation; os uteri considerably dilated, and very dilatable. The case was altogether so unpromising, that I plugged the vagina *pro tem.*, administered some brandy-and-water, and requested the assistance of my friend Dr Orgill, a very dexterous and skilful obstetrician, which was promptly and willingly accorded. We decided on separating the placenta in the first instance, and afterwards proceed as the circumstances of the case might demand. I accordingly introduced the greater part of the thumb and fingers of left hand into the uterus, and commenced the process of separation of the placenta from its inferior or posterior surface (from the position she was occupying). I effected this in a short time and without difficulty, and had the satisfaction soon of finding the membranes protrude, but could not ascertain the presentation; so I ruptured the membranes, passed my hand into the cavity of the uterus, and secured a foot, which I brought into the vagina. No difficulty was experienced in completing the delivery of a small female child, still-born.

On applying my hand over the abdomen to ascertain if the uterus was contracting properly, found it large, and expressed an opinion that there was another fœtus. Examination per vaginam verified the diagnosis. I again ruptured the membranes, and passed my hand into the cavity and secured a foot, which I brought down, and soon completed the delivery of a second small-formed female child, still-born.

A portion of the placenta was still adherent: this I gently separated, and on removal we found the umbilical cords inserted into a common placenta.

The uterus contracted naturally, and there was no subsequent hæmorrhage; but brandy was required, in small quantities, to raise the vital powers.

8th.—Still weak, on the whole progressing favourably; has made water; lochia sparing in quantity; slept well; no abdominal tenderness.

Her recovery was rapid, considering her perilous state. I prescribed tinct. sesquichlor. ferri, twenty-five drops in a little water, thrice daily —to be persevered in for some time.

Remarks on Case 2.—I do not recollect of reading or hearing of a case of placenta prævia complicated with twins. The complication was unfavourable, in so far as the depressing results of a second delivery had to be gone through, but favourable from the ease with which the delivery in each case was effected.

I was interested to know the exact position of the second placenta, but it was one common to both, as I have already stated.

The iron seemed to have an admirable effect in expediting convalescence.

Stranraer, Wigtonshire, Oct. 30.

THE SPIRIT OF THE PERIODICALS.

The 'Lancet' opens with a Lecture by Dr Brinton, introductory to the Course of Physiology at St Thomas's Hospital. We extract the following admirable passages:

"The word Physiology, then, must be taken conventionally as meaning 'the science of Life.' But what *is* Life?

"And here it must frankly be confessed that not only can we frame no definition, but that we have no knowledge. None, that is, sufficiently exhaustive or accurate, to call up any specific and fixed idea; much less an idea which, like the idea of a triangle, we can accurately reduce to words. In this respect, the embarrassment which thus meets us on the very threshold of our subject, does but, as you will find hereafter, forewarn you of difficulties which recur at every step of its study. Words it is imperatively necessary for us to weigh carefully; to consider why they were first adopted, in what sense they are now used, and what defects are inherent to them. To know well, that is to say, what they stand for. But we must beware of expecting them to describe, much more to define, the various objects to which they are applied; or we shall assuredly illustrate the second alternative of that Baconian adage, which says of them, 'words are the counters of wise men, but the money of fools.'

"Postpone, then, I would say to each and all of you, postpone for the present to substitute any plausible, but shallow, definition for that complex indefinable notion of Life which your own experience and observation must have already given you. Or seek after such a definition, if you seek it at all, not at the beginning, but at the end, of this course. Look upon it, not as a scale ready beforehand, to which you are to refer the various details of organization which we shall study; but rather as the end and conclusion of the whole matter. Try, if you must, to infer it from its innumerable phenomena; but do *not* try to dwarf these, or their vast sum, to any anthropomorphous standard; or to mutilate them on the Procrustean bed of our human ignorance and prejudice. Thus patiently waited for, no fear but that this great mystery of Life will be sought after by us in a spirit of modesty and of reverence. Find it we shall not. But even if we only see it, as it is permitted to us to recognise so many other things; even if all the light which science has hitherto brought into a focus only shows us Life as though it were seen through a glass darkly—with dim, hazy outlines, vague alike in form and dimensions—depend upon it the vision will not have been useless, or the toils by which it is attained unrewarded, or the delay prejudicial. For it will have taught you the attitude in which alone Nature is to be studied, and will

have saved you from many an error injurious not less to your future patients than to yourselves. Above all, it will have forced you, in your own education, to take in some degree the only path which has ever led Man to true knowledge or lasting success. The confession of ignorance is the first step in the search after knowledge; the rejection of imperfect hypotheses must precede the attainment of truth. And the history of Physiology, if read aright, teaches us not only to repel the idols of false doctrine, but to beware even of those treacherous allies whom knowledge has sometimes found in dominant ideas, themselves by no means wholly inaccurate. Life, for example, seems to be closely associated with the flux of bodily substance, the waste of the various tissues, the oxygenation of the bodily mass, the formation of carbonic acid, water, &c. But it would be rash therefore to assume that Life is identical with these processes, or equivalent to these products, respectively. On the contrary, looking merely to the scientific side of the question, we are no way in a position either to affirm or deny the possibility of a true conscious existence—an existence, that is, such as would be intelligible even to our limited comprehension—being created and maintained apart from them all.

"And this brings me to notice another consideration, which well illustrates the uselessness, not to say danger, of being fettered by definitions in the study we are now commencing. You are aware that this course of Anatomy and Physiology is understood to have an especial reference to the animal kingdom, and indeed to the human body. Hence to define the common boundary of Animal and Vegetable life, and to exclude the latter from consideration, might seem a necessary step towards opening up our subject.

"Here again, however, though it must not be understood that definitions are impossible, yet it can be asserted that it is not the beginner by whom such could be either used or appreciated. A rough outline we might easily draw. The possession of the faculties of sensation and motion; the consumption of oxygen to form carbonic acid; the evolution of a specific poison, urea; the maintenance of a more or less independent temperature; the reception of food into a digestive cavity;—these and other characters might be easily adduced as proper to the Animal, and the want of them to the Vegetable.

"But to what does all this amount? To little more, it may be suggested, than an elaboration of that distinction between the two kingdoms of Nature which even a child can observe and recognise. And you will find, as we go through the organs in detail, that each in succession offers us, either a plausible exception to the foregoing rules, or (what is equally embarrassing) such an increasing simplicity or suppression of organs as we proceed down the scale of animal life, that we are soon left in doubt as to their exact nature and products. The *Dionæa muscipula* catches flies—'like a Christian,' as the sailor said of his blaspheming parrot,—perhaps digests part of their juices. The *Mimosa pudica* almost fulfils the test of humanity propounded by Shylock, for when tickled, if it does not laugh, at any rate it curls up it feathers. Here are imitations of motion and sensation. The palm tree remains 20° or 30° below the temperature of the scorched earth around it in the desert. And while the phenomena of exchange of substance seem to offer a more uniform and valid distinction between the Animal and Vegetable, even these are sometimes open to doubt, and still more frequently fail to decide the question. There are traces, in many plants, of a systematic combination of oxygen, suggesting a formation of carbonic acid which is in striking contrast with that decomposition of carbonic acid, by virtue of which they restore oxygen to the surrounding air. While, to say nothing of the arbitrary and imperfect data on which, in many of the lower forms of animal life, our nomenclature of organs is often based—how is our chemistry to appreciate the urea, for instance, excreted by an animalcule of almost inconceivable minuteness? It is therefore scarcely to be wondered at if we find that, in the case of some of the simpler organisations, there is still a difficulty in determining whether they belong to the Animal or to the Vegetable kingdom.

"Animal and human physiology we shall not affect to distinguish, save in so far as we shall naturally lay greater stress, in the main, on the creatures whose structures offer the closest similitude to, or the best contrast with, those of Man. The human subject is, as it were, our standard of comparison, as well as the climax of our study. And only in the degree in which the organs of other animals foreshadow or indicate the uses of similar organs in Man, shall we have to notice those details, the fuller and more scientific consideration of which is remitted to the lectures on Comparative Anatomy.

"And I think it is no fanciful antithesis which further suggests itself as the result of comparing those two aspects of Physiology on which the Medical Physiologist, and the Anatomist in the wider sense of this word, respectively have to dwell. The former, specially concerned with structure and organisation, has for his object chiefly to determine the office of the several organs he successively studies: a procedure which finds its closest parallel, as well as its most important application, in the effect of those lesions of their tissues which are connected with the various diseases he attempts to relieve. Organisation, its development, its uses, the harmonious results of its perfection, the disturbance of health produced by its deterioration or decay, and the death which results from its destruction—these are naturally the chief objects of *his* consideration. The latter—especially in the last few years, which have revealed so much respecting the structure of the lower forms of animal life—would seem to be gradually arriving at conclusions which at first sight appear almost incompatible with those of his Medical colleague. Were it asked—'What are the most striking results of modern research in Comparative Anatomy?' it might be unhesitatingly answered—'The extraordinary modifications of late gradually disclosed in functions hitherto presumed to be uniform; and the lower level thus assigned to organs as a whole: or rather—what is more accurate—the lofty but inscrutable share assigned to functions as distinguishable from structures. Generation, for example, is shown to be no single special process, common to the whole animal series; but a function which, in different creatures, offers the most extraordinary—I had almost said contradictory—phenomena. While the structures concerned in respiration, locomotion, and innervation, offer such strange contrasts of development in some of the lower and higher animals, that we can hardly escape the alternative: either that many functions may be regarded as essentially independent of all structure whatever (a proposition which, I am aware, almost involves a contradiction in terms); or that, at any rate, the very simplest and most structureless tissue, to our existing means of observation, may yet possess everything necessary to effect a function which, in a higher quality or greater quantity of action, requires all the aids the most elaborate organisation can confer. An animal which swims, feels, breathes, digests, absorbs, secretes, aye even propagates, at all points of its surface indifferently; and thus fuses, as it were, all the several functions of Life into a single purpose, executed by a single tissue, in the transparent membranous expanse of which the highest powers of our best microscopes fail to detect any differentiation of structure whatever; offers, so to speak, a warning against presumption—a silent sermon on the inscrutable mystery of Life, and the limited extent of our knowledge—which we shall do well to carry with us through all our physiological studies, even to the very bed-sides of those sufferers whom we must sometimes vainly attempt to heal.

"Confessing, however, the imperfectness of our present means of information, and owning the probability that the several phenomena of Life, as well as their great total, offer much which we cannot at present regard as the mere result or equivalent of histological details, we yet fasten our attention on the structure and office of the organs of the human body. And in so doing, we not merely obey a law of mental progress—proceeding from the known to the unknown, from that which we have, to that which we have not, seen—but we specially fit ourselves for the practice of medicine and surgery; for the relief, that is to say, of the various derangements and injuries to which the body, inside and outside, is subject.

"I am almost ashamed to dilate upon this statement, as though it were questionable in itself, or as though your incapacity to appreciate it required its repetition and enforcement. Nevertheless, since it has been questioned, and that, too, by some holding no mean position in our profession; and since not only the general usefulness of this course, but the whole of its details are (I hope and believe) dictated by the relations of Physiology to the healing art; you must bear with me for a few minutes while I briefly point out some of these relations.

"Of these, the most immediate and irrefragable is that suggested by the very nature and seat of all diseases and injuries. If any one offered to mend your watch, candidly owning that he had never opened such an instrument, and was perfectly ignorant of its construction, he would exactly parallel the imposture of Physic not founded on Physiology. If he said, 'This mysterious derangement of your watch is a separate entity, a something added to the original works, and, on the principle of *similia similibus curantur*, I propose to give it an additional knock to that which has, let us suppose, deranged it; or to break, if I can, another spring or wheel, to remedy that already injured,—'he would be describable as a homœopath. If, on the contrary, he said, 'In derangements of this kind, forcing into the interior of the watch a very long and strong lever, and giving it a good wrench, has been sometimes known to rectify the mischief; or cutting away one-half of the main-spring, has allowed the other to propel the whole apparatus,'—he would rank as an empiric—what many would still call 'a sound practical man of the old school:" a school useful and venerable in the epoch in which it represented the existing acquisitions of medical knowledge,' but simly an anachronism in this. If, lastly, he asserted that 'a watch going right, and a watch going wrong, were governed by such very different laws of action, that the study of the one threw little or no light on the other,' I think you would not find much difficulty in dealing with a sophistry which, applied to the study of medicine, would end in exalting the pedantry of the charnel-house into a system of Physic; in affecting to teach us how to cure disease by looking at what is incurable, and to preserve Life by gazing upon the poor putrid relics of what was formerly its envelope.

"Physiology, then, we study as being the very basis of the healing art. It alone teaches us what is disease: shows us how such slight and casual derangements of the corporeal functions as are too minute or transient to attract ordinary notice, have only to increase in degree, to claim our attention as downright maladies. It points out, in language which he who runs may read, that most of our diseases are thus founded upon our own ignorance or carelessness; that they are often the inevitable results of a systematic disobedience of the laws of Nature, either by individuals or societies. Nay more, it offers us some analogical hints with respect to that awful and mysterious subject, the origin of evil; and 'justifies the ways of God to men' in so far as concerns many of even the most painful and dangerous maladies, by showing unequivocally how the very capacities of growth and development, of resistance to injury and reparation of its effects, are inherently connected with the possibilities of disease; so that the same arrangements which are constantly healing incisions, and reuniting fractures, occasionally permit pleurisy and pericarditis. And lastly, it regulates, weighs, and dictates all those appliances by which we have to attempt the cure of sickness, the relief of suffering, the restoration of health, and the prevention of death."

The Author then shows the dangers comprised in a reliance upon the phrases "a natural history of disease," the *vis medicatrix naturæ*, and the principles of the expectant method of treatment. Homœopathy also comes in for a share of his criticism.

Mr Henry James contributes to the same journal a report of *Two Cases of Concealed Accidental Uterine Hæmorrhage*. We quote them:

"*Case* 1.—On the 26th of March, 1853, at half-past six a.m., I was requested to attend upon Mrs M——. This patient had borne three children previously, and was now at full term in her fourth pregnancy. Her husband informed me

that she had not been suffering with labour pains, but that she had fainted, and he had left her in a very weak state. I immediately accompanied him, and found her to be a very delicate woman, of a strumous habit: her countenance was pallid, anxious, and sunken; she was very restless, her skin was bedewed with a profuse perspiration, and her pulse was rapid and feeble. Although she was evidently greatly exhausted, there was no outward evidence of hæmorrhage; indeed, she assured me that she had lost no blood, and the nurse confirmed her statement. She had already taken some brandy, and I gave her more. She complained of intense abdominal pain, and I suspected that there might be rupture of the uterus. On placing my hand upon it, the sensation was less firm than usual; but I was satisfied the fœtus had not escaped from it, and therefore, if rupture had occurred, that it was only partial. Upon examination per vaginam, I found the os uteri to be already dilated to the size of a shilling, and in a very dilatable condition, the membranes unruptured, and the head presenting. My finger was unstained with blood, and the vagina and external parts were so flaccid as to present little obstruction to delivery being effected.

"I determined to endeavour to excite uterine action, and for this purpose I gave her seme of the tincture of secale. I now passed my finger through the os uteri, and round the neck, with a view to excite uterine action and to rupture the membranes. Immediately a gush of blood followed, which was so large in quantity that it both surprised me and made me fearful for the result. I now ruptured the membranes, and a considerable quantity of the liquor amnii escaped; contractile pain came on, expelling immense quantities of coagula, and I was delighted to find that my patient, instead of becoming fainter, was improving in her condition. The pains now followed rapidly, and a full-sized male child was born, and, though in a feeble state, it survived. The funis was entwined twice round the neck, but from its great length it did not interfere with the birth of the child.

"The uterus contracted well, expelling more coagula with the placenta. Upon making a careful examination of the placenta, I could not discover which portion of it had been detached from the uterus, or whence the hæmorrhage had proceeded.

"The patient's recovery was satisfactory in all respects, as she suffered only from those inconveniences which follow upon an excessive loss of bleed. No accident of any kind had occurred to account for her condition, and she has since had children without the supervention of any hæmerrhage.

"*Case* 2.—On the 28th of February, 1856, at four p.m., I was called to attend upon Mrs C——, a patient whom I had not before visited. I was informed that she was in her eighth month of pregnancy, and that she had suddenly lost a large quantity of blood. Upon visiting her, I found her restless and alarmed; her pulse was feeble, irregular, and intermittent; her countenance was very pallid, and her extremities were cold. She complained of pain in the abdomen, and had lost a considerable quantity of blood. She was a stout woman, of about the middle height, and of a very excitable and nervous temperament. I gave her some stimulants, and examined the condition of the uterus through the abdominal parietes. I found its condition to be normal; the vagina was full of coagulum, and bleed was still flowing freely; the os uteri was dilated to about the size of the tep of a wine-glass, the membranes were unruptured, and the head was presenting. I ruptured the membranes, and gave her some secale in brandy; the pains came on rapidly, and in twenty minutes a still female child was born, a large quantity of coagulum being expelled. After this my patient excited my fears, for she yawned, threw up her arms, and fainted. I feared she was dead, but she rallied from this state, and was then in such a restless condition, and so obstinate, that I experienced the greatest difficulty in getting her to take a sufficient quantity of nourishment and stimulant. Ice was freely applied, and the uterus contracted well and threw off the placenta. For several hours I continued to attend upon her, and she then rallied a little, and ultimately recovered after a protracted convalescence.

"Upon examining the placenta, I found that about one-third of it was covered by adherent coagulated blood, and this was the portion which was detached from the uterus, and the source of the hæmorrhage; and if it was separated upon the occasion of her using violent exertion, concealed hæmorrhage must have been going on for twenty-eight hours.

"She subsequently gave me the following account of herself: On the morning of the 27th she had some little trouble with her servant, which resulted in her using considerable effort to force the girl from the room. . Through the night she felt pain in the abdomen, and was very faint and sick On the following morning she felt so exhausted that she remained in bed, but she did not consider that the pain she was suffering from was labour pain. At half-past three in the afternoon of the 28th of February she was sitting in bed, when a sudden and enormous gush of blood occurred, which she at first thought must be the waters, but finding it to be blood I was sent for."

Dr Stephen Ward contributes some remarks on *Scurvy*, and Mr Broadbent a report of a *Case of Recovery after apparent Death from Chloroform*. The case is very interesting.

"Mary M——, admitted March 15, 1860, with obscure disease of the left knee-joint, of about four months' duration. She is twenty-three years of age, but looks thirty-three, spare, but not emaciated. Is suckling a baby nine months old. Treatment having had no effect in arresting the disease, it was decided to amputate the limb. For this purpose she was put on the operating-table on March 25th. Nothing unusual was observed in her expression; her pulse was about 120, rather feeble; heart sounds normal. About two drachms of chloroform was poured on lint, folded in a funnel shape. No struggling occurred during the inhalation. In two or three minutes the pulse was observed to become slower; but it was steady, and the respiration natural. Soon after she appeared insensible, and I was about to commence the operation, when she suddenly ceased to breathe, and the pulse could not be felt. Cold water was instantly thrown on her face, air freely admitted into the room, and artificial respiration kept up by alternately compressing and relaxing the chest. These measures were continued for a short time, but without success. The head fell on the chest, and the chin dropped—in fact, she appeared quite dead. As a last resource, in order to use artificial respiration more effectually, it was decided to open the trachea, and inflate the lungs through the wound. This was at first done with the mouth applied to the wound, and in about two minutes feeble inspiratory efforts took place, but ceased immediately when the artificial respiration was discontinued. A female catheter was now introduced into the trachea, and artificial respiration kept up through it. In a short time the natural respiratory efforts improved, and the wound in the throat commenced to bleed. After watching her closely for an hour and a half on the operating-table, and giving her three ounces of brandy, she was removed to a warm bed, and the wound brought together with plaster. She completely recovered from the effects of the chloroform; but the disease in the knee rapidly became worse, and she was anxious to have the limb removed. This was done on April 14th, chloroform being administered by means of Sibson's inhaler, if possible with greater care than before. During the operation, which was rather prolonged from the disease having extended further than was expected, she inhaled six drachms of chloroform, without any bad effect. She rallied from the operation very slowly, but afterwards progressed favourably until the stump was nearly healed, when the disease, which proved of a malignant nature, returned, and she died exhausted with repeated attacks of hæmorrhage on May 31st.

"*Autopsy, eighteen hours after death.*—Body very anæmic. Chest: Lungs healthy; pleura on the right side slightly adherent. Heart: Anterior surface of right ventricle very fatty, and the muscular wall very thin; left ventricle and valves healthy. Both ventricles contained yellowish coagula; auricles healthy. Abdomen: Stomach distended with gas; kidneys of a normal size, but their structure disorganised. The remaining organs healthy. The kidneys and muscular structure of the heart, when examined with the microscope, were found to be in an advanced state of fatty degeneration."

Mr Beale gives the following description of a *Monster* associated with maternal impressions:

"Mrs W——, aged twenty-eight years, tall, and well formed in figure, was attacked by a dog and bitten in the lip when advanced five months in pregnancy with her first child. The child was born dead, and presented the following deviations from the correct conformation:

"Head natural size, but very thick; broad and fleshy about the juncture with the shoulders. The under lip drawn in, and slightly puckered; the upper drawn up, and slanted off towards the alæ nasi. An opening, presenting the appearance of the entrance to the larynx, was seen on separating the lips, and occupied the cavity of the mouth. Two diminutive, shapeless growths, about three inches and a half long, supplied the place of arms, terminated by the outline of the tips of six fingers, arranged almost around a broad, flattened palm. The umbilical cord bulged out into a sac at about two inches from the navel, and was filled with a bloody-looking fluid. The thighs were extremely short, flat, and thick; the feet presenting the same appearances as the terminal part of the superior extremity, the heels touching the nates, and the whole limb not exceeding three inches and a half in length, and, seeming, as it were, to grow out of the pelvis. The anal aperture was situated in the upper part of the lumbar region. No examination with the scalpel was allowed.

"This patient has, after the lapse of eighteen months, been delivered of a similar malformation. She this time accounts for the mischief by being frightened by a man in the street who obtains his living by shuffling himself along on a piece of board strapped on wheels (he appears devoid of his lower extremities).

"The case is curious, inasmuch as the previous impression conveyed to the uterus has been retained and reproduced after a lapse of eighteen months, and argues that the impression may still reappear in future pregnancies. All the phenomena show an arrest of development, and of a lower type than generally when these arrests take place. Her husband is tall, healthy, and perfectly formed."

A Case of Phlegmonoid Erysipelas of the Head and Face without any constitutional symptom is reported by Dr J. D. Macgregor; and Mr Spratly describes a new form of *Instrument for Vaccinating*. It

"Consists of a small lancet-point of triangular shape, about the twentieth of an inch in length, the upper surface being formed by the base of the triangle, the under by the two sides and apex. The upper surface is carefully hollowed out both to the edges and point; this serves for the reception of a moderate quantity of lymph. On the under surface is a small guard, which projects from each of the two sides of the triangle, and which forms the under surface; this prevents the point entering the skin beyond a certain distance. It is mounted on a small steel stem, and inserted in an ivory handle, or may be made to fold up like an ordinary lancet. When about to be used, the excavated upper surface is filled with lymph, either from a fresh vesicle or from some preserved in Dr Husband's admirable capillary tubes, and inserted diagonally beneath the skin; this forms a little valvular wound, into which a minute drop of matter flows, and no more blood follows the operation than would be caused by puncturing the skin with a fine needle."

The inventor has used it in nearly 800 cases with success.

Dr M'Millan, of Friockheim, reports a case of *Rupture of the Liver*. We give it.

"The following case possesses so many points of practical interest, that I am induced to bring it under the notice of the Profession; and that the reader may have the whole case before him, I subjoin the report sent home to Scotland with the patient from the surgeon who attended him:—

"Wm. B——, aged twenty, was kicked by a horse on the 20th of April last, over the region of the liver, causing a considerable amount of inflammation, symptomatic with fever and jaundice, the fever and jaundice subsiding about the seventeenth day. As a sequel to this, ascites set in,

and has been very troublesome up to May 31st, when he left this place for Scotland. Treatment during the inflammatory stage—Antimonials, aperients with mercury, local bleeding, poultices and fomentations. Calomel and opium have been pushed, so as slightly to affect the mouth. During the dropsical symptoms, friction with mercurial ointment over the region of the liver, with diuretics, first of potass with spirit of nitrous ether, then sulphate of magnesia in the morning, with alterative doses of blue pill and digitalis. Now (May 31st) he takes spirit of juniper with digitalis, and mercurial ointment with iodine and powdered digitalis rubbed over the whole region of the abdomen twice a day. I have now recommended a change of air to his native country.

"I was called to take charge of the case on the 2nd of June, the patient having arrived from England the previous evening. I found the abdomen greatly enlarged, about the size of a woman at the full term of utero-gestation; it felt hard, and unlike any case of ascites I had ever seen. I applied hot fomentations to soothe the irritability caused by the enlargement of the abdomen, and gave anodynes to allay the systemic excitement resulting from so long a journey having been undergone in the patient's debilitated condition.

"June 3rd.—Has slept little, continually crying out, 'Oh, my belly!'—Twelve o'clock noon: A consultation on the case with Dr Guthrie, sen., of Brechin, when, after a careful examination, we came to the conclusion that it was not ascites, as our English friend had concluded, but that the enlargement was the result of effusion consequent on rupture of the liver, which was greatly enlarged, and gave great pain on being pressed. The bowels we found pushed into the left iliac region, and the whole abdominal cavity occupied with fluid. Such being the opinion arrived at, to operate was clearly our duty; accordingly it was agreed that we should operate next day. Hot fomentations were continued; an aperient and an anodyne were given in the evening.

"4th.—There were present Dr Guthrie, sen., Dr J. Guthrie, jun., and myself, when, having bandaged the abdomen as in the operation for ovarian dropsy, and placed the patient in the lithotomy position, Dr Guthrie, sen., made an incision about an inch below the umbilicus, and introduced a trocar and cannula. We drew off 324 fluid ounces of a grumous liquid, composed of blood, bile, &c., which had a most offensive smell. Pieces of adhesive plaster were then strapped over the wound, and the whole abdomen very firmly bandaged. A sedative mixture was then given, and during the evening our patient had some sleep, and on awakening he partook of a little food.

"5th.—Feels more comfortable this morning, and took some breakfast. Complained of some griping pains in the abdomen, for which an anodyne mixture was given.

"I omit giving here the daily state I found him in, as it is of little moment; but he continued gradually to improve and gather strength till June 17th, when he went out with me, and took a walk for nearly a quarter of a mile; and on the 18th he went alone to the other end of the village. About a week afterwards I recommended a short ride on horseback. He smiled when I proposed it; but on my offering him my horse, he mounted, and rode fully a mile, trotting some part of the way.

"Sept. 4th.—From the 5th ultimo there has been gradual improvement, and now he is fully convalescent, being engaged in harvest operations in the field with his father."

An Analysis of the *Water of Ben Rhydding*, near Otley, Yorkshire, is reported by Dr Sheridan Muspratt. It is almost entirely a silicate and calcareous sulphate. Dr Finlay, of Bothwell, describes a case of *Poisoning by an Overdose of Opium in a Child.*

The 'Medical Times and Gazette' contains a Report of a Lecture, by Mr T. Spencer Wells, on the *Turkish and Roman Bath.* The lecture is illustrated with drawings. We make the annexed extracts:

"Let me now describe to you the baths of ancient Rome, premising that you are to lay aside the impression that a bath must be a water bath, and remember that it may be an air bath as well. The Lacedæmonians seem to have been the first to put this distinction into practice. The Greeks, from the earliest period of their history, bathed both in salt and fresh water, and in the *Thermæ*, or natural warm springs. They also took warm and cold baths in succession, taking a warm bath at home after returning from bathing in the sea, or plunging into cold water after a warm bath. The Spartans, who looked upon warm bathing as effeminate and enervating, and practised daily bathing in their rivers, used the dry sweating bath in a room heated by a stove, called after them by the Romans, *Laconicum*. The Athenians had public baths, *Loutrones*, as part of the gymnasia; but these seem to have been water, not air baths, for the λουτήρ or λουτήριον was a large round or oval basin, in which the bathers sat or stood. The Romans seemed to have used the warm-water baths long before the Spartan Laconicum was introduced, and the latter was first adopted in private houses; but by the time of Cicero public and private baths, both of water and air, had become general and magnificent. In one of Cicero's letters to his brother, he tells him that he has directed the *assa* (vapour bath) to be moved to the opposite corner of the *apodyterium* (undressing room) because the *vaporarium* (flue) was ill-placed. Cicero also speaks of the baths open to the public on the payment of a quadrant, the smallest piece of coined money extant. The practice of bathing in cold water after the excessive perspiration of the hot-air bath seems, according to Pliny, to have been introduced by Musa, the Physician to Augustus, who derived so much benefit from it that it became quite the fashion. Musa was afterwards accused of causing the death of Marcellus by the same treatment. In the First Book of Celsus you will find a great deal said about the succession of warm, tepid, and cold bathing. Galen advised first the hot-air (ἀέρι θερμῷ), then the warm water, then the cold, and afterwards friction and anointing with oil. Celsus prescribes first the Tepidarium, then the Calidarium; then to have a quantity of warm, tepid, and cold water in succession, poured over the head and body. Afterwards the body was to be well scraped with the *strigil*, then rubbed dry and anointed. This practice, introduced into Turkey by the Romans of the Lower Empire, is that still universal in the East, and is now being revived here. . . . . .

"However varied in size or detail, the essential parts of the bath are ever the same: a chamber filled with heated dry air, or Sudatorium; a cooler but still warm chamber, or Tepidarium; and a third of the temperature of the outer air, or Frigidarium, with attendants who cleanse the skin, rub the surface of the body, press or knead the muscles, and apply douches of water of various temperatures. All this has been described over and over again by travellers, and every guide-book contains some account more or less interesting, according to the ability of the writer. But no one attempted of late to introduce the Oriental Bath into this country, until Mr Urquhart, by his writings and lectures, and personal example for some years past, has led to a revival which is rapidly bringing it to the position of a national institution, and we are likely before very long to see something like the luxury and splendour of the Imperial Roman edifices arise again. I said of *late*, because in 1679 some Turkish merchants opened a Turkish bath in Bagnio court, Newgate street. It had a domed roof, marble steps, and walls of Dutch tiles. The court has been called Bath street since 1843. In the 'Spectator' another Baguio in Chancery lane is alluded to. The Hummums in Covent garden was formerly a Turkish bath, and took its name from the Arabic *Hammam*, a bath. For a hundred years or more the bath has been neglected here, but at length fine buildings, erected at a cost of several thousand pounds each, may already be seen in or near Cork and Dublin, and in other parts of Ireland; and smaller, but still considerable, establishments are in full force in Manchester, and several other large towns in the North. In London, the first public bath was opened by Mr Evans, in Bell street, Edgware road. He has lately opened another and larger establishment in Golden square. There is also a large establishment in Palace street, Pimlico. Mr Mahomed has one in Somerset street. All these I have seen, and I have always found them either crowded or well filled with bathers. Others are heard of as springing up in all directions to supply an ever-increasing demand, and many gentlemen are erecting them in their own houses. I need not repeat, therefore, that it is high time you should make yourselves masters of the subject. . . . . .

"At the public baths you first enter the tepidarium. Here the air being slightly moistened, and the temperature at 120°, perspiration is very soon induced, and without any feeling of heat or fulness of head, or oppression of breathing. When perspiration has commenced you pass into the sudatorium, where the air is drier and the temperature 160°. Remaining here some time, occasionally passing to the tepidarium for a few minutes and back again, very free perspiration is kept up. It stands out on the skin in clear drops, and runs down in dripping streams. This is encouraged by drinking copious draughts of cold water, and then one is ready for the shampooing. In Turkey and Egypt this process is performed in the hot room, as I am told it is in some of the baths in Ireland and the North of England; but in the London baths it is done in the outer room, or tepidarium. The bather reclines while an attendant rubs and kneads limbs and body until all superfluous epidermis and a quantity of sebaceous matter is thoroughly cleansed off, and the circulation in the skin becomes very free; the rosy tint of the capillary plexus glowing through the transparent covering, the white marks traced by the pressure of the fingers being instantly reddened by the returning rush of the arterial current. I remember Mr Liston, in his latter days, testing the freedom of his capillary circulation by pressing the end of one or other of his nails, and watching the return of the blood to the capillary plexus beneath the nail. An experienced eye can generally detect a 'companion' in the bath by the rosy tint and free circulation in the skin, which is very different in the uninitiated. Of course you must make allowance for the natural difference between fair and dark people; but those who do use the bath habitually are certainly remarkable for clearness and ruddiness of complexion and of the skin generally. Opaque epidermis is removed; choked-up sebaceous follicles are cleared; the sweat-ducts become quite free; the subcutaneous cellular tissue becomes pliant, admitting that free motion of the skin on the subjacent tissues which is the reverse of what jockeys call 'hide-bound;' superfluous fat disappears; the elastic and contractile structures of the skin regain their normal properties, and the ultimate nervous fibrils their normal sensibility.

"One of the most common objections raised to the bath is the fear that the transition from a heated room to the open air may give cold. But experience proves that this fear is groundless, provided ordinary precautions be taken; and a little reflection will show you *why* it is groundless. The skin of the face, which we habitually leave uncovered and exposed to rapid alternations of heat and cold, receives no unpleasant impression from a current of cold air after leaving a hot room. But the rest of the body is kept covered up from the light and air, and unnaturally heated, and, therefore, loses its normal sensibility and its natural power of supporting changes of temperature without discomfort or injury. The habitual use of the bath tends to restore the normal properties of the skin. When the body is thoroughly heated, it is enabled to resist cold; when perspiration is going on freely, a stream of cold water is only a pleasant mode of producing contraction of the structures of the dermis. Any feeling of chilliness passes off at once on returning for a few minutes to the hot room; and then, as perspiration again commences, the bather may pass to the cooling-room with perfect impunity, and with a skin which with each succeeding trial becomes more and more habituated to alternations of temperature,—in other words, with unnatural susceptibility to cold corrected. Something of the same sort might be said of the mucous membranes of the air-passages, so that persons who have been subject to colds or bronchitis on the slightest exposure to a draught of cold air do not suffer at all from such exposure after the use of the bath. . . . . .

"We may regard, then, this purification of the blood by the elimination of the watery, saline, organic, and fatty excretions of the sudoriferous

(Continued at page 310.)

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Untamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

THE MEDICAL CIRCULAR.

WEDNESDAY, NOVEMBER 7, 1860.

THE CASE OF THOMAS THE BONE-SETTER.

Our Courts of Law are becoming arenas for the discussion of difficult Medical problems. Many of the proceedings of these Courts are as interesting as, and perhaps more valuable than, the reports of a debate at a Medical Society. The witnesses read up the subject, consider thoroughly all probable modes by which an ingenious Counsel may seek to perplex their judgment, strengthen all the weak points of their opinion, synthetically construct the known facts into a model case, and, armed with ready answers to all possible questions, mount into the witness-box with confidence, and, perhaps, also with the secret ambition of making a conspicuous figure in the report in the next morning's paper. Each man, knowing that his professional character will be either aggrandised or discredited by his bearing in the witness-box, is naturally anxious that the view he is prepared to maintain shall be as completely vindicated as possible by the facts; and thus it often happens that the same data are made the foundation of the most contradictory opinions. This is a circumstance that cannot be avoided. So long as Medicine shall have its problems, so long will they be liable to two interpretations. It will be these problems also that clever Counsel will be sure to seize upon for the purpose of exhibiting the uncertainty of Medical Science, and destroying the force of opposing evidence.

We, last week, reported an examination into a charge of manslaughter, brought against one Evan Thomas, a "bone-setter," who attended a boy suffering from an abscess of the thigh. Believing the bone to be fractured, the man put on splints, whereby, it was alleged, the purulent matter became absorbed into the system, and deposits took place, of which the boy subsequently died. The case was thus related:—On the 2nd of October, the deceased complained of pain in the knee, which he attributed to a blow inflicted by a younger brother. On the following Friday, the 5th, he became worse, and was seen by Dr Lambert, who, conceiving that an abscess was forming, ordered poultices of linseed meal to be applied, and the patient to be supported by good diet and a little wine. On the following day, some intelligent friend of the family suggested that the limb was fractured; and Mr Evan Thomas being the recognised bone-setter of the neighbourhood, the child was taken to his house. Thomas confirmed the opinion of the family's friend, and added that his fee for setting the bone would be 10s. It would be difficult to say that Evan Thomas was a mercenary man, but for the subsequent colloquy. The boy's father had only 5s. in his pocket, which he offered as an instalment of the fee. Thomas demurred; he seemed to think that 10s. exactly hit the value of his service, and that he could not afford to discount it by a day's delay. He therefore discreetly intimated that he gave "no trust." The father was distressed. Here was a man who declined to set his poor boy's fractured leg because he could not muster 5s. In his despair, he resolved to take the boy away in a cab. At this crisis, a friend in need stepped upon the scene and generously offered to contribute the required amount: the quack was now satisfied, and set to work upon the limb. What he did we are not accurately informed; but he went through the process of setting the bone, put on splints, and ordered the use of cold lotion. On Sunday the boy became worse; on Monday Dr Lambert was again sent for, declared that there was no fracture, and removed the apparatus. On the following day the child died.

The post-mortem examination showed that Dr Lambert was right, and Evan Thomas grossly and shamefully incapable of treating the simplest form of surgical disease. A large quantity of matter was found diffused among the muscles of the thigh and round the bone; the latter was not fractured. There were three distinct abscesses in the substance of the heart, and minute depositions of purulent matter studded the kidneys. The pericardium was, moreover, filled with turbid serum, with deposits of lymph on the heart's outer surface; the pleuræ were adherent, with effusion into the cavity. Dr Lambert considered that the cause of death was pyæmia, produced by the absorption of matter from the thigh, the absorption being accelerated by the bandaging of the part affected.

It was this opinion that was the subject of controversy before the Bench of Magistrates. Dr Lambert was supported by Dr Baylis, Mr C. Evans (Surgeon to the Birkenhead Hospital), and Mr J. Dowling; and opposed by Mr Hugh Owen Thomas, a qualified Surgeon, and the son of the person charged, who, however, does not appear to have expressed a clear opinion upon this particular subject; by Dr O'Donnell, who thought the heart was diseased at the time of the appearance of the first symptoms; by Dr Roberts, brother-in-law to the accused, who considered that the treatment had nothing to do with the result; by Mr Pope, formerly Surgeon of the Southern Hospital, who also believed that the treatment was not instrumental in inducing death; and by Dr Lodge, who thought that a diseased condition of the blood was necessary to produce pyæmia, and that it would be extremely difficult to say that pyæmia was induced by pressure in the case under consideration.

All the witnesses admitted the existence of pyæmia; they only differed on the point whether the pressure was the cause of this condition of the system. The theory of the nature and mode of production of pyæmia is not yet clear; its phenomena are still the subject of observation and experimental research. Whether the malady be caused by direct absorption of matter contained in an abscess; and if so, how the pus-globule gets through the walls of the capillaries; and why it does not do so on all occasions,—whether it be rather caused by the absorption of the serum of pus, whether it be not in reality a local inflammatory affection, or whether it be dependent upon the presence of a particular crasis of the blood itself, with many subordinate questions,—are topics of frequent discussion among Medical Practitioners. Until these points be determined, division of opinion must exist, and is, in fact, the necessary condition of inquiry. We shall not, therefore, set up Dr Lambert against Dr Lodge, or Mr Evans against Mr Pope; the pathological question upon which they disagree being one on which difference of opinion is allowable.

There can be no doubt, however, about this, that the child had been ignorantly and mistakenly treated; and it will be generally admitted that the tight bandaging of a limb in a suppurative state would be very likely to set up that irritative fever which would produce death, with most of the post-mortem appearances exhibited by this poor child. Theory apart, who can conscientiously say that the treatment was not likely to induce the constitutional disorder and local inflammations and effusions reported in this case?

The prisoner was committed for trial, a decision that was unavoidable. It will be a lesson, we hope, to other impostors who abuse the confidence and imperil the health of the public by their audacious and fraudulent pretensions.

GIFTS TO GARIBALDI. — An Englishman, Mr Briggs, merchant, of Manchester, has sent to General Garibaldi 400 knapsacks, tents, and other valuable material, asking only in return an autograph of the General. Lady Paumure sent, some time since, 500 oz. of quinine.

A CHIRURGICAL BEQUEST. — M. Lenoir, an eminent French surgeon, who died lately at Paris, has directed, by his will, that all his surgical instruments should be given to that house-surgeon of the Paris Hospital who shall, this year, stand first in the examinations for that office.

SUMMARY OF THE WEEK.

SOLDIERS, PHILOSOPHERS, AND BEARDS.

The General Order of General Pennefather, requiring the soldiers at Aldershott to trim their beards, has fallen like a live shell in the camp. Even civilians sympathise with military agonies, and every several hair on birsute cheeks bristles with wrath at the thought of mutilation. This is a very serious business. One of our contemporaries assures us that the vitality and muscular vigour of a man depends upon the length of his beard. Perhaps the Rev. C. Kingsley took the hint for his teachings about muscular Christianity from the prevalence of beards, these capillary appendages symbolising both wisdom and strength. Our contemporary cites Bichat's opinion in support of this view. Bichat, indeed, illustrates his position by referring to the admitted vigour of the ancients, who wore long beards, and those monkish people who were addicted to the same practice. Admirable Bichat! We always believed that these cloistered gentry were types of physical energy,—far superior, indeed, to your Cœur-de-Lions, and Godfreys, and Tancreds, who only wore a paltry and unmeaning moustache. There can be no doubt about it, that the bearded monks, the schoolmen and the astrologers, were the real heroes of the middle ages—the veritable warriors who wielded terrible battle-axes, wore steel armour, slept out on cold nights, forded rivers breast-high, scaled lofty walls—or if they did not, they ought to have done it, and the entire life of the middle ages was a physiological error. If General Pennefather's Order be enforced, what will the civilians do—certain Doctors included? A quiet man, now-a-days, may easily pass himself off for a Crimean or Indian hero by letting his beard grow: the hairy skin suffices to make many a dull animal pass for a true lion, if he only have the prudence to hold his tongue; but a sentence against military beards is the doom of civil beards too, and then it will be all up with the dignity of human nature. We really pity the civilians—philosophers especially! We were rapidly breeding a race of geniuses who, in a few years, would put all the Solons of antiquity to the blush—if they were ever able to perform that physiological experiment—but General Pennefather's Order comes like a chilling blight upon our prospects. There might be some sense in docking the length of a rifleman's beard, as it might come inconveniently in the way of his firelock, which might go off with unexpected celerity, his beard for the nonce playing the part of a hair-trigger; but philosophers don't fire guns, or, at most, pop-guns only, charged with paper pellets—so that we do not see why they should not continue to wear their beards. The beard is undoubtedly a sign of mental and physical vigour, as our contemporary asserts. The Schah of Persia has the finest beard in the world, and unquestionably he is the wisest man in it, for he deigns not to speak to anybody, nor allows anybody to speak to him; and a man who can succeed in concealing his ignorance is no fool. Now the beard helps a man to do this very effectually. On the other hand, among the monarchs of England there is only one distinguished with a beard—the unfortunate Charles I. Queen Elizabeth was one of the ablest of the series; but historians do not inform us that she wore a beard, though she was spirited enough to beard many a brave fellow in her time. Then, again, Alexander the Great had a smooth face; so had the mighty Cæsar. Napoleon was nearly bald, and quite beardless; and Wellington was a shaved hero. Marlborough wore a wig. Cromwell had a big wart on his chin, and would, no doubt, have concealed it with a beard, could he have grown one; and all the Roundheads were croppies. In that era of stupendous effort, the first French Revolution, the men who concentrated in themselves the spirit of their time were beardless,—Mirabeau, Danton, Robespierre, and the rest. Then, what shall we say about the prophets, philosophers, and poets,—Socrates, and Aristotle, and Locke, and Milton, and Byron, and Burns, and Scott, and Humboldt?—But stay: the first of all philosophers, Newton—the first of all poets, Shakspeare, and the first of all prophets, Elijah, were beardless, and the last two bald. Samson, indeed, was a hairy man; but it is not said that Delilah shaved him—so that it is pretty certain his strength was not in his beard. The immortal Sayers is beardless, and so also his adversary Heenan. All pugilists, ancient and modern, have had a dislike of hair; for, beyond most men, they have a great reluctance to be caught by the beard. Dr Holland wrote a book, some time ago, about cuticular appendages; and a very weak book it was—but that may be excused, for the Doctor wears a beard. Still there may be something to say in favour of beards.

It has been averred that the beard defends a man from catarrhs, sore-throats, and rheumatisms. This is quite true, and as philosophers are much given to mental mumps and metaphysical quinsies, there is every reason why they should be adequately protected from such attacks. General Pennefather, however, seems to think there may be too much of a good thing, and, without abolishing the good, he desires to abate the evil. This seems to us a sensible course, and we hope the philosophers will be of the same opinion.

GRIEVANCES OF THE POOR-LAW MEDICAL OFFICERS.

Mr Griffin is again in the field, with another Draft Bill for the redress of Poor-law Grievances. Unfortunately, Mr Pigott is not now in Parliament, having resigned his seat to occupy the post of Lieutenant-Governor of the Isle of Man, and there may be some difficulty in finding another member so well qualified as he to undertake the conduct of the measure in Parliament. Mr Griffin, however, is sanguine, and has recommenced the campaign, in the hope of finding a leader when the day of action shall arrive. The pamphlet that he has now circulated contains various tables, one of which contrasts the payments per case paid in several instances to the respective Medical Officers of the same Union. We find that one fortunate gentleman is remunerated at the rate of 2*l.* 10s. 10d. per case, whilst another, not so fortunate, is paid 3d. There are other tables, showing the statistics of illness in the several divisions, the number of patients attended by each Medical Officer, and the amounts expended in Medical Relief in each division, with the ratios per cent. to the total Relief to the Poor and to Population. There is also a list of the Unions in which the Guardians either wholly or in part provide the drugs. We observe a remarkable difference in the cost of drugs at the several Unions. In one of the Metropolitan Unions, the Whitechapel, for example, the cost of drugs amounts to 2¼d. only; whilst in another, the Islington (Infant Poorhouse), it amounts to 15s. 7½d.!!

How is this astonishing difference to be accounted for? Some explanation should be given. We do not presume that the Whitechapel Surgeons are homœopaths; on the other hand, any private practitioner whose drugs cost him 15s. 7d. per case would soon find himself in the 'Gazette.' The average number of patients in the Islington Poorhouse is 234; and—will our readers believe it?—the average annual cost of drugs is 183*l.* These are the extremes of the table, but throughout there are wide discrepancies. Some Surgeons must be exceedingly fond of new and expensive drugs, and give plenty of them. We refer to these figures for the purpose of soliciting further information, and because, if they be correct, the caprices they exhibit in the mode of ordering physic will effectually deter Boards of Guardians from adopting the system of supplying the drugs. We shall revert to these points on another occasion.

FEMALE INDUSTRY.

The ladies have set seriously to work to organise some mode in which their services might be made useful. Miss Bessie Parkes leads the van of this movement, and is doing herself much honour by the talent and perseverance she displays. As Medical Practitioners, we must feel a lively interest in this laudable endeavour; for, independently of the advantage that would accrue to our own Profession and to our patients if one of the objects these ladies have in view—that of an institution of a large body of educated and trained nurses—

were carried out, we must also sympathise with every effort to devise means which, by exercising in a more varied and active manner the physical and mental powers of the weaker sex, should diminish the number and severity of those diseases from which they peculiarly suffer. There is one danger, however, in this proposed reform, namely, that by bringing female labour more directly into competition with male labour, the woman may be forced into exertions which the stronger constitution of the man alone could endure. We know already how hard women work as seamstresses, and how great the deterioration of their health from their prolonged sedentary employment. Much of the evil, in these cases, arises from the fact that women compete with men in this description of labour, and that, consequently, only the lowest and worst-paid kind falls to their share. By organization and the creation of a different feeling among the public, woman's work may be made less laborious and more profitable.

THE SPIRIT OF THE PERIODICALS.

(Continued from page 307.)

and sebaceous glands of the skin, as one of the most important of the physiological actions of the bath. The increase of the absorbing function of the skin is probably of considerably less importance. It is certain that oxygen and other gases are absorbed by the skin, and we know that it absorbs water. This leads me to notice again the great difference between the vapour and warm water and the hot dry air bath. In the one case water is absorbed by the skin. We know perfectly well that thirst is thus allayed by immersing the body in either fresh or salt water. In the other case, instead of water from without being absorbed, water from within is poured out in great abundance. Again, evaporation from the skin exercises a regulating influence on the temperature of the body. Suppose one person to be in a vapour bath at 120°, and another in a chamber of dry air at the same temperature. The general circulation is quickened in both. The blood-vessels of the skin in general, and those of the sweat-glands in particular, receive more blood. More perspiratory fluid is secreted in both. But here the resemblance ends. In the dry air the exhalation rapidly passes off by evaporation, and the body is cooled; but in the vapour bath there can be no evaporation, and the regulating influence upon temperature is lost. Thus, *providing perspiration is established*, a person feels much cooler in a dry air bath at 120° than in a water or vapour bath at the same temperature. People are apt to make a mistake here if they judge by their sensations on first going into the bath. The moist air at first appears the more pleasant. Moistening the skin brings on perspiration more quickly. Until perspiration commences, the dry air may be oppressive; but once established, and evaporation commences, the verdict is always in favour of the dry air. Hence the propriety of introducing a little vapour into the tepidarium. I say little about what is termed 'the respiratory function of the skin,' because I have never seen any very definite account of the relative share of the lungs and the skin in the oxygenation of the blood. But it is very clear that by increasing the cutaneous capillary circulation, exposing the whole body to the air, and removing all superfluous layers of epidermis, we must favour most materially the respiratory power of the skin. In cases where the lungs or the bronchial mucous membrane are diseased, and the heat and nutrition of the body are suffering from defective arterialisation of the blood, the skin may thus become a compensating organ for the faulty lungs. Perhaps this, together with the soothing effect of the moist air of the tepidarium upon the air-passages, may explain some of the good effects witnessed in consumptive cases by the use of the bath."

The Author then dilates upon the virtues of the Bath in various forms of disease in which he has seen it employed.

Dr John Conolly continues in the same journal his *Recollections of the Varieties of Insanity*. Mr Sedgwick contributes the following case of *Partial Turning:*

"Mrs A., a short, muscular woman, aged thirty-seven, sent for me on December 2, 1858, to attend her in labour of her tenth child. Her former medical attendant told me that previously her labours had been tedious on account of small pelvis, and that three times cross presentations necessitated turning, but that nothing unusual occurred.

"At two p.m. pains set in, and at seven p.m. I saw and examined her. The os was fully dilated, the membranes entire, and the perineum perfectly dilatable: the hands presented with a shoulder. Having determined that the feet were placed posteriorly in the uterus, I turned the child immediately with my left hand; bringing only one foot to the vulva, I endeavoured by gentle traction (several times repeated) to bring it further, but was unable to do so. The pains continued about an hour without causing any apparent progress, so the patient was allowed to leave her bed. Shortly the pains became much stronger and very urgently complained of, and on examining her when again in bed, I found the head occupying the brim of the pelvis, but prevented entering it by the foot already at the vulva. I at once used constant gentle pressure on the foot and pushed it above the head, when a few strong pains completed the delivery, the occiput being directed anteriorly; in fact, the child was born as in perfectly natural labour.

"The child did not breathe naturally until the warm bath was used, and artificial respiration had been used for about half-an-hour. Marshall Hall's plan was adopted.

"*Remarks.*—Probably some of your readers may have had similar cases, though no medical friend of mine has, and I find no record of such a case. The case was evidently not one of spontaneous evolution as ordinarily interpreted, but very probably one in which the body of the child was doubled on itself by strong uterine contraction. I believe this to have been the case, because the foot could not be brought externally, and because artificial respiration was required for so long a time on account of impeded circulation. On this supposition the breech could not enter the pelvis, on account of the head continuing to occupy a lower position in the uterus, and by such a position it would check the circulation through the placental cord when traction was made at the foot and with uterine action."

We extract from the 'Journal of Practical Medicine and Surgery' the following article on the *Transmission of Syphilis by Vaccination:*

"M. Viennois presented to the Academy, through M. Depaul, a pamphlet entitled, *Transmission of Syphilis by Vaccination.* M. Depaul passed upon this work a well-deserved encomium.

"The transmission of syphilis by vaccination has been observed from the earliest period of the present century, and has doubtless largely contributed to strengthen in some quarters resistance to the preservative from small-pox. The 'Journal of Practical Medicine and Surgery' published in 1831 a communication from M. Bidart of Le Pas-de-Calais, who, endeavouring to exculpate vaccination from the various charges brought against it, related two instances of vaccination of healthy subjects with matter supplied by persons infected with syphilis; in neither case was disease communicated, hence the Author inferred that syphilis could not be propagated in this manner. The Society of Medicine of Paris expressed its concurrence in this opinion in 1839; somewhat later, however, Messrs Pitton, Boucher, Ceccaldi, and Lecoq recorded experiments and facts which placed beyond doubt the possibility of the transmission of syphilis by vaccination. To refer to more recent events, we may mention the great Hubner case, which in Germany has remained memorable among members of both the medical and the legal professions. On the 16th June, 1852, thirteen children from one village were simultaneously vaccinated on the same day, with the vaccine matter supplied by the child Keller alleged to have been affected with syphilis; now in some of the children obstinate ulcers broke out in the punctured spots, and genuine syphilitic eruptions made their appearance three months after, whereas others escaped uninjured. How was the infection of the former or the immunity of the latter to be accounted for? How was it that syphilitic contagion, admitted to be possible in this manner, and actually proved to have taken place in certain instances, still remained an unusual and exceptional circumstance? These questions long awaited an answer, but, thanks to the researches of M. Rollet, Chief Surgeon of the Hospital of L'Antiquaille at Lyons, and the author of a pamphlet published during the present year, entitled 'De la Pluralité des Maladies Vénériennes'—thanks also to the active clinical inquiries, and the careful analysis of the cases on record, instituted by one of his most able pupils, Dr Viennois, these problems, which hitherto seemed to defy the sagacity of the most discriminating observers, appear now to have received at last a satisfactory solution.

"M. Viennois remarks that a careful perusal of the cases of syphilis noticed after vaccination leads to their division into two groups. The subjects on the point of being vaccinated were either already labouring under syphilitic infection, or not. Among the first may be classed all the individuals in whom syphilis was latent; in the other, subjects in the enjoyment of perfect health, free from hereditary or acquired venereal disease, and in whom syphilitic symptoms broke out subsequently to vaccination only. The first group is justified by the fact that any eruptive disease may become the occasion of the manifestation of latent syphilis. The second group seems equally legitimate; but in the numerous cases upon which it is grounded, are we to attribute the circumstance of syphilitic contagion to the vaccine virus? Assuredly not; were it otherwise, the infant Keller mentioned above, who supplied the matter with which thirteen other children were inoculated, would have contaminated the entire number, whereas eight only became infected. This was due to the fact that vaccine matter alone seems incapable of transmitting aught but vaccine, and to be as powerless to communicate syphilis as any other morbid poison. How are we, then, to account for the instances of genuine contagion of syphilis by vaccination which have been placed on record?

"The explanation, says M. Viennois, is extremely easy.

"The lancet meets in the pustule of vaccine with two kinds of fluid:

"1. The vaccine virus;

"2. An adventitious liquid, blood, when the point of the lancet has penetrated beyond the cavity which contains the vaccine matter. Now, despite the denial of Hunter and M. Ricord, the blood of persons labouring under constitutional syphilis undoubtedly possesses contagious properties, as it does in all virulent disorders, such as glanders, rabies, rot, small-pox, diphtheria, the plague, &c. M. Viennois relates five direct experiments performed with the blood of persons affected with secondaries, which confirm the data of analogy. M. Rollet, in his public lectures at L'Antiquaille in 1859, professed and demonstrated that syphilis is not transmitted by vaccine matter, but by its admixture with blood.

"With regard to the symptoms observed in persons to whom syphilis has thus been communicated, they are of two orders, primary and secondary. Invariably the first appearance is chancre of the arm, secondaries breaking out after a time only. When, on the contrary, latent syphilis manifests its presence under the influence of vaccinal fever, no primary ulcer is observable upon the arm: but papular, vesicular or pustular eruptions give evidence of the existence of syphilitic infection.

"The treatment of the disease thus acquired demands no special notice: the important point is to obviate such transmission by appropriate prophylactic precautions. This is undoubtedly possible, and vaccinators and heads of families may, in this respect, rest perfectly satisfied.

"In all the cases of vaccinal syphilis which he relates, M. Viennois has been struck with the fact, that the operation had always been performed from arm to arm, viz. under the most favourable circumstances for the inoculation of blood. In no instance was preserved vaccine used, *i.e.* pure unadulterated vaccine matter. Now, as before stated, pure vaccine virus, even taken from a person labouring under venereal infection, propagates vaccine only: now, therefore, vaccinators are cautioned and will carefully avoid the addition of even the smallest particle of blood to the vaccine virus.

"The foregoing observations apply not only to the liquid matter, but also to the desiccated crusts. When the latter contain but the secretion in its dry state, vaccine only will be communicated; but should it be mixed with dried blood, and the subject from which it originates be tainted with syphilis, that disease may be transmitted.

"As to vaccination from arm to arm, M. Viennois remarks that the most certain method of avoiding the inoculation of the venereal poison lies in

charging the lancet with pure vaccine matter only. Should the operator fancy that any blood has been also abstracted, the instrument should be cleaned, and the vaccine matter sought for elsewhere, or the vaccination postponed. A procedure which seems perfectly safe, consists in collecting the vaccine virus in a tube, and carefully ascertaining its transparency; it may then be blown out, and the lancet charged with the fluid. It is further prudent to ascertain the state of health of the parents, and, in case of doubt, to gather the vaccine matter from the arms of children sufficiently advanced in life, to be safe) from the appearance of congenital secondary disease."

The same journal contains the following article on a generally unnoticed cause of *Protracted Natural Labour*, and a safe and easy means of shortening its duration:

"Obstetricians profess the opinion that, in natural parturition, matters are so disposed as to facilitate its accomplishment, and that protracted labour is referrible but to the insufficiency of the expulsive power, or to the rigidity of the soft parts, which must be distended and dilated to afford a free passage to the child. They opine that the contact between the bones of mother and fœtus can induce but temporary obstruction, and consider it even as sometimes favourable to the egress of the fœtus, and therefore to the rapidity of labour. Dr Bourbousse de Laffore, Chief Physician of the Asylum for the aged blind (Hospice des Quinze-Vingts), does not share in this general optimism, and endeavours to show, in a memoir he has forwarded to the Academy, that in most cases protracted labour, in natural parturition, is referrible to the obstruction caused during uterine contraction, by the occiput or whatever part of the fœtus presents, abutting against the symphysis pubis.

"After a rapid description of the anatomy of the parts to be traversed by the fœtus, and the position of the child and uterus with regard to these, the Author proceeds to say:

"Direct examination of the parts during the pains shows that at each uterine contraction, the head of the fœtus meets the symphysis, a contact which interferes with, when it does not absolutely obstruct, the descent of the vertex into the true pelvis, the uterine force which acts upon the head being neutralized by the resistance of the symphysis. Thus, when, after the rupture of the membranes, the fore-finger is applied upon the cervix uteri during an interval of the pains, the cervix is found to be moveable within the pelvis at some distance from the symphysis; but as soon as contraction recurs, the os uteri is suddenly brought close to the symphysis, and vigorously squeezes the finger, if it be not withdrawn in time, against that bony surface. The extremity of the finger is then caught between two bones, the occiput and the pubis, and cannot be removed while the contraction lasts, a space of time which the amount of pain causes to appear considerable.

"'I have been caught,' says M. de Laffore, 'in this trap, and if I did not scream it was not for want of inclination. Being now cautioned, I easily avoid it.'

"For this purpose it will be found sufficient to apply the fore-finger upon the cervix, and during the contraction of the uterus to press upon the vertex, so as to prevent the head from approaching the symphysis. The finger may moreover be used as a lever, the fulcrum of which would be at the pubic arch, to direct the occiput backward and downward so as to place it in the centre of the true pelvis, and bring it nearer to the perineum.

"The head, powerfully propelled by the expulsive power, and meeting with resistance from the soft parts only, thus descends below the pubic arch, dilates the os uteri completely, promptly reaches the lower parts of the pelvis, which it distends, and issues from the ontlet after a few strong contractions, increased in their energy by the mother's pleasing consciousness that labour, which she imagined could be brought to a conclusion but by the dreaded intervention of instruments, is approaching its close.

"When the pains rapidly follow each other, the finger may be permanently kept upon the cervix, but pressure should be exercised during contraction only; should the intervals between the pains be longer, four or five minutes for instance, the finger should be withdrawn after each contraction and reinserted at the beginning of the next.

"If, from the close approximation of the symphysis and occiput, it is found impossible to apply the pulp of the finger upon the cervix, the palmar aspect of the hand turned towards the sacrum, it may be introduced in an inverted position, *i. e.* with the pulp turned towards the symphysis. The head then bears upon the finger-nail, and at each contraction of the womb gently glides along the inclined plane formed by the latter.

"Both these procedures lead to the same result, viz. *the rapid expulsion* of the fœtus; but when the operator has the option, the first is preferable.

"'It would be impossible for me to enumerate here,' says M. de Laffore, 'the numerous instances of tedious natural labour I have observed since 1843, in which this innocuous method has rendered signal service. Twenty midwives, whom I could name, have summoned me to apply the forceps, in order to bring to a conclusion *natural labour* which had lasted twenty-four, thirty-six, and even forty-eight hours without progress, despite the continuation of uterine contraction, and the proper conformation of both the fœtus and the maternal pelvis. In these cases, instead of applying the forceps, as I was urged to do, I have merely used pressure with the fore-finger upon the presenting part of the fœtus, in a downward and backward direction, and invariably, *in less than an hour, nay sometimes in a few minutes*, I have delivered the patient of a living child, without inducing pain or injuring in the slightest degree any of the organs. I may add, that several practitioners and some midwives to whom I had described my method have informed me that they had resorted to it in tedious labour, and had thus much accelerated its conclusion.'"

GENERAL CORRESPONDENCE.

REMARKS ON TWO CASES OF PARAPLEGIA AND PARALYSIS.

To the Editor of the Medical Circular.

Sir,—It is totally impossible for any person to read the recorded cases in the Medical Journals without seeing that the same remedies are often prescribed for totally opposite diseases, or the general causes of them, and that totally opposite ones are given in the same diseases without any reason assigned for the discrepancy. This is done so continually and universally, that I am surprised the acute Medical minds of the present day, imbued as they are with chemical ideas, do not see something like chemical actions in the body in disease. There are a host of diseases which are admitted by our best authorities to come under the head of *acid diatheses*, and always accompanied by a *furred tongue;* and these, by a further, though only partial admission, are considered congestive states. Now, there are others of an inflammatory type, such as muco-enteritis, *per se*, and a similar condition in scarlet fever, where the tongue is not only denuded of its fur or pile, but is inordinately clean and red. But the Profession has not come to the point of admitting this to be an *alkaline* diathesis; but why not? A certain amount of empiricism declares that alkalis are the antagonistic agents for the congestive or acid states. Combined with the antimonials, deobstruents, diaphoretics, and such like simple yet efficacious remedies, they are clearly the medicines to be used to neutralise and otherwise remove the obstructing elements producing them. On the other hand, the inflammatory states of mucous membranes, as alluded to above, have acids and anodynes empirically administered for their benefit—not to reduce an alkaline action in the same way as acids are reduced by alkalis, but for some purpose empirically understood as beneficial. If no other philosophy for this treatment exists, it may at least be inferred that the system is deficient in these elements,—therefore they are given. Let any one try alkalis, soda, potass, &c., in scarlet fever, with a fiery red tongue present—or in pure muco-enteritis, or in the inflammatory fevers, and he would be safe to kill his patient. Usage, and in fact all empirical dogmas, are against this. As well may acids be given for the congestive actions, to the increase of their elements, already too abundant in the system.

Whatever may or may not be said of the actual administration of medicine, it must be given in one of three forms—acid, alkaline, or neutral,—under which latter term are those medicines which have certain actions on muscles, nerves, &c., and are therefore mechanical, and are excitants without having chemical actions. If furred tongues denote congestive or acid conditions generally, and red and fiery-looking ones their opposite, then the empiricism of the administration of medicine is in many instances correct. In speaking of these matters, I have only to do with the philosophy of the question; with principles, not men.

In your excellent journal of the 24th ult., there are two cases recorded of *Paraplegia and Paralysis*, from Guy's Hospital, under Dr Gull.

The first case, Eliza Coates, was admitted for paralysis on "18th July, 1860." "Complexion ruddy, with an anxious countenance;" . . . "sensations not impaired;" . . . "sphincter muscles not affected." "Has three or four circular spots on her upper extremities of the nature of *herpes*. Bowels constipated, lips parched, TONGUE FURRED." "July 23rd. Bowels relieved." "Aug. 4th. Troubled with bright *muscæ volitantes*." . . . "Bladder distended." "Breathing mostly superior thoracic." "Pulse, 136; respiration, 36." 8th. Died. No autopsy." On admission was ordered "Julepi rosæ, ℥vi.; quinæ disulph., gr. j.: singulis dosibus bis die." "Middle diet." "25th. Pulv. ipecac. co., gr. x.: om. n. Julepi iodinis, ℥j.: ter die." "Aug. 4th. Pergt. pulv., om. n., et julep." "Aug. 7th. Sp. æther. sulph. co., ℥xxii.; aq. camphoræ, ℥j.: 6tis horis. Wine, ℥j."

The second case, Ellen Bushel, was admitted for paraplegia on "9th Aug." last. "Complexion ruddy, TONGUE FURRED, appetite moderate, *pulse hard and rapid*." . . . "No loss of sensation." "Has a slight pain in her left side." . . . "Coughs a good deal at night, expectorating a frothy mucus." "Aug. 14th. Feels better; coughs a good deal." "17th. Coughs more at night." "22nd. Not so well; good deal of pain in chest; perspiration profuse at night; giddiness; feels very weak." "28th. Went out; . . . and did not feel herself improved." On admission she was ordered "infus. cascar., ℥jss.; pulv. rhei salin. (p. rhei et pot. sulph.), gr. xv.: bis die."

As no other medicine is mentioned to have been prescribed, I presume none other was given. The only other remedy was mechanical.

"11th. Sparks of electricity to be taken from her back three times a week."

In the first case, the herpes, furred tongue, *muscæ volitantes*—so frequent in acid states of the stomach,—in fact, all the symptoms proved the congestive or acid condition of the system. The medicines administered were acid and quinine, and Dover's powders. In the second, the furred tongue, hard and rapid pulse, cough with frothy expectoration, pain in the chest from loaded or congested bronchial tubes, giddiness, and all other symptoms, proved also the congestive or acid condition. The medicines administered were infus. cascar., an astringent tonic, and a warm saline aperient.

Here, then, in two very similar conditions of the system, totally opposite remedies were given. The latter was not at all improved, because the very elements which produced disease were more encouraged by the means employed to relieve them; and in the other, the acid and anodynes were given, which tended to increase all the evils present. Surely, Sir, there must be something radically wrong in our *modus medendi*. Everything seems right and correct till we come to that. I could multiply these cases *ad infinitum*, from hospital reports alone. It is constantly occurring in the reports of cases from country practitioners, but it is useless to comment on them. The schools and centres of error must be attacked. What can any one learn from these cases? What philosophy dictates the administration of medicine? What are students to remember when such a jumble of empiricism without system is exhibited to them? Cannot congestive and inflammatory paralysis, congestive and inflammatory apoplexy, congestive and inflammatory phthisis, bronchial congestion and bronchitis, congestive and inflammatory cholera, congestive and inflammatory rheumatism, congestive and inflammatory conditions of mucous and serous membranes, be discriminated? They are as opposite as the Poles! The former are attended invariably with *furred tongues;* the latter, with *clean, red or dry and brown ones*. The former require all the alkalis, stimulating expectorants, and every form of medicine in the Pharma copœia, to neutralise these causes of vital excess and expel the enemy from the camp; the latter, all the acids and anodynes, to arrest the progress of matter or vital powers from flying away too quickly. The thing is simple enough. A clock that is weak from its wheels being overloaded with dust, requires only to be cleaned: such is congestion! The clock whose wheels are wearing will soon be of no use—it is wearing out: such is inflammation! In the cases I have quoted, I have no hesitation in saying, dust was added to the one by the astringent remedies; and to the other which died, elements that were already wearing it out, thereby hastening the end. The administration of medicine is not to be advanced by snuffing up cases and wrapping ourselves up

in complacent satisfaction at our attainments, but by a knowledge of our defects, and admitting and confronting them. The practice of Medicine has to pass this ordeal; and the sooner it begins, the better. No authority should be respected without its accompanying philosophy. No medicine can cure two opposite diseases; and in the ten thousand laboratories of the body, no medicine should be given without regard to its chemical or mechanical laws. We must admit chemistry in medicine, or throw it overboard entirely. We must admit the chemical analysis of all our structures with the metamorphoses constantly taking place in the destruction and renewal of the constituents of the healthy body by chemical changes, or dismiss it from all our calculations. No disease can be cured, however specific it may be, except through the general system and its laboratories, aided by the chemical laws and chemical constituents of medicine and diet. I cite the above cases to show that no such philosophy existed in their treatment, and therefore they were failures.

I am, &c. BENJAMIN RIDGE, M.D.

THE THERMO-ELECTRICAL BATH A VITAL NECESSARY.

To the Editor of the Medical Circular.

SIR,—These hot-air baths were one of the first institutions and marks of social and sanitary civilisation. Before Babel was, they were. We are told that "traces of them are to be seen in the antediluvian structures of Baalbec." ('Free Press.') The ancient Egyptians, Phœnicians, Chaldeans, Persians, Greeks, Romans, Britons, and Hibernians enjoyed them. . . .

In the hot-air bath we breathe caloric, that immense propelling power of all machinery, through steam, which we receive into our lungs and circulate, without which we die, if it be not developed within us, or that we can inhale it from without. In the blood, caloric seems to re-develop "the life of the flesh;" animal electricity, that vital agent of all, works within us—the source of animal heat, of psycho-physical sensation, of all the electro-chemical and self-poisoning functions that are being performed in the laboratories of our animal life. Caloric circulates in the blood, stimulates and warms the animal body, opens the pores, ventilates the whole system, purifies the blood, and flushes off the whole cuticular sewerage of the citadel of life from within outwards. I know of no drug so congenial to nature, nor so universal in its nature and effects. In the outer world, caloric and electricity seem to act and react upon and reproduce each other, and magnetism under peculiar circumstances, and light as their quality under high intensity of action upon matter. The same thermo-electrical influences seem to be developed within us—probably light also, though it be invisible. The inner psycho-physical constitution of man, who is a duplicate in human nature not to be divided, seems to be a magneto-electric and electro-magnetic steam-engine, which develops and circulates caloric, electricity, magnetism, invisible light, and steam, the grand vital, physical, chemical, and mechanical powers of man's machinery.

Those who suffer from the nervous fears of a hot-air bath, and suggest vapour as an improvement, had better consult that unerring book of books, Nature, and she will, doubtless, answer—Cold water to drink, and hot air to breathe, are the most grateful and congenial aliments and luxuries of life you could offer me. From them in my vital laboratory I can reproduce vapour sufficient for my own purposes; don't suffocate me with it. I discharge it from the lungs charged with carbonic poison; but you would force it back upon my lungs, and thereby reverse the order of nature, which is so noxious to life and health. We should not, therefore, force an atmosphere charged with vapour upon the lungs for respiration. Moreover, when several persons are in the same vapour-chamber, their united respirations must contaminate each other, and pestilential poisons be propagated from such foul air. I trust that no President of a College of Physicians, through "ignorance or accident," will ever again be found to recommend a vapour-bath in preference to a pure hot-air bath taken with all prudent precautions, in which there is an ascending current produced by evaporation of respiration and perspiration from each person towards the top of the chamber, to escape through the ventilator: besides, caloric of high heat —160°—kills all animal poisons; disinfects and purifies the air, as well as the person. I perceive that thirty-one medical men in Limerick have lately solicited the Mayor and Town-Council of that city to establish Baths and Washhouses under the statute. That they are better calculated *to whitewash corporations* than to purify the people, I freely confess, though I advocated the same for Sligo in 1856. I now feel convinced that thermo-electrical life-baths are vastly better and more economical in every sense, and that they must overcome all competition, from their superior scientific merits, and the important improvements introduced by Dr Barter of Blarney. In Liverpool, Birmingham, Bristol, Hull, Halifax, and Sunderland, Baths and Washhouses have been a source of large loss. Reviewed scientifically, they merely provide that the skin *look clean* and appear cleanly clad, which is analogous to whitewashing the outsides of houses and leaving the insides in filth; in like manner the interior of our living tenements may be left in a similar state of neglect. In a warm bath, we *imbibe* by the pores more or less of the contaminated water that we would not drink. The Turks, with some scientific reason, regard the warm-water bath with horror and astonishment. The ancient Greeks and Romans used it only when sick as a means of cure. There has been a vast improvement in medical science since their time. For the information of Town-Councils, we shall review this question with the light of political economy. One pound of coals will heat one cubic foot of water one degree, and the same quantity will heat 2,000 cubic feet of air one degree; so that the quantity of fuel required to heat the bath of one person, 98°, may heat the hot-air bath of fifty persons 150°; and the warm-water bath will only operate upon the surface, while the hot-air bath will operate and permeate and purify the whole blood and body. After the water-bath, you are relaxed, robbed of animal electricity; after the hot air, you are refreshed, and your electricity recruited. This Bath of baths seems to be fast repossessing the professional mind. The paper from Dr Erasmus Wilson of London, read before the Social Science Congress of Glasgow lately, is the latest and most important evidence of this fact. The vital interests of the many in this question of public health seem now so generally understood, that it is impossible that they could be sacrificed at the shrine of the empirical few who drive a fearfully fast drug-trade up and down that grand canal of traffic to them, the intestinal tube, and are suffered to do so for sake of the paltry public revenue. When scientific self-knowledge becomes more diffused over the public mind, this false system must be crushed by the pressure of public opinion, and medical science resume sole and supreme power as the medical director of our human nature. The dignity of this great nation—the splendour of this age of rapid progress, of the quick march of intellect, of social science, of sanitary economy, of personal reform—in one word, of civilisation—demand this position for medical science (for the physician is the philosopher of nature), and the revival of the Thermo-electrical Bath, a luxury of life, and a proof that we are worthy to belong to this "patent age of new inventions," which has produced locomotive steam power from caloric to move at a mile a minute—magneto-electric machines, to transmit electricity, to be our running messenger with the rapidity of thought—light and lightning, to combine on electro-chemical materials and strike off our second selves photographically—chloroform, to kill pain, suspend consciousness, submerge man in a sea of oblivion, and overshadow his soul in sleep on the brink of the ocean of eternity, to hang on a thread of silken slumber, but has lately furnished medical science with the ready resuscitating means to lift him into life again. All honour to the late ever-to-be-revered Dr Marshall Hall for this his last legacy of life to mankind and of light to medical science—"the most brilliant book he ever wrote," he said, but did not live to publish.

Yours truly,
Sligo, 1st November. J. TUCKER, M.D.

POOR-LAW MEDICAL REFORM ASSOCIATION.

To the Editor of the Medical Circular.

SIR,—I shall feel obliged by your allowing me space in your Journal to inform the Poor-law Medical Officers that I have this day ordered a Draft of the proposed Bill on Poor-law Medical Relief to be forwarded to each Medical Officer for his opinion. As it is possible among so many and frequent changes that the names of a few gentlemen may have been omitted, I must request those who do not receive a copy by the 8th inst., but desire to have one, to address a note to me to that effect.

I am, &c., RICHARD GRIFFIN.
12 Royal terrace, Weymouth,
1st Nov., 1860.

HOSPITAL REPORTS.

WESTMINSTER HOSPITAL.

CONSTIPATION—COLIC.

The following is a truly interesting case, and although it extends over a long period of treatment, it is in a practical point of view worthy of the greatest attention. It may be considered the type of a series, the individuals of which are found amongst the sedentary, luxurious, overworked, and ill-fed, as well as indolent females of London. The history of the case shows a complete loss of the peristaltic function of the intestine. Probably, at the commencement, neglect in relieving the bowels might have caused accumulation of fæces in the colon; this increasing to that degree which would prostrate the muscular power of the intestine, necessarily would also aggravate mischief. Hence would originate all the untoward circumstances of this very curious case. On functional relief having arrived by free and spontaneous evacuations occurring, the peristaltic function of the intestines was nevertheless slow to be obtained, and when obtained was both irregular and erratic. Instead of the normal peristasis of the intestine, an inverted or anti-peristaltic action was set up. This state of things characterised the middle and latter part of the progress of the disease to convalescence. These circumstances, with the intermittent or recurrent colicky pains, may be attributed to reflex action of the sympathetic nerves. Much obscurity at the onset surrounded the case; whether hernia, intussusception, cæcal ulceration, or other intestinal lesion existed, was doubtful. The due secretion by the kidneys gave encouragement in the midst of this obscurity.

Elizabeth Whicker, single, æt. twenty-seven, dressmaker, admitted into Adelaide Ward, Westminster Hospital, under Dr Basham.

July 23rd.—Suffering under continued vomiting of dark bilious-looking matter, and pain in the abdomen, coming on at stated intervals. Complains of distinct twisting pains when the attack comes on; no hernia. Bowels have not been opened for four days, and then very slightly; is generally very obstinate in that way. Pulse 152, small and sharp. Tongue moist; clean at tip and edges, and furred down centre. Moist and warm; no thirst; countenance is not expressive of any amount of pain. Abdomen tense and tympanitic; no great pain or tenderness on pressure—except in both iliac regions.

History.—Up to 18th of July has always been healthy; but had been kept awake at night, a few nights, by an abscess in the finger.

On the 18th, was seized with a feeling of spasm in the left side; and after taking some brandy and peppermint to afford relief, commenced retching, which has continued up to the present time without intermission. R Ol. ricini, ℥j.; conf rutæ, ℥ss.; decoct. hord. Oss. pro enemat. statim, et repet. hora somni; stupes terebinth. R Sodæ sesquicarb., ammon. do., ää gr. x.; aq., ℥j. ex. acid. citric., gr. xx.: 3tis horis. Has been under treatment out-of-doors, when gums appear to have been affected by medicine given (hydrarg.)

24th.—Pulse 108, fuller; has not been sick since last night about 12 o'clock; pain in abdomen very much relieved; no action of bowels. Repet. enema. Repet. mist. et add. opii, gr. j. per dosis; enema saponis statim, et repet. quaq. 4tis horis.

25th.—Tongue clean and dry, and thirsty; a very slight quantity of fæces escaped with last injection. Sickness continued during afternoon yesterday, but she has not been so to-day or during night. Repet. pil. 6tis horis. R Decoct. hordei, Oss.; ol. croton. tiglii, gtt. j.: fiat enema.

26th.—Repet. enema stat.; et 7 p.m., do. do. Pulse 104. Enema had no effect; sickness has been very troublesome during night, with bilious

matter. A large quantity of flatus was evacuated, by way of mouth, twice yesterday; tympanitic state of abdomen less.

27th.—No action of bowels; bilious vomiting; pulse 100; size of abdomen decreased; feels as if bowels were about to be evacuated every now and then, with pinching pain. There is an eruption all over surface, resembling that of scarlatina; no sore throat, or other symptom to that effect. ℞ Ol. ricini, ℥ss.; ol. terebinth., ℥ss.; dec. hord., Oss.: fiat enema statim, et repet.

July 28th.—Vomiting continues of same character. Omitt. pil. opii. ℞ Hydr. chlorid., gr. iv.; pulv. jalap., gr. x.: statim. Repet. enema. Bowels have not acted; feels the twisting, colicky pain very much this morning. Pulse 104. Tongue moist, and papillæ of dark yellow colour down centre.

30th.—The powder was followed by violent vomiting and retching; matter vomited of same character during yesterday and to-day. Tongue dry and furred; pulse 88. No abdominal tenderness. The eruption has disappeared.

31st.—In much the same state. Bowels not acted. ℞. Ol. ricini, spir. terebinth., āā ℥j.; dec. hordei, Oss.: fiat enema, si opus sit.

August 1st.—Tongue clean and moist; pulse 96; bowels still torpid. She vomits dark, offensive fluid; does not take any nourishment; no anxiety of countenance. Bowels have not acted; still continues vomiting stercoraceous matter; countenance calm and natural; abdomen soft, tympanitic; tongue somewhat inclined to be dry. ℞ Tr. opii, ℥ij.; decoct. hordei, ℥j.: pro enema, hor. som. ℞ Sapon. dur. pro suppositorius.

August 3rd.—Pulse 92. After the last enema of opium, she went to sleep, and had a very comfortable night's rest. Has not been sick since yesterday afternoon; bowels have not acted yet; vomit thin, stercoraceous. One p.m.—Countenance placid, natural; stomach remains quiet; pulse 116. ℞ Tr. opii, ℥ij.; decoct. hordei, ℥j.: ft. enema hora somn. Yesterday afternoon, after examination by finger was made of rectum, a piece of soap was introduced, and retained since. An injection of tr. opii was given in the evening, and another suppository of soap introduced. She slept the whole night, and was this morning free from pain. Both suppositories have been retained. Tongue moist, less fluid; abdomen soft, and yielding and tympanitic.

4th.—Is sitting up this morning; says she feels as if she should choke upon lying down; tongue moist, rather furred; pulse 116; belly more tympanitic; complains of a great load over region of stomach, and fancies she would be relieved if she were sick; has not vomited since 2nd; the suppositories have been retained. The injection was given last night, but she did not sleep; felt sleepy, but could not do so from pain and the sensation of bursting. Countenance quiet. There has been some discharge of flatus downwards. Repet. enema statim, et vespere et bis die.

6th.—Pulse 108; tongue dry; well-raised papillæ; bowels have not acted; countenance rather anxious; complains of constant pain about shoulders; has been sick only once—thin, not stercoraceous; slept during last night and night before; abdomen more tympanitic; discharge of flatus downwards. Fotus calid. abdominis. Repet. enema.

7th.—Pulse 120; tongue dry and brown, streak down centre; countenance drowsy; conjunctiva injected; has been sick only once, and that very slightly, not stercoraceous. There was more discharge of flatus last night than at all; no fæces; abdomen very tense.

8th.—Pulse 120; tongue dry and clean; has not been sick since last note; passes flatus occasionally downwards, and states that a few white lumps escaped from rectum last night whilst trying to empty her bowels; slept pretty well.

9th.—Yesterday had some action of bowels, not in consequence of injections, but spontaneous. She passed a considerable quantity of dark fæces; she has vomited a great deal of stercoraceous matter during night. Pulse 100; tongue moist; abdomen less tympanitic; has been sick once this morning, still stercoraceous; complains of great pain about region of stomach.

10th.—Pulse 120; expression more anxious; did not sleep in the night, from occurrence of periodic attacks of a sort of windy colic; had a motion yesterday, not very large, but about consistence of a poultice; has been violently sick all night; urine plentiful.

11th.—Pulse 120; the want of food is telling upon the countenance, the face looking thin and sharp, and the bowels prominent. No evacuation from bowels to-day; slept a little; vomited a little yesterday, very stercoraceous. ℞ Tr. opii, ℥ij.; decoct. hordei, ℥iv.; sodæ chlorid., ℥iv.: ft. enema statim.

13th.—Yesterday, after an injection of turpentine and oil, the bowels acted freely; several lumps came away, and has had four evacuations since. Countenance tranquil; pulse quick; tongue clean and dry; sickness still continues.

14th.—Bowels acted three times yesterday, a number of hard lumps still being brought away. Pulse 120; tongue dry; has been sick several times during night, vomiting yellow bilious-looking matter, not stercoraceous; complains a great deal of colicky pains.

15th.—Bowels moved once yesterday, not since. Slept all night; no sickness since night of 13th; ate greater part of her chop yesterday with a relish; still feels the windy pain now and then; pulse 112; tongue clean.

16th.—Pulse 120; tongue clean and dry; has not been sick; no motion; pain increased, of same character. Fotus terebinth. abdominis appl. Repet. enema.—1 p.m. Vomited again.

17th.—Bowels acted three times after injection; motions copious, light-coloured. No return of vomiting; feels sick; slept well.

18th.—Bowels acted freely; motions natural, three since yesterday. Colicky pain has been very bad during night; has been sick ever since yesterday. ℞ Sp. ammon. arom., ℥ss. ℞ Lav. co., ℥ij. ℞ Zing., ℔x.; aq., ℥ss.: flatus urgent. sumend.

20th.—Sickness continues; bowels act every morning, especially when the draught has been taken. Colicky pain still felt, not relieved by medicine. Middle diet; one egg.

21st.—Bowels open; sickness still continues. Yellow-looking sour water vomited. Pain still very severe at times.

23rd.—Bowels act naturally; sickness and pain continue. A rhubarb poultice ordered to be applied to stomach. (a)

24th.—Bowels open. Sickness is more violent; vomited yeasty-looking fluid. Pain very bad. Poultice had no effect. The pain has been spasmodic all along, and the course of the large intestine can be felt raised and hard during each paroxysm. Repet. enema opii et sodæ chlorid.

25th.—Bowels open. Pain relieved by injection; has not returned since.

Although sickness continued after taking food on 26th, 27th, 28th, and 29th, the bowels nevertheless acted regularly every morning, and pain became relieved. Matter vomited to-day, green, bilious-looking, mixed with food.

Forwards to Sept. 5th.—Vomiting continued occasionally after almost everything she took. But for this state of things, she might be considered convalescent. To-day the sickness has been absent for the first time; she has not vomited after taking egg and wine, and has kept bread and milk upon her stomach. From this time the appetite returned and became good, pain left her, the bowels became open every day, and she slept well.

From the 7th.—She took all her diet, but only a mouthful or two at a time, which was repeated every hour or two during the troublesome continuance of the sickness, to give the stomach as little to do at a time as possible. From this time until her discharge, she rapidly improved. Dr Basham deferred her discharge to October 16th. To restore her strength and condition, she continued in the house, taking everything that could conduce to that effect; namely, wine, beer, and *extras*. Before leaving, she regained not only her strength, but her flesh began to feed. The pulse continued quick to within a few weeks of that period. The tongue became moist and clean, and bowels open daily.

We are indebted to Mr Mowatt, Physician's Assistant, for his careful notes of this interesting case.

(a) Dr Basham, by way of experiment, applied this poultice. The irritability of the stomach rejecting everything attempted to be introduced that way, and barbarine being considered to exert an especial influence upon the fibrous coats of the intestines, he thought it a fair opportunity of trying its agency by its absorption through the skin. The barbarine Dr Basham afterwards traced to have become absorbed into the system, but its influence was *nil*.

UNIVERSITY COLLEGE HOSPITAL.

OCTOBER 20TH.

The boy Henry Pinchett, whose case we gave partially last week, we saw to-day. He is progressing so favourably to cure, that a few days will probably terminate the treatment of this interesting case, when we will give Mr Holland's notes of the termination.

MEDICAL SOCIETIES.

MEDICAL SOCIETY OF LONDON.

MONDAY, OCTOBER 22ND, 1860.

PETER MARSHALL ESQ., VICE-PRESIDENT IN THE CHAIR.

CLINICAL DISCUSSION.—MALFORMATION.

Mr CANTON exhibited a drawing of a case of malformation which fell under his care in the Charing Cross Hospital. The patient was a male child, six months old, was born at the full term and presented the peculiarity of having a fleshy caudal appendage prolonged from the posterior margin of the anus, upwards and forwards, to become continuous with and project greatly from the surface of the raphe of the perinæum. It terminated by becoming identified or lost in the raphe of the scrotum. The whole of the growth was conical, with its base attached, and, as it were, springing from the posterior margin of the anus, just opposite to the coccyx. It did not completely occlude the anal opening, and there was a tolerably free vent for the fæces or either side of it. Since birth, the contents of the bowels were said to have been almost continually flowing. The mother has other children, who are well formed, and she is not aware of any injury or fright occurring during her pregnancy. Mr Canton removed the whole of the growth, and ascertained that the sphincter ani was not ill developed, and the coccyx was not prolonged to its normal extent.

The Vice-President, Dr Salter, Dr Halford, and other Fellows, joined in this discussion.

OPIUM-EATING.

Dr STOCKER then called the attention of the Meeting to the constant use and abuse of opium. He was lately called to attend upon a lady who had a tumour under left mamma. A plaster of opium had been applied. He traced out where this was obtained. An ounce a day had been taken for six or seven years, or ten grains a night. Opium could be obtained on all occasions by merely asking for it. Dr Stocker said, upon remonstrating with the seller, he replied that he made no profit by it, as an excuse for its sale.

Dr CAMPS mentioned the case of a lady who had consulted him, the lady of a Member of Parliament, addicted to laudanum-taking. It was her custom to take ℥xx every eight days, or an imperial pint. She broke herself of the habit, and became restored to health. Dr Stocker thought the subject demanded the interference of Government; the evil had rapidly increased, and had become a dangerous propensity.

THE USE OF MERCURY IN DISEASE OF LIVER.

Dr THUDICHUM would call the attention of the Fellows to the question whether mercury had any action on the liver, or not. He begged to call their attention to the able paper which Dr Inman of Liverpool had recently communicated upon the subject in the 'Lancet.' He stated, he had great faith and confidence in his statements and facts. He was quite prepared to amplify and corroborate them. A writer in the 'Lancet' says he found mercury in the bile. But neither mercury nor calomel is dissolved in it. We understood him to say that it diminished the quantity of bile: Dr Scott has established this point. In reply to Dr Routh and others, Dr Thudichum said, because it produces relief in liver disease, that fact does not prove it to possess a specific action as a chologogue: or the circumstance that the stools are mostly green is no criterion of its chologogue agency. This notion appears to be at the bottom of the tissue of errors. The green colour of the stools produced finds a parallel in the black stools produced by taking into the system the sesquioxide of iron. As this change of colours takes place, so is the cholochrome of the bile generated in the intestines. When after a dose of calomel green stools occur, scalding is produced; this is from the formation of sulphide of mercury. The amount of solid bile fluctuated between 9,000 and 12,000 grains. The dry residue of a healthy man's fæces does not exceed two ounces. Dr Thudichum stated that his own fæces

did not exceed one ounce. The ordinary biliary salts consist of chloric acid. The bile is no criterion at all; it depends upon the quantity of solid matter. The quantity of bile secreted in the ox is extraordinarily large. According to Liebig, the quantity secreted in the human subject is 10,000 or 13,000 in twenty-four hours.

The discussion was carried on by Dr Richardson and Dr Thudichum.

Dr Richardson in answer to an inquiry, what became of the bile? replied, it was taken up by the organic changes going on in the animal system.

Dr Halford referred to the case of a gentleman to whom he was summoned early in the morning. His motions were so hot, they passed from him like boiling water. He had been subject to these attacks. He scrupulously avoided mercury. His bowels were sometimes constipated, and then he had attacks similar to the above, namely—large evacuations of hot fluid.

Dr Camps considered the *modus agendi* of mercury in the system is to favour the secretion of bile. This is no new idea, but rather an old one. If Dr Thudichum be right, we must forget our experiences and our old-day notions for entirely new ones. This doctrine will prove we have for nearly a century used mercury in a very empirical manner. It, moreover, will tend to scepticism in the use of all remedies. Is there any marked line between this state of things and other palpable medical heresies—*homœpathy* for example? In Dr Camps' practice, he said he found blue-pill and two or three grains of calomel so familiarly and confidently resorted to, followed by a black draught, that it has become a household want. It will be a boon to have this rectified.

Dr Salter considered the sub-sulphide abounding might be explained by the quantity of sulphur in the food.

RESECTION OF THE ELBOW-JOINT.

Mr De Meric called the attention of the Meeting to a case of resection of elbow-joint, which he had performed in the usual way, two months ago. This patient, who was in attendance, had been suffering for two years. His arm was, before operation, useless, diseased, and caused suffering. This seemed, in the opinion of the Fellows, a very creditable and successful case, although criticised by Mr De Meric. There was little or no deformity, only from ravages of disease upon soft parts, showing its violence. It was nearly as long as the sound arm; motion of forearm good; pronation and supination correct; perfect use of hand, and perfect motion of shoulder. Mr De Meric criticised this good surgery of his own (which all seemed disposed to commend), inasmuch as the elbow had not as good motion as before. This was somewhat or partially explained by the mode of operation. A certain code is becoming established for these operations, more especially for the elbow-joint. Is this code essential to success? Mr De Meric stated, that he found the head of radius so sound, that he did not remove any portion of it. By this, a sacrifice of the diseased white, fibrinous junction was made, to obtain an arm of natural length; but, from anchylosis taking place, in consequence it became deprived of flexion and extension. Nevertheless, this was a useful limb: good hand, perfect movement at shoulder, and complete power of pronation and supination, were great benefits; the man, from having been nearly dead, restored—a strong, hale man, in good health.

Dr Halford thought it should have been placed early in a bent position.

Mr Canton admired Mr De Meric's modesty in bringing this case before the Meeting as not successful, and in disparagement of resection. He considered resection to be most favourable in its results. He considered this patient as good a case as he had ever seen. He has great latitude of motion, and, he thought, a good position of limb. They always do better in straight line. Fibrous tissue will always be thrown out better than when bones are placed at right angles. It is a question whether the advantage of being placed at right angles, is not compensated by the great latitude of motion obtained at shoulder-joint. Mr Canton referred to some experiments made by the Sydenham Society upon animals. When cartilage is removed, fibrous structure is substituted and deposited; where cartilage is not reproduced, you have what is called porcelaneous material instead. He thought this patient would yet obtain a larger latitude of motion.

In reply, Mr De Meric stated that he removed coronoid of ulna, but not head of radius.

Mr Bryant said, the operation is the more beneficial and successful, the larger amount of bone remaining. If in this case the head of radius had not been left, Mr De Meric's objections would not have existence. He was surprised at it being considered a failure, or quoted as unsuccessful: it was a first-rate hand and arm, with great latitude of motion, and would be very useful to him in whatever condition the elbow may be. When a sufficient quantity of bone is removed, the straight position being at first observed after operation, at the end of week a little flexion should be used and obtained.

OUR NOTE BOOK.

CLINICAL REMARKS ON TUMOURS WITHIN THE CRANIUM.

Dr Brown-Séquard made some remarks *apropos* of a case he had then under his care, on the general symptoms and the affections produced by tumours within the cranium. The symptoms accompanying such tumours were not due merely to their local effects, but often to increased general pressure. The cranium being a closed cavity, a tumour would produce pressure, and thus produce symptoms differing from those which would result from the local alterations of structure which the tumour occasioned. In such cases, persons were dull, as if coming out of a deep sleep; but were, when roused, often as intelligent as usual, but were slow in replying to questions, and their movements were slow and hesitating.

Again, a tumour might produce effects through parts of the nervous system at a distance from itself, just as irritation of the urinary organs produces paraplegia, or as worms produce epilepsy. The symptoms of tumour of the brain were very various, and could often be by no means explained by its local effect. For instance, a patient might have a tumour in the anterior part of one cerebral hemisphere, and during life present no symptom whatever, so that during life no disease of the brain could be suspected. The patient dying of some disease quite unconnected with the tumour in the head—for instance, pneumonia—the tumour would be discovered at the autopsy. It would, however, often happen that even a very small tumour would give rise to very serious symptoms, and in different cases of quite a different character: thus, it might produce insanity solely in one, hemiplegia in another, epilepsy in a third, and trembling palsy in a fourth. In these cases it would be impossible to admit that the local injury was the cause of the symptoms, as much more extensive disease in the same part might exist without any symptoms; and again, their extreme variety would also negative the view that they could all be due to increased general pressure. Dr Brown-Séquard believed that the phenomena in these cases were reflex. If it were asked why the symptoms were various, he would point to phenomena which were clearly reflex, and still various, from the same cause. Thus, worms in the duodenum would produce in one paralysis of the elevator muscle of the upper eyelid only; in another, epilepsy; and in a third, loss of vision, hearing, smell, or taste,—or, in fact, any form of nervous affection.—'Medical Times and Gazette.'

TREATMENT OF EPILEPSY.

BELLADONNA—QUININE—THE LIGATURE—THE ACTUAL CAUTERY.

Dr Brown-Séquard generally commences the treatment of epilepsy by belladonna. The usual dose of this remedy for an adult is one quarter of a grain twice a day in pill or mixture. It is very rarely indeed seen to produce any of its specific effects, as dilatation of the pupil, in cases of epilepsy. At our last visit one patient came who complained of dimness of vision, and whose pupils were evidently dilated by the drug; but this was the exception, proving the rule, as the case was not one of epilepsy or any convulsive disorder.

In the cases in which there appear to be a tendency in the fits to appear at regular intervals, for instance, once a fortnight, Dr Brown-Séquard prescribes quinine in large doses, *e.g.*, five, ten, and even fifteen grains, to be given at intervals, shortly before the fit is expected. By this means the fit is frequently prevented, and the patient goes on to the next, or even to a longer period. In reference to these large doses of quinine, it is well known that some temporary deafness will often follow; and, curiously enough, Dr Brown-Séquard states that there is a kind of deafness which the administration of this remedy in large doses will cure.

Another therapeutical means in epilepsy is the ligature, in cases in which the aura epileptica, arising from one of the limbs, is present. Dr Brown-Séquard has two patients, both girls, about the age of nine years, in the Hospital, in whom the fits are frequently stopped in this way. The ligature is kept constantly on the arm; when the child feels the warning, the nurse of the ward tightens the bandage, and the fit is prevented. The success in these cases has been very great, and we shall, shortly, by the courtesy of Mr Smith, the House-Surgeon, be enabled to place their details before our readers. It is of great consequence to have the ligature in readiness, so that it may be tightened at once. Grasping the limb tightly will do in the absence of proper means, but it is much better to keep a bandage or folded handkerchief tied on the arm ready to be tightened. Dr Brown-Séquard has invented an apparatus to encircle the arm, and to tighten by a screw, in order that the pressure may be quickly applied.

Dr Brown-Séquard frequently uses the actual cautery locally in a variety of nervous affections. In epilepsy, patients frequently complain of either a pain or a sensation proceeding from some part of the body. A woman, aged twenty, had had fits for thirteen years; they invariably commenced with pain in the left side, just below the mamma. Dr Brown-Séquard applied the cautery to this part in two or three places. The relief was most marked. It had not prevented the fits altogether, but it had reduced their number very considerably. Instead of having them every other day, she had them only once a week. The cauterising iron is heated to a white heat, and is then applied suddenly to the part once or twice. It appears to cause but trifling pain, and the patients do not seem at all to dread its repetition.—'Medical Times and Gazette.'

ON THE CONVERSION OF CYSTICERCUS CELLULOSÆ INTO TÆNIA SOLIUM.

Some time since Dr Küchenmeister having fed a deliquent with measly pork three days prior to his death, found several young tænias attached to the intestinal canal, and Leuckart has since related a case of death from the same cause. But, as there are still incredulous persons, the Author resolved to institute other experiments on the person of a criminal condemned to death. The pork containing the cysticerci was administered on November 24, 1859, and January 18, 1860; and the post-mortem was made on March 31. Almost 50 per cent. of the cysticerci were found in the condition of tapeworms. His general conclusions are—1. The numbers of the tænia which were found must convince the most incredulous of the reality of the conversion. 2. That the tænia really resulted from the cysticerci administered, is seen from so so many being still in an immature state. 3. The presence of so many examples delayed the development. In ordinary cases a quarter of a year would suffice for maturity to be attained. 4. Even under the most favourable circumstances, when the cysticerci are freed of their envelopes, one-half undergo no conversion, and swallowed unseparated the proportion would be still less. 5. Raw, measly pork may be exposed to considerable cold without the cysticerci losing their vitality. 6. In weather which is not hot enough to induce early putrefaction, the susceptibility of development can be retained for at least eight days, and probably for a longer period after the death of the pig. 7. The greater the number of the raw cysticerci that are consumed, the greater number of tæniæ will be found. In one case in which such food was largely consumed, thirty-three portions of heads were found. 8. In persons leading a quiet life, avoiding all excess in eating and drinking, and partaking of a uniform diet, even many of these worms may not give rise to any disturbances in the system. This prisoner, between the time of eating the cysticerci and his execution, was remarkably well in health, a considerable increase in the deposit of fat taking place. 9. Notwithstanding the quantity of separated proglottides at the lower portion of the intestinal canal, the muscles contained no cysticerci. This man,

however, had no vomiting, and none of the embryos of the taniæ entered the stomach, which, according to the Author's investigations, is a necessary preliminary to the appearance of cysticercus in man. 10. The worms were found very firmly adherent in part to the free surface of the intestine, or at the sides of the valvulæ conniventes, and in part buried between these last. They could only be detached with great difficulty, and when the heads were loosened from one portion of the intestine, they at once fastened on to another with just as much force. 11. This explains why a means which, in some cases, acts very efficaciously in expelling the worms, in other cases proves of less avail. Thus, when the head is attached to the free surface of the intestine, or of the valvulæ, sharp purgatives will detach it; but, when placed at the base of the valvulæ, the effect of the purgatives may be only to bury it still deeper, and when the body is expelled without the head, the worm may be reproduced. When the head of the worm has become detached from the intestine, we must not allow it time to re-attach itself; and those medicinal agents alone which induce powerful peristaltic action, and are accompanied by abundant secretion, are to be relied upon for procuring a radical cure. 12. Finally, the Author replies to the reproaches which have been directed against him for his experimental feeding of condemned criminals. He maintains that, as a curable disease only had been produced, the man, even in the event of his having been pardoned, would have sustained no permanent mischief. He declares that, by employing active purgation by means of pomegranate extract, prepared as directed in his work on 'Parasites,' he has never failed in expelling the worm. A further excuse for the experiment is derived from the fact that, owing to the regularity of diet observed by the criminal, and the absence of all excesses likely to give rise to vomiting, there was no possibility of the proglottides obtaining an entrance into the stomach, and becoming thence diffused amidst other of the structures.—'Deutsche Klinik,' No. 20, and 'Medical Times and Gazette.'

A SEVERE BURN TREATED WITH ALUM.

In the July number of the 'Maryland and Virginia Medical Journal,' Dr Wm. M. Turner reports a case of severe burn, that was unexpectedly cured by a new method of treatment. The burn was in a person of broken-down constitution and of intemperate habits, and was very large in extent. The Doctor saw the case first a week after the accident; he says, "A more foul and offensive wound I never saw before in the wards of any hospital. The odour was almost unbearable. The man was quivering with pain, wore an anxious look, and had a small, thready, irritable pulse."

Treatment was instituted, and continued for a considerable time, with no favourable influence. The patient continued, apparently, to sink under the exhausting influence of the offensive discharges, and occasional profuse hæmorrhages. For the purpose of arresting the hæmorrhage, powdered alum was applied, and the general influence was so good as to induce its further continuance. He says, "I continued with the alum powder, dusting the entire surface, and instead of covering with rags spread with simple cerate, I applied the cerate of the impure carbonate of zinc, or calamine cerate. This I did not spread on a cloth, but melted in a large iron spoon, and after the alum was well applied, I poured the melted cerate over the entire surface, and covered the wound with very light oil silk. From that moment I had no more trouble; the man slept so well that anodynes were dispensed with, and nature afforded rest, unaided. The tonic treatment soon produced an appetite, and rich food gave the patient good blood. The wounds healed very rapidly after commencing the alum treatment; and what is more singular, more fortunate, and very inexplicable, there was no drawing cicatrix left. The man is to-day in better health than he ever was, and can walk anywhere he pleases."—'American Medical Monthly.'

A NEW OPERATION FOR AMPUTATION OF THE FOOT.

In the same number of the above-mentioned Journal, Dr A. P. Smith recommends a new operation for amputation of the foot. Instead of disarticulating, as is usual in all the various plans hitherto practised, Dr Smith advises a direct section of the bones. This operation is easier to perform than one that requires the knife to follow the irregular tarso-metatarsal articulations, exposes much less bone surface, and gives a granulating surface of bone rather than a cartilaginous, which is an acknowledged advantage. It is further claimed that "the granulating ends of the bones more readily form union with the surrounding soft parts," and "the preservation of the articulations renders the result more satisfactory, and less limping and discomfort in walking."—'American Medical Monthly.'

Births, Marriages, and Deaths.

BIRTHS.

BROWN.—October 24, at Rochester, the wife of John D. Brown, M.D., of a daughter.

COOTE.—October 23, the wife of Holmes Coote, Esq., F.R.C.S., of New Bridge street, of a son.

GILLARD.—October 21, at Hovingham, York, the wife of Richard Gillard, Esq., M.R.C.S., of a son.

HORNER.—October 21, at Spenser road. Hornsey New Town, Stoke Newington, the wife of Thomas Horner, Esq., L.R.C.P.E., of a son.

KNAGGS.—September 2, at Fort Peddie, South Africa, the wife of Henry Knaggs, Esq., M.B., Assistant-Surgeon Cape Mounted Riflemen, of a daughter.

LITHGOW.—October 11, at Royal terrace, Weymouth, the wife of James Lithgow, M.D., of a daughter.

OLDHAM.—October 18, at West Hartlepool, the wife of Riton Oldham, Esq., F.R.C.S., of a daughter.

TERRY.—October 26, at Mells, near Froome, Somerset, the wife of George Terry, Esq., M.R.C.S., of a son.

MARRIAGES.

CRAWFORD—STODDART.—October 25, at All Saints Church, St John's Wood, W. Crawford, Esq., M.B., Surgeon, R.N., to Marian Catherine, only surviving daughter of the late Rev. John Stoddart, D.D.

MATTHEW—YOUNG.—October 27, at Flitcham, Norfolk, Thomas P. Matthew, Esq., Army Staff-Surgeon Major, to Emilie Frances, fifth daughter of Dr Young, late of Clapham common, Surrey.

SUTTON—WHITMARSH.—October 17, at St Leonard's, Shoreditch, John Sutton, eldest son of John Sutton, Esq., M.R.C.S.E., Finsbury, to Rebecca, fourth surviving daughter of J. Whitmarsh, Esq., Whitmarsh Lodge, Honiton.

DEATHS.

CAMPBELL.—August 25, at M'Carthy Island, River Gambia, Africa, of yellow fever, Charles Drelincourt Campbell, M.D. Univ. Glasg., L.R.C.S. Irel., L.S.A. Dub., Staff Assistant-Surgeon, Army.

GIBSON.—October 26, at Inellan, Scotland, David Gibson, of Glasgow, M.D. Univ. Edin., L.F.P. & S. Glasg.

GILMOUR.—October 27, drowned at the entrance to the Trafford Dock, Liverpool, James Gilmour, of Upper Parliament street, Liverpool, Extra-Lic. R.C.P. Lond., L.F.P. & S. Glasg., L.S.A. Lond.

JONES.—October 19, at Pembroke, Thomas C. Jones, Deputy-Inspector of Hospitals and Fleets, on the Retired List (seniority, July 25, 1855), for many years Surgeon at H.M. Dockyard, Pembroke, aged 80.

MARCHANT.—October 25, at Hampton Wick, Georgina Annie, only child of the late Staff-Surgeon W. D. Marchant, aged 6¼ years.

MUSCROFT.—October 17, at Pontefract, Yorkshire, suddenly, Charles Muscroft, M.D. St Andrews, M.R.C.S. Eng., L.S.A. Lond., aged 35.

NORMAN.—October 24, at High street, Colchester, Essex, John Serjeant Norman, formerly of West Mersea, Essex, M.R.C.S. Eng., L.S.A. Lond., aged 68.

SCOTT.—October 11, at Malta, Martha, wife of James E. Scott, M.D., Surgeon, Rifle Brigade.

SCOTT.—October 11, at Malta, James E. Montgomery, the infant son of J. E. Scott, M.D., Surgeon, Rifle Brigade.

TURNER.—October 20, at Tunbridge Wells, Richard Turner, M.R.C.S. Eng., L.S.A. Lond., aged 44.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 26th ult.:—Robert Foreman Cook, Gateshead; George Joseph Dinham, Mile end; Joseph Frederick Eyeley, Llanymynech, North Wales; Edward Charles Hammond, Cambridge; Hauteville Hone John Sterling, Deal, Kent. At the same meeting of the Court, Mr Walter Frederick Cope Bartlett, late of the Royal Naval Hospital, Hong Kong, passed his examination as Naval Surgeon. This gentleman had previously been admitted a member of the College, his diploma bearing date August 8th, 1856.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the science and practice of Medicine, and received certificates to practise, on Thursday, October 25:—William Batho, Amesbury, Wilts; Christopher Thomas Coward, Stepney green, Stepney; Frederick George Dalton, Westerham, Kent; George Griffith Phillips, Newcastle Emlyn, Cardiganshire; Eliezer Williams, Llandilo, Carmarthenshire. The following gentlemen also on the same day passed their first examination:—William Cribb, Chambers terrace, Camden town; Edwin Rawson, Wilsden, near Bingley.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—Edwin Swinfen Bellyse, M.D., L.R.C.S., and L.A.C., Nantwich, was elected a Fellow of this College on the 17th ult.

ROYAL COLLEGE OF PHYSICIANS.—It has been remitted to the Council of the College to arrange the scheme for carrying into effect the new powers conferred upon the Fellows by the recent Act of electing a president.

LONDON HOSPITAL.—Mr Critchett has resigned his share of the Chair of Surgery at this hospital. He will, however, continue to give his annual course of lectures on Ophthalmic Surgery.

MEDICAL STATISTICS OF PRUSSIA.—The 'Elberfeld Gazette' states that in Prussia, in a population of 17,739,913 souls, there are 358 district physicians; 4,327 having their grades; 996 surgeons, first class, and 643 second class; 1,026 veterinary surgeons; 1,529 apothecaries; and 11,411 midwives.

ON the 3rd ult., Dr Henry Bedwell was admitted a Licentiate of the Royal College of Physicians, Edinburgh; and on the 10th ult., was elected a Fellow of the Royal College of Surgeons, England. Date of diploma as Member, June 1840.

DEAF-MUTISM.—ADMINISTRATION OF CHLOROFORM.—At the last sitting of the Academy of Sciences of Paris, Dr Baudelocque presented a patient of his to the members—a soldier, named Charles Freschalle, who having been seized with typhus fever in the Crimea, lost the power of speech in consequence. On the 1st of September last, having been dumb for four years, he placed himself under the guidance of Dr Baudelocque, who succeeded in gradually curing him. Dr Baudelocque also produced a young boy, born deaf and dumb, and who now can speak and also hear a little. Dr Jeancourt sent in a paper on the employment of chloroform. He considers that whenever the act of breathing is continued regularly during inhalation, chloroformation presents no danger; but when this continuity is interrupted, either by the fault of the operator or the patient, there may be danger. Hence he establishes the general maxim: that, to avoid all accidents in producing anæsthesia, great care must be taken to cause an incessant renewal of the air in the lungs until the sleep has begun. Afterwards it will continue without intermission.

DEATH OF A CENTENARIAN.—On Sunday week, Mr D. Muirhead, of Tynecastle, near Edinburgh, died at the very advanced age of 106 years.

VIOLENT DEATH OF DR GILMOUR, OF LIVERPOOL.—The body of Dr Gilmour, residing at 19 Upper Parliament street, was, on Saturday week, found floating in the Trafford dock, at the south end of the town. The face bore marks of ill-treatment, being much cut and bruised; otherwise the body was generally unscathed, and appeared to have been but a short time in the water.

OUR TROOPS IN CHINA.—The 'Times'' special correspondent says: "Notwithstanding the position of the town, and the many inducements to cholera and typhus, the health of the army is

most extraordinary—very much better than at Tah-lien-hwan. There the per-centage was a little above four, here it is positively only one and a quarter per cent. on the whole force, for 'no one now has leisure to be sick, in such a jostling time.' The excitement carries the men through, for they know they are soon to meet the enemy, and should they fall ill they will be sent to the fleet. However, this state of things could not possibly last amid the close streets and the pestilential atmosphere, redolent of cholera and typhus, which surrounds us, and it is a subject of universal congratulation that we go into the open the day after to-morrow. I am sorry to learn, however, that the force left at Hongkong is in a very bad state, and that the men are dying fast. It is high time that something should be done about this charnel-house for English troops, and I have reason to know that the strongest representations have been made to the Home Government against any European regiment being again stationed there. Kowloon, our new acquisition, affords an excellent site for barracks."

Consumption of Tobacco in France.—The consumption of tobacco in France increases in an immense proportion. In 1815 it was only 53,000,000 lb., and in 1858, 173,000,000 lb., having in that time more than tripled. In a period of 47 years, it produced to the Treasury a gross sum of 4,386,794,264 fr., and a net amount of 3,044,078,346 fr. The sale of tobacco, as is known, is a Government monopoly, and the gross receipts of it are set down in the budget of the present year at 183,000,000 fr. From that sum, however, must be deducted 15,424,000 fr. for salaries; 12,437,200 fr. for rent, buildings, wages to workmen, repairs, supplies of paper, envelopes, salt, and casks; 211,000 fr. for indemnities to departments in which the plant is cultivated; 205,000 fr. for fees to experts; 43,009,000 fr. for purchase of foreign and native tobacco; and 96,933 fr. for extraordinary services; total, 57,501,533 fr.: thus leaving a balance of 125,498,467 fr. to the Treasury. The increase in the price of tobacco just imposed will raise the receipts, it is estimated, to about 220,000,000 fr.

Unwholesome Meat. — All the slaughter-houses in the City were visited during last week, and the Medical Officer reported that the Inspector of Meat, Mr Newman, had seized 1,192 lbs., or rather more than half a ton, of meat that was unfit for human food, all of which had been destroyed.

Epilepsy a Consequence of Tobacco-smoking.—"I may be permitted to state that one of the most severe cases of epilepsy I ever saw arose in a boy twelve years of age, who had been for some time a tobacco-smoker, which habit he continued after the disease attacked him, and it was in vain that remedies were applied so long as the habit was persisted in; but after it became known that he pursued this pernicious practice, and he was prevented continuing it, he speedily recovered, and has been since kept in good health. We shall, no doubt, be told that thousands pursue this practice without producing epilepsy; and this is true: but how many of those thousands suffer considerable inconvenience and derangement of the functions of the nervous and digestive system, without tracing them to their true origin!"—Sir Charles Hastings, M.D., 'On the Tobacco Question.'

Homœoquackery painted by a German Journal.—The number of Homœopathic Physicians is 3254, of whom 1612 are in America. The Professorhips of the science are 5 in Germany—namely, 2 at Prague, 2 at Munich, 1 at Vienna; in the latter city, also, is one of Veterinary Homœopathy. The number of Homœopaths in Germany is 471, and 35 for animals; 21 of the former are attached to Hospitals. Of Hospitals in Germany there are only 10, and 9 of them are in Austria, 3 of the 9 being at Vienna, one being of 160 beds, another of 80, and another of 60. The journals which treat of Homœopathy in Germany are 8; 4 of them doing so scientifically, the rest for the ordinary public. The largest society of Homœopaths is in that country; it consists of 230 members, and holds annual sittings. In France there are 403 Homœopaths; in England, 244, with two Hospitals at London; in Spain, 94, with an Hospital at Madrid; in Belgium, 26; in Holland, 7; in Switzerland, 34; in Italy, 14; in the Scandinavian countries, 12; in the Danubian Principalities, 4; in Russia, 67, with a Hospital at Moscow; in Portugal, 47; in Asia, 4; and in Africa, 6. The rest are in America. In the latter country also are Hospitals at Boston, Chicago, Philadelphia; and, in addition, clinical lectures are given in many places.

The Military Hospitals of Garibaldi.—The directors of the London and Mediterranean Steam Navigation Company have announced their willingness to convey to Naples and Palermo, free of charge for freight, by their vessels from London, the packages of Medical stores and requisites contributed by many kind-hearted persons in this country for the use of the sick and wounded belonging in Garibaldi's army.

The Wounded at Naples.—The 'Times' correspondent, writing from Naples, on October 20, says:—It will be satisfactory to the benevolent in England to be assured that their donations are made good use of, and are the means of relieving great numbers of poor sufferers. I went round the various wards, in which seven or eight hundred men were in bed, and could not help expressing my surprise at the greatly improved state of cleanliness and order which exists in every part. The air was purer, the wards not so crowded, and the patients seemed more satisfied; at all events, I did not hear so many complaints as I had formerly heard. There were many cases of severe wounds, and it was touching to observe with what courage suffering is endured. One poor fellow had been shot through the chest, the ball coming out behind under his shoulder. Broken arms and legs, and the stumps of limbs, I saw resting on the water cushions which our kind countrymen have sent out, and deriving so much comfort from them that any sacrifice would have been amply repaid by the sight. In one ward I saw them changing the coarse canvas shirts of the country for the comparatively fine ones which have arrived from England—5000 in all. What a blessing for those who are tossing in fever, or are worn out with the agony of their wounds! "And these wounds," said the Doctor who accompanied us, "are all the worse that the Royalists have cut or jagged the ball before loading, in order that it may tear the flesh more. I extracted such an one yesterday."

The Progress of Vaccination.—On May 14, 1796, Jenner vaccinated a boy named Phipps, eight years old, from the hand of a dairy-woman who had the true cowpock; the boy went well through the experiment, was inoculated for small-pox in July, and failed to take it. From this time forward it was the custom to make May 14 a day of rejoicing in Prussia and elsewhere, and to publish the annual results of vaccination. For many years the vaccinations exceeded the births, showing that the people were aware of their danger while any remained unsecured. In Prussia the deaths from small-pox had averaged 40,000 annually before vaccination was introduced; and within twenty years they had shrunk to 3,000, though there had been a large accession of new territory. Sweden and Denmark, and some territories in Germany remained absolutely free from small-pox for twenty years after the practice of vaccination had been properly adopted—a sudden change from the few preceding years, when 600,000 persons died annually of small-pox in the world at large, and 210,000 in Europe; and when every quarter of a century saw twenty-five millions of human beings carried off by the foulest of distempers.—'Once a Week.'

Female Physicians.—Ladies were amongst the earliest of doctors, and some of them gave rise to a considerable amount of gossip in their day. In Chili, the Spaniards found female as well as male practitioners, with sufficient skill in both to win respect from the Europeans. That, at least, foreign "doctoresses" formed no part of the system of the Orientals, may, when we remember their jealous seclusion of women, be set down as, at all events, singular. But perhaps these might themselves spread a "soft infection," and then might be realized the sentiment of the lines—

"Non est in medico semper relevetur id æger
Interdum doctâ plus valet arte malum."

The Lectures at the London College of Physicians are to be delivered as follows during the ensuing year:—The Lumleian Lectures, by Dr Barker; Croonian Lectures by Dr Guy; and the Gulstonian Lectures by Dr Brown-Séquard. Short Courses of Lectures will also be given by Dr Garrod and Dr Lionel Beale.

M. Groux, with the congenital fissure of the sternum, is again in London. On Wednesday he gave a statement of the features of interest in his case, at Guy's Hospital, before a large gathering of students. He now performs a series of experiments upon himself, which alters the character of his *séance* from what it formerly was, and renders his case of much general interest. The experiment he repeats with the magneto-electric machine, to show, by the striking of bells, the synchronism or non-synchronism in the action of different parts of the heart and large arteries, is exceedingly ingenious and beautiful. M. Groux may rival the frog as a gift of Nature to the physiologist.

Death from an Over-dose of Colchicum.—An inquest was lately held at Bristol, on the body of a woman who had died at about ten o'clock on the previous night. The husband of the deceased deposed that she suffered from an affection in the head, which was relieved by occasional bleedings at the nose, and from rheumatism in her hands, for which she took tincture of colchicum, which had benefited him when he had taken it after suffering rheumatic pains at sea. He told her his dose was thirty drops, and knew there was a small portion remaining in the bottle he had brought from sea, though he did not know how much it was. On Sunday night his wife took the bottle, drank all that it contained, and went to bed. In the night she was affected with sickness, which turned to a bowel complaint. She vomited during the night, and again on the following day; and thinking the symptoms extraordinary, as the medicine had never so operated upon him, he sent for a Surgeon. The evidence of the Surgeon, Mr Omerod, was to the effect that the symptoms were such as would be caused by an over-dose of the tincture of colchicum. He saw her five times—twice on Monday and three times on Tuesday. She died shortly after he saw her for the last time. The Coroner, in summing up, said it seemed perfectly clear that the poor woman swallowed the tincture of colchicum as a medicine, and not with any other intention than to benefit herself, and in hope of obtaining relief from her pain; but, from a want of discretion as to quantity, she took too much, and it brought on her death. The jury returned a verdict that the woman "Died from taking too large a dose of colchicum, without medical advice."

A Resuscitated Murderer. — The following strange story appears in an American paper:—"There is now no use in concealing the fact that Albert W. Hicks, who was ostensibly executed for piracy on Bedloe's Island on the 12th of last July, is still living, though in a dangerous state, but likely to recover the full use of his faculties and limbs. The sight of his left eye is gone, and his left leg continues paralysed; but, apart from these injuries, he would appear to have suffered nothing, and his residence at his sister's house in Poughkeepsie has proved every way beneficial. It will be remembered that much comment was excited by the utterly fearless manner in which Hicks conducted himself previous to his execution. He laughed at the idea of the gallows, and was only anxious, as he repeatedly said, to have 'things conducted according to agreement.' In this agreement it is now believed that a prominent Federal officer had a part, and it is on record in the daily papers that he was present at the execution, wearing his Deputy Marshal's badge, although no longer in the Marshal's force. It was also remarked at the time that Hicks was only pulled up a distance of two feet and a half—utterly insufficient to break his neck—and that he was only allowed to remain thirteen minutes hanging. He was then cut down and pronounced dead, after which his body was immediately handed over to the care of Drs J. T. Bell and Henry D. O'Reilly, of Brooklyn. These gentlemen are responsible for his resuscitation, and the electro-chemical bath invented by Prof. Vergues was the immediate instrument. The body of the pirate was wrapped in warm blankets, and removed at once to the house of Dr O'Reilly, in Brooklyn, where Drs O'Reilly and Mellery, of this city, were in attendance. The pulse was found to be wholly quiet, but after various experiments the medical men came to the conclusion that it was only a case of suspended animation. The body was therefore at once placed in the electro-chemical bath, and while subjected to the charges of the battery and the action of the acids, Dr Crane commenced a series of experiments for the inflation of the lungs. In the course of about two hours these were partially successful, the pirate beginning to give faint indications of respiration; and these cheering signs animated the medical men in attendance to redoubled exertions. A cautery was applied to the right foot, and received answer in an immediate contraction of the leg; the same experiment was repeated under the right ear, taking care not to injure the jugular vein, and the head at once commenced rolling in a manner indicating acute feeling. Very slowly, but steadily, Albert W. Hicks regained consciousness, though for several days unable to speak, his throat being too severely injured. It was then found that his left eye—the

side on which the noose had been—had lost all power of sight, and that his left arm and left leg were utterly paralysed. In this condition he was conveyed to Poughkeepsie, where his sister, Mrs Gavan, lives; and under her roof he is now sheltered, though the friends of the family do not desire to give too much publicity to the fact."—'Express.'

THE EMPLOYMENT OF IMPERFECTLY-DISGORGED LEECHES IN FRANCE.—As long as the supply of leeches in France was derived from natural marshes, little notice was taken of the quantity of blood they might contain; but since that source of supply no longer sufficiently meets the demand, artificial marshes have been formed, so as to produce as rapid a reproduction of the annelide as possible. They are there fed by means of worn-out horses driven in among them. When they have reached a saleable size, they are transferred to a special depôt for purification and disgorgement, whence after a while they are delivered over to agents for sale. Desiring to turn their capital over more speedily, and to avoid their serious losses from escapes and depredations, the speculators have not infrequently sold out leeches still containing much blood, even sixty per cent. of their weight. So considerable had this abuse become, that the authorities have some time since interfered and prohibited the sale of any leech containing more than fifteen per cent. of undigested blood. The inspectors take any leeches they choose as samples from the receptacles in the shops or elsewhere, and having well dried them, weigh them. They then plunge them for two minutes into a tepid saline solution, and having forced out by means of longitudinal pressure all the blood they contain, again weigh them to ascertain the per-centage of such blood. Several *Pharmaciens* have of late been fined for having in their possession leeches containing more than fifteen per cent. of blood, and it has become a matter of difficulty for them to keep a supply of the animal at all without incurring the risk of such fines. Indeed, although some leeches may be found which do not contain any appreciable quantity of blood, it is stated that were all leeches to be rejected which contain more than fifteen per cent., the necessary supply could never be kept up. In fact, nothing is more irregular than the disgorging process. If the leeches are fished after remaining in the basins several months for this purpose, while some contain no blood, others still contain more or less considerable quantities. If the sojourn be still further prolonged, numbers of the leeches will die, and this, together with the losses from other causes, will greatly raise their price. It may be said that the leech-farmer should replace those leeches which contain more than the fifteen per cent.; but how is he to put this to the proof in the case of thousands upon thousands of leeches? All he can do is to determine by a well-experienced eye when the leech is fit for medical use; and it is very rare that factors will sell leeches with a guarantee that they do not contain more blood than the fifteen per cent., and some of the best merchants threaten to abandon the employment or only sell to foreign customers who are less particular. In point of fact, numerous trials have shown that leeches from the Gironde, which furnish thirty per cent. on expression, are far better adapted for medical purposes than are leeches emaciated by long fasting. Whenever we only find black blood in part digested in a suspected leech, while its physical qualities are good otherwise, it is quite fit for use. For use, a vigorous, well-nourished leech, in all the plenitude of its powers, is far preferable to an exsanguineous, half-starved annelide.—'Journal de Chimie Médicale,' 1860, p. 425.

DRAWING-ROOM EARTHQUAKES.—This drawing-room earthquake may be easily produced by a single pair of feet in vigorous movement to and fro from toe to heel, and if the feet be worked alternately in a room of some extent a very powerful vibration may thus be created, and sustained with a very little practice, as any one may ascertain by experimenting. If the performer has thin soles and no heels, he will be able to accomplish this on a soft carpet almost without noise, and he has simply to desist when attention is directed to his feet; or if a lady is the source of the earthquake, her crinoline will conceal her pedal play. Any of my readers with average muscular power, and a slight amount of exertion, may produce such earthquakes in any drawing-room in London, and no one whose mind is not sedulously prepared beforehand will dream of attributing them to spiritual agency.—'Once a Week.'

APPOINTMENTS FOR THE WEEK.

Wednesday, November 7.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

OBSTETRICAL SOCIETY OF LONDON.—8 p.m.

Thursday, November 8.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.

London Surgical Home.—2 p.m.

Friday, November 9.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, November 10.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, November 12.

Operations at the Royal Free Hospital, 2 p.m.; Metropolitan Free Hospital, 2 p.m.

ROYAL INSTITUTION.—2 p.m.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—Clinical Lecture on "Epilepsy and Paralysis," by Dr Brown-Sequard, 4 p.m.

MEDICAL SOCIETY OF LONDON.—8½ p.m.

Tuesday, November 13.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

First Step in Chemistry. By Robert Galloway, F.C.S. Third Edition. London: John Churchill.

On Gout. By Wm. Gairdner, M.D. Fourth Edition. London: John Churchill.

The Healthy Urine of Man. By the Rev. Samuel Haughton, M.A. Dublin: Printed at the University Press by M. H. Gill.

NOTICES TO CORRESPONDENTS.

MEDICUS.—Mr Baker Brown has performed the largest number of operations for vesico-vaginal fistula of any man in this country. Why there should be a desire to depreciate his success, we cannot say. His operations at the Surgical Home are worth attending. We have no doubt that any Practitioner properly applying would be admitted.

H. W.—It cannot be effected.

A SUBSCRIBER.—We are sorry that we cannot insert the communication forwarded.

Mr FOWLER.—1st. Yes.—2nd. No.

Mr BLAKE is thanked.

ASTERISK.—Newspaper received. We are obliged to our Correspondent for his suggestions.

E. B.—Your opinion is quite correct. There is no such restriction.

A SURGEON.—It is extremely doubtful whether the pus-globule is actually absorbed in cases of pyæmia. Lebert's views are probably correct, that the deposits, so called, are not truly deposits, but the results of a state of inflammation. Under the microscope, a small injected spot is first seen; and subsequently, in the centre of the vascularisation a drop of pus is manifested. The vascularity then declines, and the purulent collection increases. There are cases of pyæmia in which no primary abscess was discoverable. This countenances Rokitansky's view, that pyæmia may occur as a primitive affection, or as a special crasis of the blood. When absorption takes place from an abscess, it is not probably an absorption of a pus-globule, but of a pyogenic fluid: in short, pyæmia admits of several explanations. Mr Lee has shown that a debilitated state of the system has an important share in developing this condition. The Birkenhead case is thus easily explained.

A STUDENT.—1st. No.—2nd. Write to Mr Belfour.

A COUNTRY SUBSCRIBER.—It shall be attended to.

Mr GRIFFIN.—Received.

Dr TUCKER.—Received and inserted.

INQUIRER.—Nothing has yet been done with the handsome bequest by the late Mr Morley to St George's Hospital. It would be a noble opportunity to establish an extra-urban hospital, and we hope the intention will soon be realised.

CHIRURGUS (Plymouth.)—The connection of diabetes with cataract is well established—not so the connection of the latter with rheumatism. We may observe, however, that Dr Richardson has shown that rheumatism depends upon the presence of lactic acid in the blood.

H. J.—We have not yet received the volume.

VIATOR.—Enclosures received. Very bad!

A FATHER.—It will not be overlooked.

AN OLD SUBSCRIBER.—1st. No.—2nd. No.—3rd. No.

W. B. S.—The machines are, we believe, as useful as others invented for the same purpose; but we cannot express an opinion as to the general usefulness of such appliances.

Mr DENNIS C. O'CONNOR.—Communication received, and will be attended to.

JUSTUS ET TENAX, on the Educational Regulations of the Medical Council, received. We think it wrong that these regulations should be made retrospective.

AN INDIAN SURGEON is thanked. The papers will be useful.

M.R.C.S. & L.A.C.—Mr Moore, the agent, will be able to procure you such a situation as you desire.

A Perusal of all the New BOOKS and NEW EDITIONS as soon as published, for ONE GUINEA PER ANNUM.

LEWIS'S MEDICAL LIBRARY,

15 GOWER STREET NORTH.

Books may be retained as long, or exchanged as frequently, as suits the convenience of Subscribers. Prospectuses gratis on application.

Medical Clubs, in Town and Country: from Two to Ten Guineas per Annum.—New Books supplied at 20 per cent. discount.

A Book about Doctors, 2 vols., and all the new MEDICAL BOOKS, in unlimited supply, at

LEWIS'S MEDICAL LIBRARY,

15 Gower Street, North.

SINGLE SUBSCRIPTION, ONE GUINEA PER ANNUM.

Now ready, price 5s. 6d.,
or free by post to any part of the United Kingdom, price 6s.
Fourth Edition, greatly enlarged and improved.

A Grammatical Introduction to the LONDON PHARMACOPŒIA, and a KEY to PHYSICIANS' PRESCRIPTIONS. By S. F. LEACH.

"This little work will be found extremely useful to students who have received but an imperfect classical education."—'The Lancet.'

Hughes and Butler, Medical Booksellers and Publishers, 15 St Martin's-le-Grand

Bull's Library.—All Subscribers to this Library have the choice of above 50,000 of the best Works in History, Biography, Philosophy, Religion, Poetry, &c., in the English, French, German, and Italian Languages. Subscription, One Guinea a Year and upwards. Prospectuses supplied gratis.—BULL'S LIBRARY, 19 Holles street, Cavendish square, W.

Cheap Books at Bull's LIBRARY.—SURPLUS COPIES of "Kingsley's Miscellanies," "McClintock's Arctic Voyage," "Friends in Council," "Trollope's West Indies," "De Quincey's Works," and many other books, are now ON SALE, at greatly-reduced prices. Catalogues sent gratis and post-free.—BULL'S LIBRARY, 19 Holles street, Cavendish square, W.

Imperative Sale of Clocks OF EVERY DESCRIPTION, WATCHES, GOLD CHAINS, AND JEWELLERY.—In consequence of REMOVAL to 135 REGENT STREET, the select and first-class Stock of the above is now exhibited and marked off in plain figures, at from 30 to 50 per cent. reduction. The opportunity is short (only during the necessary alterations in the new premises), and to any purchaser is worth a journey.

ARNOLD, Watchmaker, 69 RED LION STREET, HOLBORN.

GAS STOVES,

GASELIERS, AND GAS FITTINGS OF ALL KINDS, FOR CHEMISTS, &c.

H. MATHER,

18 HIGH HOLBORN.

Vacancy in the Editorship of the BRITISH MEDICAL JOURNAL.—As the office of Editor of the British Medical Journal will become vacant on the 31st of December next, it is requested that all Candidates for the appointment will communicate, not later than the 17th of November, with Dr WILLIAMS, of WORCESTER, and forward to him, with their Testimonials, the Scheme they propose for Conducting the Journal.

CHARLES HASTINGS, Knt., M.D., &c.,
President of Council.

Worcester, Oct. 23, 1860.

Surgical Instruments.—J. ARNOLD continues to supply Instruments of the best workmanship at moderate prices, manufactured on the premises under his own superintendence.

J. ARNOLD, 35 and 36 West Smithfield, E.C.
Established 1819.

Elastic Supporting Fabrics, of very superior textures, for Varicose Veins, Accouchement, Spinal Affections, Hernia, &c. Instructions for measurement, and prices on application to the Manufacturers, POPE and PLANTE, 4 Waterloo place, Pallmall, London, S.W.

For Infants.—The British FEEDING BOTTLE (registered) may be placed in any position without the food running out. The supply can be regulated by a stop-cock; being electro-plated, it may be instantaneously cleaned. Unlike wood, ivory, or bone, it is impervious to moisture, cannot crack or become sour; there is no possibility of the infant drawing air with the food.

By W. T. COOPER, Pharmaceutical Chemist, 26 Oxford street, London.

Price 7s. 6d., or free to any railway station, 8s. 6d.

Chlorodyne. — R. Freeman,

Pharmaceutist, Kennington road, London, S., informs the Profession and Trade that he has FOR YEARS MADE, and extensively used in his business, Chlorodyne; and that he is supplying it in one-ounce stoppered bottles at 1s.6d. each, and in four-ounce bottles, 5s. each. He guarantees it to be uniformly and properly-prepared, and superior to any other makers', though their charge be ever so exorbitant; and he trusts that the lowness of price at which he offers it will allow the Profession to use it in common practice and at public institutions, so that its extraordinary beneficial effects may be enjoyed by the poorest sufferer. Sold by all Wholesale Druggists.

WATER MATTRESSES & CUSHIONS,

For Bed Sores, Consumption,

Paralysis, Fevers, and all Invalids and Bedridden Patients. Air Cushions and Pillows, Bed Sheets, Elastic Stockings, Enemas, Ear Trumpets, Railway and Bed Urinals, Bed Pans and Slips, &c.

WILLIAM LEE, 115, NEW BOND STREET, W.

Water Beds on Hire, 7s. per Week. Deposit, £10.

TO THE PROFESSION.

Messrs M'Gowan & Danks

(THE PRINTERS OF THIS JOURNAL)

Are prepared to forward Estimates, to those requiring the same, for any description of Work connected with the Printing Business.

Messrs M'G. and D. are enabled, from the facilities which they possess, to execute whatever may be entrusted to them with economy and despatch.

Letters addressed to No. 16 GREAT WINDMILL STREET, HAYMARKET, will meet with immediate attention.

*** There is at the present time an opening for the Printing (and Publishing if wished, of a Weekly Periodical.

Kinahan's LL Whisky v.

COGNAC BRANDY.

This celebrated old IRISH WHISKY rivals the finest French brandy. It is pure, mild, mellow, delicious, and very wholesome. Sold in bottles, 3s. 6d. each, at most of the respectable retail houses in London; by the appointed agents in the principal towns in England; or, wholesale, at 8, Great Windmill street, Haymarket.—Observe the red seal, pink label, and cork branded "Kinahan's LL Whisky."

Catalogues gratis.

Bank of Deposit, Estab-

LISHED A.D. 1844, 3 PALLMALL EAST, LONDON.—CAPITAL STOCK £100.000.

Parties desirous of INVESTING MONEY are requested to examine the Plan of THE BANK OF DEPOSIT, by which a high rate of interest may be obtained with ample security.

Deposits made by Special Agreement, may be withdrawn without notice.

The Interest is payable in January and July.

DINNEFORD'S

Pure Fluid Magnesia,

now greatly improved in purity and condensation. "Mr Dinneford's Solution may fairly be taken as a type of what the preparation ought to be."—'Pharmaceutical Journal,' May, 1846.

This excellent remedy, in addition to its extensive sale amongst the public, is now also very largely used for DISPENSING. In the stone jars (half-gallon, 5s. 6d.; gallon, 9s. 6d.,) specially adapted for the use of Surgeons and Chemists. To be had from the Manufacturers,

DINNEFORD and CO., Chemists, 172 Bond street, London; all Wholesale Druggists and Patent Medicine Houses.

PULVIS JACOBI *VER.*, NEWBERY'S.

GENTLEMEN,—We beg to call your attention to the following paragraph by "*J. Cheyne, M.D.*, Physician to the Hardwicke Fever Hospital, Dublin, *in his paper on the virtues of James' Powder in the Apoplectic Diathesis*:"

"She began a course of James' Powder in the latter end of September: the first night she took only two grains, and every succeeding night an additional half grain, till the dose amounted to twenty grains. She took *twenty grains every night for five weeks*, when she found herself so well that she discontinued the medicine."—"*Dublin Hospital Reports*," *vol.* 1. *p.* 319.

To secure the dispensing of the *original* preparation, which, for 114 years, has been sold by the Newbery family in St. Paul's Churchyard, it is necessary to prescribe it as "*Pulvis Jacobi* Ver., *Newbery's*," otherwise another article (wanting in the best properties, and recommended to be given in a different code of dose, *though called by the same name*), will be substituted for the original medicine. This, of course, cannot but have an effect other than that expected, and will thereby lead the practitioner totally to discard it from his daily Pharmacopœia, as a preparation whereon no dependance can be placed. We hope the above extract will prove that when the genuine medicine is used, faith may be reposed in it.

Yours faithfully,

F. NEWBERY & SONS.

45, St. Paul's Churchyard.

S. Bowles (late Windsor and

Co.), PHIAL and BOTTLE MERCHANT, Dealer in Druggists' Sundries, &c., 6 James street, Covent garden, W.C. The cheapest house in London for every description of MEDICAL GLASS of the best quality.

TEETH WITHOUT SPRINGS,

BY HER MAJESTY'S ROYAL LETTERS PATENT.

Newly-invented Applica-

TION of PREPARED INDIA-RUBBER in the construction of Artificial Teeth, Gums, and Palates.

MR EPHRAIM MOSELY,

SURGEON-DENTIST, 9 GROSVENOR STREET,

SOLE INVENTOR AND PATENTEE.

A new, original, and invaluable invention, consisting in the adaption, with the most absolute perfection and success, of CHEMICALLY-PREPARED INDIA-RUBBER, in lieu of the gold or bone frame. The extraordinary results of this application may be briefly noted in a few of their most prominent features:—All sharp edges are avoided; no springs, wires, or fastenings, are required; a greatly-increased freedom of suction is supplied; a natural elasticity, hitherto wholly unattainable, and a fit perfected with the most unerring accuracy, are secured; while, from the softness and flexibility of the agent employed, the greatest support is given to the adjoining teeth when loose, or rendered tender by the absorption of the gums. The acids of the mouth exert no agency on the Chemically-prepared Indie-rubber, and as it is a non-conductor, fluids of any temperature may be retained in the mouth, all unpleasantness of smell or taste being at the same time wholly provided against by the peculiar nature of its preparation. Teeth filled with gold, and Mr Ephraim Mosely's Cement, the only stopping that will not become discoloured, particularly recommended for front teeth.—9 Grosvenor street (W), London; 14 Gay street, Bath; 10 Eldon square, Newcastle-on-Tyne.

The Roman Thermo-

ELECTRICAL BATH. By J. TUCKER, M.D. Price 6d., from the Author, at Sligo.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM,

32 SOHO SQUARE, LONDON, W.

October 22nd, 1860.

Notice.—The Copy of the

MEDICAL REGISTER to be printed and published in 1861, as directed by the 27th Section of the Act, will contain those Names only which appear on the General Register as existing on the 1st day of January, 1861.

It is particularly requested that claims for the Registration of first or additional Qualifications, and Notices of Alteration of Residence, may be sent to this Office as soon possible.

United Kingdom Life

ASSURANCE COMPANY, No. 8 WATERLOO PLACE, PALLMALL, LONDON, S.W.

The Funds or Property of the Company, as at 31st of December, 1858, amounted to £652,618 3s. 10d., invested in Government or other approved Securities.

CHAIRMAN.—The Hon. FRANCIS SCOTT.

DEPUTY-CHAIRMAN.—CHAS. BERWICK CURTIS, Esq.

INVALID LIVES.—Persons not in sound health may have their lives insured at equitable rates.

ACCOMMODATION IN PAYMENT of PREMIUMS.—Only one-half of the Annual Premium, when the Insurance is for life is required to be paid for the first five years, simple interest being charged on the balance. Such arrangement is equivalent to an immediate advance of fifty per cent. upon the Annual Premium, without the borrower having recourse to the unpleasant necessity of procuring Sureties, or assigning, and thereby parting with his Policy, during the currency of the Loan, irrespective of the great attendant expenses in such arrangements.

The above mode of Insurance has been found most advantageous when Policies have been required to cover monetary transactions, or when incomes applicable for Insurance are at present limited, as it only necessitates half the outlay formerly required by other Companies before the present system was instituted by this Office.

LOANS are granted, likewise, on real and personal Securities.

FORMS OF PROPOSALS, and every information afforded, on application to the Resident Director, 8 Waterloo place, Pallmall London, S.W.

(By Order) E. LENNOX BOYD, Resident Director.

Newton Wilson and Co.'s

World-famed PATENT.—THE NEW PATENT NURSING CHAIR, in which the child nurses, amuses, exercises, and weighs itself, is a marvel of ingenuity and utility, unanimously recommended by the Press and the Faculty. No family should be without one. Price 12s. 6d. upwards. Prospectus free.

WILSON'S PATENT CARPET SWEEPER, which cleans a carpet thoroughly without labour, without injury, and without raising a grain of dust. Price 15s.

Newton Wilson and Co., 144 High Holborn, London.

Important to Surgeons.—

The old-established and well-known Business of JOHN MILLIKIN, now MILLIKIN and LAWLEY, 161 Strand, adjoining King's College.—A change in the proprietorship offers to Surgeons the opportunity of purchasing any kind of Instrument from this well-manufactured stock, which cannot be surpassed in style, quality, or price.

Messrs MILLIKIN & LAWLEY beg to draw the attention of their friends and customers to the superior stock of Mathematical Instruments, their great variety of Cutlery, and the selection of first-class Microscopes, Opera and Race Glasses.

A great variety of Skeletons, Skulls, Hands, Feet, &c., of superior quality, at moderate charges.

Every description of Surgical Instruments made to order, with the utmost PRECISION and DESPATCH.

Surgical Instruments and Cutlery Repaired Daily.

Liquor Castanea Equina.—

Messrs. REW and Co. respectfully solicit the attention of the Profession to this Preparation of the Horse-Chesnut; taken internally for Rheumatic Gout and Rheumatism, it is a safe, agreeable, and most efficacious remedy.

Dose, two to four drachms. Price 12s. per pound.

The Oil of Horse-Chesnuts applied externally for enlarged and stiff joints, acute or inflammatory pain of any kind, gives almost immediate relief.

These genuine Preparations of the Horse-Chesnut are prepared only by REW and CO.

LITHIA WATER, LITHIA POTASH, and LITHIA AMMONIA WATER. These Waters are prepared according to the Instructions of Dr Garrod, and each bottle is guaranteed to contain the proper proportion of Lithia. 5s. per doz.

PATHOLOGY OF THE SYMPATHETIC NERVES.

By JAMES RORIE, M.D.

II.—Centric Paralysis (Fever).

There is an affection of the system, the analogy between which and inflammation has long been observed, and which, from the similarity of its symptoms, has received a somewhat identical name—I refer to *fever*. The analogy has, however, as yet gone no farther than the symptoms; for while inflammation is described as a condition presenting the phenomena of redness, heat, pain, &c., "fever," says Wood, in his 'Practice of Physic,' "is an acute affection of the system, in which all the functions are more or less deranged, the most striking phenomena being sensorial and nervous irregularity, increased frequency of pulse, increased heat, and disinclination for food." This, however, instead of being a definite condition, is merely a list of symptoms.

What, then, really is fever? Inflammation I have endeavoured to show to be (instead of heat, pain, redness, &c.) phenomena the result of local paralysis of the sympathetic system; so here I trust I shall be able to prove that fever, instead of the indefinite mass of symptoms already mentioned, is in reality phenomena resulting from centric or general paralysis of the sympathetic.

The analogy which we have already seen to exist between the two nervous systems, holds also here in a remarkable manner. An affection of a cerebro-spinal nerve produces loss of function of the skin and muscles which it supplies; an affection of a portion of the sympathetic produces loss of function of the capillaries, &c. (inflammation); an affection of the brain and spinal cord—*i.e.*, the cerebro-spinal centres—produces general loss of function of the motor and sensory organs; an affection of the sympathetic centres produces general paralysis of the nutritive functions of the body (fever).

In the following description, we will follow the same course with regard to fevers which we have done with reference to inflammation, and first consider what facts we have to deal with before entering on any theory.

But at the very outset there are difficulties which appear at first sight insurmountable. Fevers differ so much from one another, that it will appear absurd to ascribe them all to the same cause. This difference, however, I believe to be due to a dissimilarity of the exciting causes, namely, the hypothetical poisons; while what we may term the proximate cause, namely, the changes in the body which immediately give rise to the phenomena termed fever, is the same—viz., general paralysis of the sympathetic system. But this complexity is rendered still more complex, in consequence of the exciting cause which has led to the proximate still continuing to operate on the phenomena resulting from the proximate cause. This may be rendered more intelligible by an example. A poison (?), say the rubeolar, entering the body of a child, acts as an exciting cause, and produces the proximate cause—paralysis of the sympathetic nerves—which, in its turn, gives rise to the phenomena known as fever; but the poison (the exciting cause) has a tendency to pass off more immediately by the respiratory passages, thus giving rise to the coryza, one of the chief characteristic symptoms of measles.

We have thus two classes of facts to consider: 1. The phenomena common to all fevers—*i.e.*, the phenomena resulting from the proximate cause, and with which we have at present only to do; and 2. The special phenomena of fevers—*i.e.*, phenomena depending on the action of the exciting causes, and to which I shall only refer in so far as may be necessary to support the views here advocated.

1. *Phenomena common to all Fevers.*—The progress of a fever, as the term is understood by writers on general pathology—that is, the phenomena which occurring in the human subsubject constitute a febrile condition—is usually divided into four stages. Thus, according to Wood, we have (*a*) the forming stage; (*b*) the cold stage; (*c*) the hot stage; and (*d*) the declining stage. As, however, the first stage is more or less intimately connected with the second, and belongs in a great measure to the special phenomena, we will divide the progress of a fever into (*a*) the stage of accession; (*b*) the stage of fever proper; (c) termination in death or recovery.

(*a*) On a person commencing to suffer from fever, he becomes conscious at first only of a sense of weariness and confused pain in his limbs, &c.; depression of spirits, disturbed sleep, &c.; and then a feeling of chilliness. "This," says Wood, "is the first decided step in the febrile movement. There is usually at first a greater sensitiveness of the surface to the impression of cold, so that a current of cool air, or the contact of a cool body, produces a sense of chilliness which runs momentarily through the frame and then subsides. The feeling of cold, however, soon becomes more permanent, and quite independent of surrounding objects, beginning most commonly in the back, and extending to the limbs and over the body, producing rigors, shivering, chattering of the teeth, and sometimes universal tremors and even shaking, though the patient may be near a fire, or covered with blankets in bed. In general, the sensation of chilliness is attended with a positive reduction of temperature upon the surface, especially in the extremities." The pain now increases greatly in the back, loins, and head; "sensibility is often diminished, and the mental functions impaired; and even delirium occasionally occurs."

"The circulation, which even before the commencement of the cold stage is often languid, now becomes obviously depressed; the pulse is weak, small, often irregular—sometimes more frequent, sometimes less so, than in health; the capillary circulation is slow and feeble; the face is pale, the features often shrunk, the skin generally pale and contracted, with the appearance of goose-flesh; and, in very bad cases, the fingers are sometimes shrunk and wrinkled as after long immersion of the hand in water. There is often a purplish or bluish appearance in the hands and feet, especially about the finger and toe nails, arising from stagnation of blood in the capillaries.

Other symptoms of functional derangement show themselves in this stage: "the respiration is short and somewhat hurried, and both the breathing and pulse are accelerated by muscular exertion. Nausea and vomiting often occur during the chill, attended with thirst, and a dryish, clammy state of the mouth and fauces."

The duration of this stage varies in different fevers from a few minutes to several days. It may even prove fatal at the very first, but usually terminates in

(*b*) *The Stage of Fever Proper.*—"The symptoms of the chill," says the Author already quoted, "usually pass by degrees into those of the hot stage. The coldness subsides, and is succeeded by a sense of heat which is at first not uncomfortable, but soon becomes excessive and distressing. The sensation of heat is not confined to the surface, but extends also to to the internal organs. Nor is the sensation delusive: the surface feels hot to the hand of another, and an elevation of temperature is indicated also by the thermometer, which, when placed under the tongue, rises in some instances as high as 107 deg. At the same time that the heat increases, the circulation is often accelerated to 110 or even 130 beats per minute. Violent head symptoms now show themselves: the face is flushed, the head painful, the senses usually more acute, and the mental functions disordered; the eyes are painfully sensitive to light, and the ears to sound; and both vision and hearing are usually sharpened. The senses of taste and smell are also impaired.

"The digestive organs are always disordered, the appetite is entirely lost, and there is generally a disgust for food and for warm drinks. Nausea and vomiting are not infrequent; a disagreeable taste in the mouth is common; and the tongue is almost always covered with fur, which is usually at first thin and white, then thickens and becomes yellowish, and sometimes assumes a brown or blackish colour. The end and the edges of the tongue, when not coated, are generally redder than in health. The bowels participate in the general disorder of the alimentary mucous membrane, being affected for the most part with constipation or diarrhœa; and the discharges are almost always unhealthy, either in colour, odour, or consistence. The secretions are always deranged in fever. When the disorder is at its height, they are usually deficient; hence the dry skin, the burning eye, the dry tongue and mouth, the constipated bowels, the scanty and high-coloured urine. In other conditions of fever, especially in its decline, or when its violence has so far remitted as to permit the secretory organs to resume their function, the quantity secreted is often in excess; hence the copious perspiration, the serous and bilious diarrhœas, and the profuse discharges of urine which occur under the circumstances mentioned. The character as well as the amount of the secretion is also changed. The breath and perspiration often acquire a disagreeable odour, the urine is changed in colour and consistence, and the bile discharged from the stomach and bowels is seldom quite healthy in appearance. The respiration, which in the primary stage is short and hurried, becomes more free when the fever is fully developed, but still remains frequent; and there is very often a short, dry cough." This stage, like the preceding, may continue for a longer or shorter time, when it terminates in

(*c*) *The Stage of Termination.*—When fever begins to decline, the change is often marked by the occurrence of some spontaneous evacuation—such as profuse perspiration, increased urine, bilious or serous discharge from the bowels, or hæmorrhage. Occasionally along with some one of these discharges, or in place of them, one or more abscesses form in various parts of the body, often containing large quantities of pus. By far the most frequent of the evacuations which attend the decline of fever is perspiration.

(To be continued.)

ON THE NON-DIGESTION OF FAT,

CONSIDERED IN ITS SPECIAL CORRELATION WITH AFFECTIONS OF THE PANCREAS.

By Dr E. ANCELET, of Vailly-sur-Aisne.

(*Translated for the Medical Circular.*)

(Continued from page 304.)

A *résumé* of these thirty cases presents us with the following facts:—

The fat may, on its expulsion from the intestine, be either in a liquid state or solid, or in both these forms at the same time. In 14 cases its physical state is not noticed. But, be it as it may, it presents the general characters of fat, melts with heat and congeals with cold, is inflammable, &c., and, in a word, does not seem changed in its composition. It may be expelled by itself, or with fæcal

matters; and these may be liquid or solid, and in 9 cases were colourless. The evacuation takes place with pain or without. It is seen every day, or after intervals of some days, or it has its remissions. This phenomenon shows itself for a week, several weeks or months, a year or two, or even thirteen years. The daily quantity of fat observed in 4 cases varied from 1 to 9 ounces: in 4 other cases it is only said to have been considerable. The patients had at the same time attacks of colic, pains in the region of the liver, and diabetes. Six were icteric. In 5 cases the patients were cured, and Haller's patient recovered after the expulsion of a biliary calculus. In 9 cases the result is not stated: 16 of these patients died, 3 of whom are said to have been marasmic; and marasmus is incidentally mentioned as affecting several others. In 1 case the intestine was thickened and ulcerated; in another, the liver was fat and the gall-bladder contained bile; while in 1 it was diseased, though care was not taken to ascertain the nature of the lesion. In 5 cases the pancreatic and biliary ducts were obliterated either by scirrhus or calculi of the pancreas. In Bright's case the pancreas was cancerous, but the ductus choledocus remained permeable. The obliteration of the pancreatic canal is merely noticed in 3 cases. Lastly: in another, the pancreas, stomach, and duodenum were inflamed; the liver was sound.

It will be recollected that Bright, by a process of exclusion, (*a*) came to regard stearrhœa as a symptom properly belonging to affections of the pancreas—an approximation made by Kuntzman a dozen years before. M. Moyse, who collected and classed eighteen of the cases we have cited, and M. Bernard, when he declared it to be a pathognomonic sign, saw in it a proof of the digestive action which the prancreatic juice has on fat aliment; and these facts seem the more conclusive that they preceded the physiological theory.

To appreciate fairly the value of this argument, let us consider the following questions. Are fatty evacuations seen where the pancreas is sound? An important point to be cleared up before any other, would be to determine, if I may so speak, the digestive capacity for fat, and to ascertain whether, when the quantity of fat is considerably increased, and which an animal digests in twenty-four hours, for example, the whole is absorbed, or whether a part escapes without being digested, and in what proportion. Bernard contented himself with once submitting a dog, in good condition, to the regimen of those in which he had destroyed the pancreas: the kidneys contained no fat. The demonstration is insufficient; since a cat fed two or three days on pure fat, had fat both in the large intestine and in the cæcum.

I directed a man in good health to take 100 grammes of olive oil, but to change nothing of his ordinary diet. This produced three liquid stools in which was contained an oily substance. But I shall not here enter into further details, as I propose to institute a series of experiments in the view of noticing more closely these phenomena. At present, however, we must conclude that there are two kinds of stearrhœa;—one normal, depending exclusively on a superabundance of fat in the aliment; and the other pathological, produced by disturbance in the function of digestion. Viewed in this light, the cases of Rivière (and of Babington) cease to be pathological.

In the cases of stearrhœa recorded by Pearson and Prout, where there was no excess in the ingestion of fat, no mention is made of any morbid alteration of the pancreas, which was not examined, probably, with all the care requisite. The retention of bile, noticed in two of these cases, and which is the necessary consequence of the slightest alterations in this organ, permits at least the supposition that that organ was not sound. We must not be too much of materialists even in pathological anatomy. The anatomical must be placed side by side with the pathological lesions, if such be their proper denomination—lesions of relation, which, by influencing the neighbouring parts, without attacking the organ itself, disturb its functions, and interfere with the normal and free discharge of the pancreatic juice. The solution of this—the first question—is therefore doubtful.

The second question comes next to be considered. Is stearrhœa ever absent when the pancreas is affected? At the autopsy of a man, thirty-five years of age, Hull found the pancreas almost destroyed by the pressure of two abdominal tumours. This man died in a state of marasmus. The cystic and pancreatic ducts were almost obliterated at their duodenal insertion, and the duodenum had begun to suffer change. Hull *was informed* that no fat had been found in the fæces. This case is evidently of no value, for the examination of the fæces was not such as to enable us to assert that fat was absent: we class this case, therefore, with a numerous list of similar cases, which we have in view, where this symptom was neither alluded to nor looked for. According to Bernard, Fearnside cites several cases of acute affections of the pancreas in which stearrhœa did not shew itself; which, says this expert physiologist, may to a certain extent be accounted for by abstinence from food, and, therefore, owing to the non-reception into the large intestine of fat materials. From want of precise information as to the regimen enjoined these patients, it must be admitted that this argument is not wanting in probability, and that facts, too, tend to its confirmation. Thus, in Kuutzman's patient the fat increased when the diet consisted of meat. In Bright's case, the fatty dejections, which had been noticed for a length of time, came first under the eye of the observer after the patient had taken a dose of castor-oil. In Gross's case, they appeared when the patient took fat, and disappeared when its use was discontinued. Are we in this way to account for those remissions, sometimes prolonged, that have been opposed to the physiological theory, and noticed in cases where the pancreas was so diseased that it could no longer discharge its function? But if viewed in this light, Clark's case may be opposed, in which modifications of aliment seemed to have no influence on the presence of fat. Moreover, we may say with Tiedmann, that, in certain cases at least, the quantity of fat excreted is greater than the quantity taken with the food: must it come, then, from some other source; and must the appreciations of observers be inaccurate?

The third question regards pathological stearrhœa. Is it the consequence of alteration in the pancreas, or of alteration in some other organ—of the liver, for instance, as M. Longet seems disposed to believe? The intimate anatomical relations that exist between the pancreatic and biliary ducts, which, in some way or other, renders the one responsible for the other, encumbers this question with a degree of obscurity which facts and recorded experiments seem incapable of dissipating. In the numerous cases which we have passed in review, we see, in fact, that affections of the pancreas are very often accompanied with retention of bile—a material cause of icterus, which will, perhaps, appear to be still more frequent when it comes to be considered more closely. Without going beyond the imperfect cases cited in this chapter, the afflux of bile was at least in ten cases impeded; and it cannot be concluded from the other cases, in which no notice of this is found, that it did not exist. If in any case it be said that the biliary duct was still permeable, I own that the solitary fact makes on my mind but a slight impression. The patient was icteric—a circumstance to be noted—but other cases which we have collected serve to put us on our guard against that cause of error. Thus, in M. Rostan's case, among others, the biliary duct, when isolated, allowed passage to the bile; but when pressed on by the hypertrophied head of the pancreas, there was interruption to its flow. If affections of the pancreas are not only a frequent cause, but an inevitable source, of dyscholia; do not artificial affections, such as inflammation produced by experiment, give rise to similar effects? This objection has been so little heeded by experimentalists, that not one of them has in a satisfactory manner stated the condition of the biliary apparatus; nor have they, seemingly, examined the state of the sclerotic. As to the colourlessness of the fæces, which, when ascertained, might serve as an index, it has seemed enough to explain it by an hypothesis perfectly gratuitous. "It is remarkable," says M. Bernard, "that bile communicates to the matters with which it comes into contact a bright yellow, but with pancreatic juice gives a deep brown tint. Hence the pancreatic juice contributes indirectly to the colour imparted to the fæces. In icterus the fæcal matters are colourless, but for an inverse reason." For our own part, and until a contrary proof can be adduced, we shall see in this fact nothing more than a symptom of dyscholia. Reciprocally, the silence of observers as to the state of the pancreas, and even, as we have said, the affirmation that it was sound, and the presence of a calculus in the biliary ducts, can be no demonstration that fatty dejections have an exclusive connection with suppression of the biliary flux. Thus, in Haller's case, the calculus impacted in the ductus choledocus must at the same time have occasioned obstruction of the duct of Wirsang. These considerations, seen in the light of experimental physiology, have a high importance; for if this reciprocity of action, that binds them *in solidum*, be taken into account, it will no longer be allowable to conclude anything from the experiments of Bidder, Smith, and Schelbuch, undertaken to prove that obstruction to the course of the bile hinders the digestion of fat. It is the same with those of M. Bernard as regards the pancreatic juice; and the problem may be said to be still unsolved, if, rather, it be not incapable of solution.

Marasmus, noticed in most of the cases where there has been disease of the pancreas, is another argument adduced to prove the non-digestion of fat. This, unquestionably, is the general fact, and, according to Pemberton, emaciation takes place more rapidly, is more decided, and advances with quicker step, in patients suffering from affections of the pancreas than in any other. Let us observe here, in passing, that this emaciation, which has in it nothing extraordinary, may be propagated from the mother to the fœtus, of which, however, we have seen but one instance. The infant was scarcely more than a skeleton.

But M. Longet opposes cases of profound changes in the pancreas in subjects who showed little or no emaciation—examples taken from Casper, Greisel, Abercrombie, de Haen, and Davidoff; to which we may add those of Harlhman and Tacheron, though in this last example it may be objected that the cancer occupied only the tail of the pancreas, and that the functions of the rest of the gland were not interfered with. Should these cases, few in number, be regarded only as exceptions that do not affect the general rule, it should also be observed that those of Abercrombie and Casper belong to the category of those

(*a*) An admirable procedure, which, in difficult diagnostic investigations, often leads to sound inference, if not to certainty, though less absolute, possibly, than that obtained by those geometricians who, according to Dr Wallis, "allow the method of exhaustions to be good demonstration."—Translater.

rare cases where cancer affects the pancreas only.

We shall now, by way of general conclusion, remark, that by submitting physiological experiments to the control of pathological facts, and discussing them in a rigorous manner, we see the deductions that have been drawn from them invalidated by causes of error; and we no longer observe that neatness in the demonstrations—presented with raro talent—which before struck us so vividly. The whole has to be reviewed; and, if allowed to express our wishes, we would say that whoever would, in physiology, appreciate in a conclusive manner the difference between the action of bile and that of the pancreatic juice in the process of digestion in the living animal, should be assured that the means for preventing the flow of one of these fluids should not indirectly hinder the afflux of the other; and that these conditions once fulfilled, in order, for example, to demonstrate the non-digestion of fatty materials, it is not sufficient to discover fat in the fæces, but the digestive capacity for fat in a given time in the normal state, and in a given time, must be first ascertained, as well as the quantitative variations which such and such a lesion may produce.

Pathology should be restricted to similar conditions; and the digestion of fat once ascertained, is its digestion due either to medicines or aliments? If the alimentation is at least normal, and no longer accounts for the presence of fat in the fæces, the case is pathological, and there is diminution or entire loss of the special digestive faculty. Under what conditions, next, does stearrhœa show itself? Do its intermissions, where they are seen, correspond strictly with the modifications of the regimen, and can it be modified by therapeutic agents? In cases where the autopsy can be accomplished, what are the anatomical or physiological lesions to which this symptom can be referred? I must own, in concluding, that it is almost with sadness that I give utterance to these negative conclusions, which will take away, perhaps, all sort of interest from a work I began nearly six years ago, and have since pursued in the midst of difficulties. But it is not serving science the less to show the weak side of things, whether it be by reducing to their true value propositions that have not been sufficiently weighed, or by provoking to new investigations, and new proofs for confirmation, and giving them definitively the right of citizenship. Should doubt only come out of these discussions, doubt would be far better than erroneous belief; and should our mission be confined to clearing up ground for a foundation, rearing the edifice may be the work of futurity.

ON SUB-MAXILLARY ADENITIS,

RESULTING FROM DENTITION.

By Dr GOURIET, of Niort.

There is not in the province of Medicine or Surgery a subject so common as not to present points of interest when pursued into its ramifications, of which we have a proof in dentition, from beginning to end. The untoward symptoms which this evolution may produce are usually divided into local and symptomatic. As intermediate between these, but having more especial relation to the latter, we regard sub-maxillary adenitis. We may justly wonder at the silence on this complication which almost all authors have observed when describing a host of affections of minor importance. It has, however, been noticed, and sufficiently insisted on, by Dr Piorry, who, in his 'Pathologie Iatrique,' says, "It is during the first dentition, and when the gums and the buccal mucous membrane are so frequently red and ulcerated, that we see tumefaction of the cervical glands occur in children; but still more frequently in the second dentition, and when the passage of the last of the molars, between twenty-five and thirty-five years of age, gives rise to ulceration of the gums."

Lisfranc, in a work unhappily unfinished, did not disdain to devote nearly the whole of a volume to minor surgery. He there says, "It is not unnecessary, perhaps, to tell young practitioners that the first dentition often occasions engorgement of the sub-maxillary lymphatic glands, and that these congestions have too long been ascribed to the existence of scrofula." Most authors speak only of the connection there is between adenitis and dental caries—a subject with which the present has nothing to do. It must be owned that a superficial lesion of the face or scalp may account for the glandular intumescence; but in some cases nothing can be referred to that cause, and the whole weight is thrown on scrofula, which most frequently does not exist, and here an examination of the state of dentition would have removed all doubt. This error of diagnosis is more common than will be believed, and happens to some who do not rank with *young practitioners*, though the illustrious surgeon of La Pitié has preferred addressing his remarks to such. Having been a witness of this mistake, we have taken some pains to ascertain with precision all the circumstances, and, from a great number of cases, the following propositions may, we think, be deduced:—

1st. When during the course of dentition no apparent lesion of the skin or mucous membrane can account for sub-maxillary adenitis, to regard dentition as the cause must be the rule, to which the scrofulous diathesis is the exception.

2nd. It is not necessary for the development of these tumours, that the buccal mucous membrane should be inflamed; *it is sufficient that the exit of the tooth be retarded.* The painful efforts then made by the dental bulb occasion a glandular reaction through the medium of the deep-seated lymphatics that creep under the inferior surface of the mucous chorion.

3rd. The iodide of potassium, *intus et extra*, and resolvents in general, combat the effects, without reaching the cause; and have few chances of success in adults, while in children they almost invariably fail, on account of the rapid course of inflammatory affections in so young subjects.

4th. This untoward symptom seems, in dentition, to hinder other symptoms from becoming so serious as they would be otherwise, though I do not say that this is any circumstance for gratulation.

The observations that precede are the result of the examination of children born of healthy parents, the children themselves perfectly healthy, and living under the best hygienic conditions.

Cutting the wisdom-tooth may give rise to the same affection of the glands, but in a much greater proportion. Of this the following is an example: In January last, a young man, 24 years of age, strong and active, who showed no evidence of the existence of any diathesis, was seized with an acute pain deep in his mouth, and great difficulty of deglutition; white swelling at the same time occurred in the left sub-maxillary region—symptoms that rapidly became worse. At my first visit, a week after, the following was the state of the patient:—high fever, loud and difficult respiration, inability to open his mouth or to swallow; well-marked torticollis, by which the head is turned to the right shoulder; under the left ramus of the maxilla, and stretching down nearly to the lower part of the neck, is a tumour the size of a goose-egg, tense and resisting, in the centre of which there is a portion of still greater firmness, of the size of a large walnut. The whole of this swelling is the seat of lancinating pains; but there is no fluctuation. Supposing the affection too far advanced to admit of resolution, cataplasms, sprinkled with laudanum, were ordered. Five days passed in atrocious suffering with threatening of instant suffocation, when, perceiving a fluctuating point, I made a puncture with a lancet, when a considerable quantity of consistent phlegmonous pus escaped, and continued at intervals to flow for nearly a week. Four days after opening the abscess, the patient was able to dispart the maxilla so far as to enable me to see the bottom of his mouth. The left lower wisdom-tooth had all but come through, and was surrounded with a very thick gingival border with unequal but not ulcerated lobes. His strength returned very slowly on account of the low diet he was obliged to observe, and more than a month elapsed ere the neck recovered its natural state. At this moment, four months later, the tooth which occasioned this adenitis is as high as its fellow adjoining; its gingival border has disappeared; but there is not yet any appearence of the other wisdom-teeth.

Numerous cases of this sort lead to the supposition that such are examples of idiopathic adenitis; or, should the pus have a bad appearance, of scrofulous adenitis. It would be interesting to know whether the affections of the cervical glands in young soldiers, attributed to the pressure of their military collars, &c.. may not sometimes depend on the cause under consideration, even where the tooth is still in the gum and undeveloped, as in the first dentition. On this point, however, I do not pronounce, and allude to it only as a subject for future inquiry.

As to treatment, you may try means for effecting resolution; but in children, as we have said, they usually fail. Where you are not successful, the next thing is to promote maturation; and when that is attained, to puncture—cataplasms and the lancet. Puncture, which is preferable to incision, should be practised as soon as fluctuation is perceptible. A tent need not be introduced, as it might prolong the suppuration beyond its just limits: but should the orifice contract too much, it may be daily enlarged with the bulb of a probe. This treatment is also the best in cases of scrofulous adenitis, and interferes in no measure with internal treatment. By not waiting for attenuation of the skin and spontaneous opening, you usually eschew every sort of scar; which in a child at the breast is of little importance, but which at a later period of existence may be of far greater moment.

Of the local symptoms occasioned by cutting the wisdom-teeth we would next speak, and first of all determine an important organogenic question. The providential reason for successive dentitions seems to be, to place the immediate organs of mastication in relation with the dimensions of the maxillæ by which they are borne; for were the teeth to remain permanently in the jaw, as the latter becomes enlarged, separation of the teeth from each other would necessarily follow, and difficult mastication would be one of the unfailing results. Hence the milk-teeth are deciduous, and give place to others of larger size. A similar principle is seen in the crustaceæ, as well as in many reptiles and insects, that at different times lose their inextensible cutaneous envelop, to become covered with another suited to each stage of growth. The lateness of the exit of the last of the molars, especially of the wisdom-teeth, is explained by the simple consideration that at an earlier period the alveolar margin is too

narrow in extent to contain them.(a) The growth of the maxillæ should therefore precede the second dentition. This enlargement both facilitates the fall of the milk-teeth, and the exit of the new and permanent teeth. But should the tooth be developed before the jaw-bone has acquired its proper size, there results a conflict between the tooth endeavouring to gain its exit and the alveoli that oppose it. The incisors and the canine teeth, not having room to rank in their natural situations, stand out obliquely, and remain permanently in that vicious position, though without causing much mischief; owing, perhaps, to the little thickness of the bone in this situation, and its comparative want of hardness at this early age. But the wisdom-tooth, when it becomes prematurely developed, has to overcome enormous resistance, for reasons the reverse of the above, and hence the severer symptoms to which it may give rise; and then extraction of the last but one of the molar teeth is to be recommended as the only means of facilitating its exit. But even this in some cases is not sufficient, and then the wisdom-tooth itself must be extracted—an operation that may present great difficulties should the tooth be imbedded in osseous tissue, as was doubtless the case in the instance mentioned by Lisfranc, where the patient suffered for thirty-five years, till the tooth was removed by M. Désirabode. When the resistance offered by the bone is once surmounted, the tooth in its passage through the gum occasions symptoms less formidable, but more frequent in their occurrence. A very acute pain may arise before the tooth has made the slightest appearance. In general, the mucous membrane opens anteriorly, showing some portion of the enamel, and is seen to be inflamed and ulcerated, and its margins covered with fungoid excrescences. It is under these circumstances especially that the adenitis of which we speak arises. It is now that a trifling operation practised on the gingival tissue becomes an expeditious means of relief, puts an end to suffering, and prevents every complication. A simple incision is made in form of the letter V, having the summit anteriorly. Lisfranc, however, preferred a crucial incision, or, in place of that, a simple incision with excision of the two flaps; alleging for reason, that often after simple division the tissues reunite; and that where they do not, the lateral flaps so formed become ulcerated and hypertrophied, and degenerate even to cancer, of which he had seen examples. But it is difficult, in spite of such imposing authority, to believe in this last transformation, which must under any circumstances be at least infinitely rare. Reunion of the wound can never take place if care be observed to prolong the incision sufficiently backward, and daily pass two or three times some soft body between the lips of the wound to prevent adhesion; and while proceeding thus, the gingival shreds themselves become absorbed. It is for these reasons we prefer a simple incision, which when practised on the lower jaw, where these affections are most frequently seen, should be carried to the bottom of the fossette bounded by the external and internal maxillary lines. The absence of considerable vessels in the track of this incision renders it a very harmless operation, and the slight pain which attends it is not comparable to that occasioned by cutting away several shreds. But for its execution, simple as it is, the ordinary straight bistoury is not the best instrument. In fact, if you cut from behind forward, and from above downward, (I speak of the lower jaw,) using the wisdom-tooth for a rest or fulcrum, you make an incision *with a tail*, less deep behind than before; besides incurring the risk of injuring the cutting edge of the bistoury against the crown of the tooth: and if, to avoid this inconvenience, you introduce the point of the instrument under the anterior edge of the gingival cushion, and direct it backwards and upwards, you are likely to impinge against the inequalities of the tooth, and the heel of the bistoury will be at the same time too much directed towards the opposite maxilla. The instrument which seems to me the best suited for this operation is M. Charrière's. It is introduced below the gum, and you carry the incision from before backward, cutting from the tooth to the surface. The point of the instrument being curved, you are able by this movement to avoid the inequalities of the crown of the tooth, and to divide the gum as far as you choose, and without *tails*. Should these minute details be thought tedious, we would only say that small things in the practice of Medicine are of every-day utility, that dental pathology is unjustly too much neglected, and that no part of his art is unworthy the attention of the practitioner.

(a) Cuvier, 'Leçons d'Anat. Comp.;' and Burdach, 'Traité de Phys.'

THE SPIRIT OF THE PERIODICALS.

'The Lancet' opens this week with a continuation of Dr Brown-Sequard's Lectures on *Paralysis*, in which are given the general conclusions of the course. We shall, therefore, extract the whole article:

"Before entering into the discussion of the general characteristics of the various forms of paraplegia, we will give here some statistical accounts that may be found interesting. The facts on which these accounts are grounded have all been observed by myself. We have left aside not only all the cases of paraplegia in which there were doubts as regards the diagnosis, but also those cases about which we have not kept a few notes.

"The following table shows the relative frequency of the various forms of paraplegia in men and women:—

	Men.	Women.	Total.
Myelitis	33	9	42
Non-inflammatory softening	25	8	33
Reflex paraplegia	19	6	25
Congestion	8	4	12
Tumour or pressure upon the cord	7	2	9
Spinal meningitis	6	1	7
Hæmorrhage	5	2	7
Hæmorrhage followed by myelitis	4	1	5
Hysterical paraplegia	...	4	4
	107	37	144

"These facts show that the most frequent causes of paraplegia are the inflammation and the non-inflammatory softening of the spinal cord. Next in importance, as regards frequency, is the reflex paraplegia. The most remarkable feature of this table is, that paraplegia is much more frequent in men than in women. This conclusion is borne out also by the cases about which we have not come to any positive diagnosis; out of 27 of such cases, 18 were men, and 9 women.
